The tendency of this undulation was, therefore, to bend the bearers into a form produced by the oblique intersection of a vertical plane with the surface of the moving wave. The bearers were not calculated to resist a strain of this nature: they therefore were fractured generally through the eyes on each side of the centre foot-path, at the point of junction with the suspending rods, which being bent backward and forwards where they were held fast at the surface of the roadway, were in many instances wrenched asunder also.

The means adopted for repairing these injuries, and for preventing the recurrence of them, were, placing a stirrup, with a broad sole, beneath each of the fractured bearers, attaching it by an eye to the suspending rod, cutting away the planking for an inch around the rods, and at the same time bolting, transversely, to the underside of the roadway, an oak plank, fifteen feet long, between each two bearers, for the purpose of giving to the platform a greater degree of stiffness, combined with elasticity, than it previously possessed. The four lines of main chains were also connected by wrought iron bolts passing through the joint plates, and traversing hollow cast iron distance pieces, placed horizontally between the chains.

The effects of these alterations were so beneficial, that little or no injury occurred for nearly ten years. On the 23rd of January, 1836, a more than usually severe gale caused violent undulation of the platform, and broke several rods. There can be little doubt that ten years' constant friction, combined with the shrinking of the timber, had relaxed the stiffness of the platform, and permitted an increased degree of undulation. The gate-keeper described the extreme amount of rise and fall of the roadway in a heavy gale to be not less than sixteen feet; the greatest amount of motion being about half way between the pyramids and the centre of the br[illegible]

In consequence of the injuries sustained during this [illegible] [illegible]. Rhodes were instructed to give in a report upon [illegible] and on any repairs or additions which might appea[illegible]

The result of the examination was satisfactory; the whole of the masonry, the main chains, their attachments to the rock, the rollers and iron work upon the pyramids, and all the principal parts of the bridge, were as perfect as when first constructed; it was, however, recommended, that "a greater degree of rigidity should be given to the roadways, so that they should not bend so easily under vertical pressure."

The bridge remained in the same state until the hurricane of the 6th and 7th of January, 1839; during the night of the 6th, all approach to the bridge was impracticable; the bridge-keeper, however, ascertained that the roadways were partially destroyed; and he in consequence traversed the strait in a boat in time to prevent the down mail from London driving on to the bridge.

When the day broke, it was found that the centre foot-path alone remained entire, while both the carriage ways were fractured in several places. The suspending rods appeared to have suffered the greatest amount of injury; out of the total number of 444, rather more than one-third were torn asunder; one piece, 175 feet long, of the N.E. carriage way, was hanging down and flapping in the wind; much of the parapet railing was broken away; the ties and distance pieces between the main chains were destroyed; the chains had resisted well in spite of the violent oscillation they had been subjected to, to such an extent, as to beat them together and strike the heads off bolts of three inches diameter.

Means were immediately adopted for restoring the roadways; and so rapidly was this effected, that in five days carriages and horses passed over, while foot passengers were not at any time prevented from crossing.

The account of the restoration of the bridge, communicated by Mr. Maude to the Institution, is then alluded to.

The substance of the report of the author to the Commissioners of Her Majesty's Woods is then given, and a review of the proposals made by Mr. Comms, Colonel Pasley, and others, relative to the restoration.

The opinion of Colonel Pasley, "that all the injuries which have occurred to the roadways of Suspension Bridges must have been caused by the violent action of the wind from below," is then examined, and reasons given for the author's dissent from that opinion.

The action of the wind upon the Conway and Hammersmith Bridges, is next examined; and from the amount of oscillation observed in all suspension bridges, the conclusion is arrived at, that winds act strongly and prejudicially on the fronts as well as on the horizontal surfaces of the platforms of suspension bridges, and that the effect of winds is modified and varied by the nature of the country, and the local circumstances connected with each individual bridge. Although differing in opinion with Colonel Pasley as to the general cause of injury to suspension bridges, the author agrees with him in the propriety of giving increased longitudinal rigidity to their platforms, to prevent or to restrict undulation. He advised its adoption in 1836, and applied his plan of stiffening by beams, in 1839. He preferred beams to trussed framing, on account of the facility with which the former could be increased in number, to obtain any requisite degree of stiffness, and because he feared that trussed frames could not always be kept firmly in their true vertical positions.

A drawing showing the injuries sustained by the platform during the hurricane of 1839, accompanied the communication.

Mr. Cowper was of opinion, that the real cause of injury to suspension bridges was the vibration of the chains and roadway. The whole suspended part, when acted upon by the wind, became in some measure a pendulum, and if the gusts of wind were to recur at measured intervals, according either with the vibration of the pendulum, or with any multiplies of it, such an amount of oscillation would ensue as must destroy the structure. He illustrated this proposition by a model with chains of different curves, and at the same time pointed out the efficiency of slight brace chains in checking the vibration.

Mr. Brunel agreed with Mr. Cowper in his opinion of the cause of injury to bridges, and with the propriety of applying brace chains, for preventing the vibration. He then alluded to the introduction of lateral braces in the bridge designed by Mr. Brunel, senior, for the Isle of Bourbon. He had been at the Menai Bridge during a severe storm, and had particularly noticed the vibration of the chains with the accompanying undulation of the platform. The force of the wind was not apparently from beneath; it appeared to act altogether laterally. The chains were too high above the roadway; their vibration commenced before the platform moved: the unequal lengths of the suspension rods then caused the undulating motion. His attention had latterly been much given to the subject on account of the Clifton Suspension Bridge, now erecting under his direction. The span would be seven hundred feet, and the height above the water about two hundred feet. He intended to apply the system of brace chains at a small angle to check vibration. To two fixed points in the face of one pyramid would be attached two chains, each describing a curve horizontally beneath the platform, touching respectively the opposite sides of the centre of the bridge, and thence extending to similar points on the other pyramid: there they were attached to two levers, the ends of which were connected with a counter balance of about four tons weight appended to each; these weights would hold the chains sufficiently extended to enable them to resist the lateral action of the strongest winds without their being so rigid as to endanger any part of the structure. By this contrivance the platform would be kept firm, which was the chief point to be attained.

In all suspension bridges the roadways had been made too flexible, and the slightest force was sufficient to cause vibration and undulation. The platform of the Clifton Bridge would have beneath it a complete system of trough-shaped triangular bracing, which would render it quite stiff. He was an advocate for bringing the main chains down to the platform, as at the Hammersmith Bridge, and for attaching the bearings to the chains at two points only; when they were suspended by four rods, it not unfrequently happened that the whole weight of a passing load was thrown upon the centre suspension rods, and the extremities of the bearers were lifted up and relieved from all pressure. The extent of the expansion and contraction of the chains was a point of importance. In the Menai Bridge the main chains on a summer day would be as much as sixteen inches longer than in a winter's night. At the Clifton Bridge the difference under similar circumstances would be about twenty inches. The whole expansion of the back chain beyond the pyramids must be thrown into the suspended part. He would prefer having only one chain on each side of the bridge, and that chain much stronger than is usually adopted, but in deference to public opinion he had put two; he believed that they rarely expanded equally, and hence an unequal distribution of the weight of the roadways upon the suspension rods occurred. A rigid platform would in some degree prevent this, but he had endeavoured to lessen the effects of unequal expansion by arranging a stirrup at the top of each suspending rod, so as to hold equally at all times upon both the chains, and thus cause each to sustain its proportion of the load.

Mr. Seaward had never seen the force of wind exerted at regular intervals, as Mr. Cowper had supposed; if the gusts were repeated at such intervals, no suspension bridge, nor any elevated shaft or chimney in masonry, could resist them.

Mr. Rendel believed that the errors committed in the construction of suspension bridges had principally arisen fron engineers theorizing too much on the properties of the catenary curve, without attending sufficiently to the practical effects of wind in the peculiar localities in which the bridges were placed. He could not agree with Mr. Cowper in his view of the intermittent action of the wind, or the vibrating of the chains. Observation had led him to conclude that, in the positions in which suspension bridges were usually placed, the action of the wind was not uniform; for instance, it would act at the same moment on the upper side of one end of the roadway, and on the lower side at the other end. In this case, unless the platform possessed a certain degree of rigidity, undulation was induced and oscillation ensued. Braces and stays would not counteract this—nothing but a construction of platform, which made it in itself rigid by some mode of trussing, could withstand this kind of action. He agreed with Mr. Brunel in his idea of reducing the number of the suspending chains. At the Montrose Bridge, which was 432 feet span, he had endeavoured to avoid all complexity of contrivances by adopting a complete system of vertical diagonal trussing, which was ten feet deep—five feet above, and five feet below the platform—so as to insure rigidity, and to produce that solidity which was essential for preventing undulation and oscillation.

Mr. Cowper reverted to the motion which he had found to be so easily produced by repeatedly exerting a small force at measured intervals against the main chains of the Hammersmith Bridge. He conceived that if the chain oscillated, the roadway must oscillate also.

Mr. Rendel contended that the motion produced by the impulses communicated by Mr. Cowper to the chain resolved itself into undulation, and not oscillation. He could not understand the advantages of the trussing adopted at the Hammersmith Bridge: it appeared to him that its tendency was, on the passage of a heavy weight, to relieve four out of five of the suspending rods from their due proportion of the load, and to throw it upon the fifth rod. His object in the construction of the framing of such platforms had always been to spread the load quite equally, and rendering it rigid by means of vertical trussed framing, to prevent the undulation which was the primary cause of oscillation. He would distinguish clearly between the two motions, and say, that undulation was a motion in the direct line of the platform, and that oscillation was a motion at right angles with it. Vibration was identical with undulatory action.

Mr. Donkin conceived that a good system of trussed framing could alone prevent undulation or oscillation; if the framing were placed vertically, its tendency would be to prevent undulation; if placed horizontally, to prevent oscillation: now, as Mr. Rendel had given it as his opinion, that the latter action resulted from the former, the system of trussing adopted by him at the Montrose Bridge would appear calculated to obtain the desired end. A slight exertion of force would produce a perceptible undulation, and a certain degree of vibration would result from the natural elasticity of the materials.

Mr. Seaward remarked, that the degree of oscillation would appear to depend in some measure upon the distance at which the platform was suspended beneath the chains, and upon the distance between the points of suspension of the main chains; if the platform were rigidly held at the extremities, the motion would be vibratory, and not amounting to undulation.

The railway tickets on the Manchester and Leeds line, invented by Mr. Edmondson, are printed by a machine which gives each a progressive number, and arranges them in order. Two boys lately printed 10,000 tickets in four hours.

THE PRESIDENT'S CONVERSAZIONE.

The general conversazione of Mr. Walker, the President of the Institution of Civil Engineers, took place on Wednesday evening, 12th ult., and was distinguished by the same features of interest which always render this one of the most remarkable reunions of the season. The suite of rooms was embellished by works of art of almost every class, extending from the production of the golden age of art, down to those of the aspirants of the present day. Amongst other objects of this description, which were scattered in profusion through the spacious though crowded area, we particularly noticed several admirable busts by Park, Belines, and Smith, together with one of the host himself, modelled in clay by Mr. J. E. Jones, an amateur whose talents, if he had not already chosen a profession in life, would certainly entitle him to shine in this department of art. The portfolios of drawings by Varley, Hering, Tomkins, Fripp, and Kendrick, and the paintings by Scanlan and John Wood, excited great attention, and elicited corresponding praise. A new etching by Thomas Landseer, the first proof of his brother Edwin's picture of Count d'Orsay's dog "laying down the law," was displayed amongst these objects of art. Nor ought the unrivalled vases and bronze figures, the work of the eccentric Florentine artist of the 15th century, of Clodion and others of later date, to be passed over in silence. There were also some of Goddard's fine Daguerréotypes, some electrotypes, as also some specimens of Cheverton's beautiful mechanical sculpture. The most striking of the useful novelties were samples of coloured glass from Mr. Apsley Pellatt's manufactory, some ornamented slabs, &c., of slate from Magnus's Pimlico works. Atkinson's patent ornamental wood mouldings, which are equal to carved work; Pole's new hygrometer. The principal feature, however, of Mr. Walker's soirée was the exhibition of models of machines, &c., which were, throughout the evening, the chief focus of attraction. It is impossible, within the limits of an ordinary notice, to afford any thing like an adequate epitome of the various ingenious and highly useful, as well as valuable, novelties which attracted the attention of the guests on all sides. The model of the lighthouse erected on the Maplin sands at the mouth of the Thames, by Mr. Walker himself, obtained very great attention, a description of which appeared in the last number of the Journal. Mr. Hicks' radial drilling machine, his compound hydraulic press, and new governor, &c. Messrs. Seawards' beautiful models of marine steam-engines, the slide-valves, the disconnecting apparatus for paddle-wheels, and the brine detector, Barnes' paddle-wheel, and the model of the Castor steamer. Mr. Dent's electric and central percussive clocks, Mr. Gossage's disc steam engine, Messrs. Whitworth's (of Manchester) street cleansing machine, cutting tools, &c., Messrs. Ransome & May's railway chairs, Dr. Schaffhaeutl's new universal photometer, a sectional drawing of the Thames Tunnel by Sir Isambart Brunel, and a vast assemblage of other beautiful adaptations of the chemical, electrical, and mechanical branches of science to the purposes of utility and ornament, excited the admiration and occupied the untired attention of the stream of visitors for several successive hours. The conversazioné was attended by most of the distinguished amateurs and professors of science and art, and notwithstanding the eventful debate in the House of Commons, which was proceeding at the same time, and which occupied all the peers and members of Parliament, and the Literary Fund dinner, which detained many of the usual visitors, the numbers who availed themselves of this opportunity of testifying their love of science and esteem for the distinguished President, was very great.

Among the company we noticed, besides the council and a large number of the members of the Institution, the chief members of almost all the scientific societies of the metropolis:—The Marquis of Chandos, Lord Henneker, Admiral Adam, Barons Schleinitz and Bulow, Colonels Pasley, Maclean, Lieut. Colonels Blanshard, R.E., Hutchinson, Major Anderson, Sirs J. J. Guest, M.P., Frederick Pollock, M.P., Wm. Symons, John M'Neil, Isambart Brunel, George Murray, Walter Riddell, Henry Parnell, M.P. Edward Knatchbull, M.P., Chas. Price, Harry Verney, M.P., John Scott Lillie, Chevalier Benkhausen, Captains Laird, Ivanetskey, Locke, Willis, Scanlan, Pringle, R. Wellbank, L. Price, Kincaid, Smith, G. Smith, R.N., Evans, R.N., R. Drew, Drs. Paris, Schaffhaeutl, Elliot, Field, Pollock, Arnott, Walker, Billing, Roget, Bowring, Rigbey, Reid, Professor Willis, Messrs. E. R. Rice, M.P., Pryme, M.P. F. Hodgson, M.P., Ormsby Gore, M.P., G. F. Young, M.P., Emerson Tennent, M.P., Mr. Justice Haggerman, of Canada, Messrs. T. Landseer, F. P. Stephanoff, Behnes, Tomkins, J. Varley, E. H. Bailey, F. Stone, G. Rennie, Fripp, Rivers, Jun., Hakewell, R. Scanlan, Sargey, A. Cunningham, Oliver, Page, S. Howell, W. Boxall, C. Landseer, Macready, Barry, Sydney Smirke, Tite, Donaldson, Hopper, and Poynter.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

Monday, May 3.

The annual general meeting of the Institute was held for the purpose of electing the council and officers for the ensuing year. Earl de Grey in the chair.

The report of the council and the annual balance were presented, and exhibited a highly favourable view of the progress of the Society.

Monday, May 17.

A paper was read by Mr. G. F. Richardson, of the British Museum, on the subject of geology as connected with architecture. After a prefatory sketch of the general stratification of rocks, Mr. Richardson adverted more especially to the stratum and quality of those in most general use as building materials. The lecture was illustrated by the exhibition of various objects connected with the subject in the oxy-hydrogen microscope.

Messrs. Pontifex and Co. exhibited a new construction of a self-acting water closet.

ROME AT THE SURREY ZOOLOGICAL GARDENS.

The mimic volcanic flames of Hecla, Etna, and Vesuvius, are now extinct at the Surrey Zoological Gardens, and we have another giant wonder from the burning climes of the South. When we heard that Rome was to be portrayed to the gaze of the successor of its greatness, we were naturally anxious to ascertain whether it had a fitting representative; Mr. Cross has succeeded very well in housing lions and tigers and elephants, but where he was to pitch down the Eternal City we could not readily conceive. He has, however, by placing it near the lake found means to appropriate to it a space of five acres, a space large enough to hold a modern town, and to do justice to the object of this representation. We have here a pictorial model, covering a surface of more than a quarter of a million of square feet, and presenting, as has been well stated, "a stupendous panoramic view, and the largest picture or model ever produced." The lake now stands for the Tiber, and across it we have the bridge of St. Angelo, with its statues of angels on the walls. Beyond are seen on the left the Tordinona Theatre, the Palazzo Tortonia, and other well known edifices. On the right the Mole of Hadrian, now the Castle of St. Angelo, raising its giant bulk. Farther behind, rising over every thing, is St. Peter's, upwards of a hundred feet in height, and appearing as magnificently as its great original. The façades of the Vatican, the Papal Palace, the Ospitale di Spirito Santo, and many other structures well known to fame are strikingly represented. To be properly appreciated this exhibition must be seen; the apparent solidity and verisimility of the structures, the extreme range of distant view, are features which tend to impress us with a sense of the reality of the objects before us. The painting is good, free from glare and exaggeration, and subdued so as to give that sobriety and real life, which augments the impression on the spectator; we think however that the effect might have been increased by a few figures of men and animals being appropriately introduced. The artist is Mr. Danson, and in naming him we do quite enough to show that full justice has been done to the subject, for his reputation in this department of art is a guarantee of the extent of his exertions. We may indeed assure our friends that those among them well acquainted with the Eternal City will be gratified in renewing their recollections of it, and those who have the pilgrimage yet to make, cannot have a better introduction than by a visit to this, its prototype.

NEW INVENTIONS AND IMPROVEMENTS.

IMPROVEMENTS IN STEAM ENGINES.

George Henry Fourdrinier and Edward Newman Fourdrinier, of Hanley, Stafford, paper makers, for certain improvements in steam engines for actuating machinery, and in apparatus for propelling ships and other vessels on water.—Rolls Chapel Office, March 17, 1841.—These improvements are, as the title explains, divided into two parts; the improvements in steam engines consist in applying and working two pistons in one cylinder, which are simultaneously actuated by the expansive force of the same volume of steam. A long cylinder is supported vertically on pivots, in the middle of which it vibrates; two pistons are attached to piston rods which pass out through stuffing boxes at either end of the cylinder. On steam being admitted through suitable slide valves to the middle of the cylinder, the two pistons are forced apart towards the opposite ends of the cylinder, the valves are then shifted, and the steam admitted at the two ends of the cylinder, which drives the piston back again to the centre, the spent steam passing off to a condenser or into the atmosphere, and so on continually. The lower piston rod is attached to a crank in the middle of the shaft, while the upper piston rod carries a cross head from which connecting rods pass down to two cranks placed on the same shaft, but opposite to the former, so that as the one is descending the other is ascending, in conformity with the opposite motion of the pistons. In another arrangement, the cylinder is divided into two parts by a partition in the middle, and the pistons do not expand simultaneously as in the former case, but the one piston begins to move when the other is at the quarter stroke, the valves being so adjusted as to effect this movement; for the purpose of overcoming the dead points, when one piston is at the dead point the other is exerting its full force. The apparatus for propelling ships and other vessels consists of certain arrangements of mechanism by which a volume of air may be forced against the water at the bottom of the vessel, in the direction of its stern, for the purpose of impelling the vessel in an opposite direction. The air being compressed by an air pump, "to the same density as the water under the ship's bottom," is admitted through a valve into a tube, down which it flows into the water. The bottom of the vessel has two guards of wood or other material, parallel to its keel; as the air enters the water beneath the vessel it is guided by the guards, which prevent it from escaping at the sides, and by its pressure against the water, in the direction of the stern, impels the vessel head foremost. The direction of the air, backward or forward, is regulated by a tumbling valve, worked by a quadrant rack or sector, and an endless screw; by altering the position of this valve the direction of the air, and, consequently of the vessel, may be reversed at pleasure. When the vessel rolls about in a heavy sea, it is considered desirable to force the air under the most depressed side of the vessel only; to effect which the air plugs are connected to a pendulum which opens the valves on the one side or the other, according to the position of the vessel. In another arrangement for reversing the motion of the vessel, two sets of sliding tubes descend from the air chambers, opening fore and aft; if the vessel is to be propelled head first, the two hinder tubes are depressed and the air passes off towards the stern; but if the vessel is to be backed astern, the foremost tubes are depressed and the air projected towards the head of the vessel. The claim is—1. To the application of two pistons working in one cylinder, as shown.—2. For propelling vessels, by forcing a volume of air against the water beneath the bottom of the vessel, in the manner shown and described.—*Mechanics' Magazine.*

MOVEABLE OBSERVATORY AND SCAFFOLD.

Alexander Horatio Simpson, of New Palace-yard, Westminster, Middlesex, gentleman, for a machine or apparatus to be used as a moveable observatory or telegraph, and as a moveable platform in erecting, repairing, painting, or cleaning the interior or exterior of buildings, and also as a fire escape. Enrolled May 5.—Claim first. The use of a shaft or spar as herein described, with a gallery or platform suspended or attached so as to be capable of being raised or lowered on the shaft by a power, either manual or otherwise, exerted within the platform.

This machine consists of a shaft or spar, mounted in a step, in which it is capable of turning (the step being fixed to a foot or pediment), and supported laterally by stays, jointed at their upper ends to a collar, which slides on the shaft, but is retained in any required position by a pin. The lower ends of the stays fit into holes in the foot or pediment, so as to admit of the stays altering their position or angle, in relation to the shaft, and thereby supporting it in different positions. The shaft is constructed of wrought iron plates, rivetted together, and one side of it is formed by a rack sunk flush with the surface of the shaft, which rack may be of cast iron; but one of the lantern form is preferable, the teeth of which is formed by long bolts or rivets, running across in the same position as the teeth of the cast iron rack. On the shaft is a sliding frame, to which is attached a gallery for the reception of workmen, tools, &c., and this sliding frame is fitted with a pinion, which working in the rack of the shaft raises or lowers the gallery or platform, according to the direction in which it is turned.

This machine may be used as a telegraph, by having the usual apparatus attached to the top of the shaft, or it may be used as a moveable observatory.

Claim second.—The use of a horizontal suspension rail, supported by shafts or spars, with a platform or gallery suspended therefrom, capable of receiving motion from within the gallery.

Claim third.—The giving motion to the gallery or platform, by the application of a power, either manual or otherwise, from a point not within the gallery or platform.

This part of the invention is an improved construction of scaffolding, and consists of two shafts, placed one on each side of the front of the building, similar to that before described, but without the rack and platform with its appendages. On the top of these shafts is fitted a cross rail, on which is mounted a carriage running on flanged wheels, and to these wheels are fixed two "gallows," suspending a light ladder by a pin or bolt. On the centre of this bolt is a roller or pulley, over which a rope passes, one end of it being fastened to a gallery similar to that before mentioned, and sliding on the ladder, and the other end to a counterpoise weight. On the foot of the ladder there is another roller, that runs on a cross bar, similar to the bar at the top, but which roller supports none of the weight of the ladder, as it rolls nearly horizontally and against the side of the bar, being provided for the purpose of permitting the ladder to travel easily to and fro.

In order to bring the gallery to bear on any portion of the surface of the building that the workman may require, four ropes are provided; two of these are fastened to the bottom of the shafts, and passing over two live pulleys at the foot of the ladder, proceed up to the gallery; the other two are fastened to the top of the shafts, and pass over two live pulleys, on the same axletrees as the wheels of the carriage before mentioned, into the gallery.

Now if the person in the gallery pulls the two top ropes, he raises the gallery, or if he pulls the two bottom ropes, he lowers it; if he pulls either of the two side ropes, namely, those attached to the same shaft, leaving the other two side ropes loose, the gallery and ladder will move horizontally in a lateral direction.—*Ibid.*

DRIVING BELTS AND STRAPS.

James Heywood Whitehead, of the Royal George Mills, near Saddleworth, Yorkshire, manufacturer, for improvements in the manufacture of woollen belts, bands, and driving straps. Enrolled May 2.—This invention consists in applying a composition to a woollen belt to give it firmness and adhesiveness, as a substitute for leather for driving machinery.

The composition consists of linseed oil and resin mixed together, in the proportion of three pounds of linseed oil to two pounds of resin; but these proportions may be varied a little to suit circumstances. The oil is first boiled, and the resin in fine powder added to it while it is in the boiling state, being well stirred till they are thoroughly mixed together.

The belt or strap is passed through the mixture and between two rollers, which are weighted sufficiently to make the composition even, so that it will not run out of the cloth when hung up. The cloth is then well stretched in length and dried, after which it is ready for use.—*Inventors' Advocate.*

RAILWAY CARRIAGE.

James Boydell, jun., of Cheltenham, ironmaster, for improvements in working railway and other carriages, in order to stop them, and also to prevent their running off the rails. Enrolled May 2.—Claim first. The mode of applying apparatus acting by lever pressure on rails, as a means of stopping carriages, as herein described.

Beneath the lower part of the railway carriages a projection is affixed, carrying the axis of a lever, the lower end of which lever is enlarged and embraces the rail, the part which comes against the rail being lined with wood, to enable it to offer greater friction. This part of the lever is, by means of another lever, and connecting links, brought in contact with the rail, whenever it is desired to stop the train.

Claim second.—The mode of applying bars to prevent carriages running off the rails of railways.

Beneath each carriage are two bars, which extend across from opposite corners of the framing of the same, crossing each other beneath the centre of the framing, and from which centre they are suspended by means of a pin passing through a slot formed in the centre of each bar. The ends of the bars are connected by pins to the ends of the bars of the carriages before and behind them, thus forming a continuous bar, which will in most cases prevent the carriages from getting off the rails, and in case one of the carriages should run off the rails will prevent it from running at any considerable angle to the same. The slots in the bars have sufficient play to permit the train to move over curves easily.—*Ibid.*

MR. GRANT'S PATENT FUEL FOR STEAM BOATS.

We learn with great satisfaction, that this important invention is at last to be brought into general use. The Admiralty, after a long series of experiments made under their directions, by Mr. Grant, and followed up by frequent trials of his fuel in her Majesty's steam vessels, instructed him some time ago to take out a patent, chiefly, we suppose, to secure themselves and the public against the interference of any pretenders to the invention.—This point being settled, it became the wish, as it was the obvious duty of government, to extend the benefits of Mr. Grant's labours to the country at large.

Numerous applications having been made to Mr. Grant, by the various steam vessel companies, for permission to make use of his patent, the Admiralty, in a spirit of enlarged policy, have, as we understand, directed that gentleman to refer all persons to them who desire licenses to manufacture his fuel—and we have no doubt that their Lordships sanction will be given accordingly. But, we trust, the terms will be so moderate as to render it the interest of those extensive companies, whose vessels now cover so many seas, to employ this new agent for the production of their steam power.

A word or two on the nature and properties, as well as the practical advantages of Mr. Grant's fuel, will probably not be unacceptable to our readers generally, and may prove useful to such persons as are engaged in steam boat enterprises on the large scale.

It is not our purpose, nor would it be proper, to describe minutely Mr. Grant's process—it will be enough to say, that his fuel is made of coal-dust and other ingredients, mixed together, in certain definite proportions, and then fashioned, by a peculiar process, into the shape and size of common bricks. The advantages of Mr. Grant's patent fuel over even the best coal may be stated to consist—first, in its superior efficacy in generating steam, which may be stated in this way—200 tons of this fuel, will perform the same work as 300 tons of coal, such as is generally used;—secondly, it occupies less space, that is to say, 500 tons of it may be stowed in an area which will contain only 400 tons of coal;—thirdly, it is used with much greater ease by the stokers or firemen than coal is, and it creates little or no dirt, and no dust—considerations of some importance when the delicate machinery of a steam engine is considered;—fourthly, it produces a very small proportion of clinkers, and thus is far less liable to choke and destroy the furnace bars and boilers, than coal is;—fifthly, the ignition is so complete, that comparatively little smoke, and only a small quantity of ashes are produced by it;—sixthly, the cost of the quantity of Mr. Grant's fuel required to generate in a given time a given amount of steam, is so much less than that of the quantity of coal which would be consumed in effecting the same purpose, that, even if the advantages of stowage, cleanliness, and facility of handling, were not to be taken into the account, the patent fuel would still recommend itself to the attention of all steam boat proprietors.—*Hampshire Telegraph.*

[The first part of this statement appears to us rather extraordinary that the Lords of the Admiralty should interfere with the working of a patent in any kind of way, and that parties requiring licenses are to be referred to them; surely there must be some mistake in the statement.—Editor C. E. and A. Journal.]

APPLICATION OF ELECTRO-MAGNETISM TO MACHINERY.

(From the Leipsic Allgemeine Zeitung.)

Leipsic, April 17.

The meeting of our Polytechnic Society was rendered peculiarly interesting by a lecture given by Herr Störer on his experiments in the application of electro-magnetism as a motive power. Herr Störer commenced his experiments several years ago, before Wagner's invention, and has proceeded independent of it. By merely following up and carrying out the ideas of Jacobi, to whom the first merit of the discovery is due, he has succeeded in constructing a small machine, the power of which is as yet limited to the raising of only a moderate weight and putting a turning lathe in motion, but which is nevertheless sufficient to render perfectly evident the whole mechanism of the important invention, and which, as the constructor observed, needs only to be enlarged to produce more practical effects.

The principle of electro-galvanic movement has its source, as is well known in the law of reciprocal attraction and repulsion of two iron bars, surrounded by a galvanic current, alternating with positive and negative electricity, and thereby magnetized. Herr Störer's machine consists at present of only two concentric circles of spiral iron bars, surrounded by conducting wires for the reception of the electric current. Each circle contains 12 single bars, placed at the distance of from 2½ to 3 inches from each other, the bars of the outer circle being about half an inch separated from those of the inner. The outer circle is fixed; the inner forms the periphery of a moveable disc, swinging wheel, or pinion. This mechanism is brought into connexion by two conducting wires with a galvanic battery, in such a manner that in the first place the bars of the one circle with positive electricity surround those of the other with negative electricity; then suddenly, by an arrangement in the conducting apparatus, the current is changed, and thereby electricity of the like name is produced in both circles. The consequence of this is, that the opposite bars, in consequence of the different magnetic power communicated to them, first attract each other, then instantly becoming, by the inversion of their poles, similar magnets with equal force, repel each other. By this regularly repeated alternation of attraction and repulsion, each bar of the internal moveable circle is in succession drawn towards all the bars of the external fixed circle, and then driven as it were back on the next, whereby the whole disc is brought into a state of uniform motion.

The inventor makes a very moderate estimate of the cost of the machine. The expense consists chiefly in the wear of the zinc in the galvanic battery, by the action of the acid; but as to the outlay for this article, it will be almost entirely counterbalanced by the precipitate which in consequence of the operation is formed in the acid, and which yields a somewhat valuable chemical product. With regard to the power of the machine, and the possibility of reinforcing it so as to produce greater practical effects, Herr Störer submits the following considerations:—The present machine, though only double the size of the one he first constructed, which had only six pair of bars, acts with a sixfold increase of force. Each galvanic element consists of a copper cylinder, a zinc cylinder within it, and a chemical mixture by which they are connected. Now, as respects the effect of the number of elements employed, Herr Störer makes the following observations, the accuracy of which he has proved by experiments:—"In the connexion with a single element the machine raises, with moderate velocity, 3 lb.; with two elements, 13 lb.; with three, 25 lb.; with four, 40 lb. This is approximatively an ascending gradation of power in the ratio of 1, 4, 8, 12, whence it certainly would appear that the force might not be found to augment exactly in the relation of a progressive increase of the elements." According to Herr Störer's calculations, the connexion of a battery of 50 elements, with a machine in cubical contents 26 times greater than the one exhibited, would produce an effect equivalent to 50 horse power.

Still, however, after all these data and calculations, there remain several doubts as to the practicability of the application of this invention to machinery on an extensive scale. On the other hand, the results obtained by the experiments hitherto made are of sufficient importance to encourage a spirited prosecution of the discovery, which is in itself so ingenious, that it ought to be joyfully hailed by all who take an interest in the progress of civilization, as a new triumph of the human mind over inanimate matter. At all events, we Germans have just reason to be proud of an invention the first idea of which came from a German, and all the improvements yet made in which are the offspring of German intellect and German perseverance.

CONTINENTAL MODE OF BORING, BY APPLICATION OF THE ROPE.

When I was lately residing on the Continent, I occasionally observed notices in the foreign papers of this mode of boring, with flattering accounts of its advantages. I was anxious to obtain information about it, but I did not succeed in doing so until I perused the official report of M. Jobard on the Paris exhibition of 1840 His account is, indeed, in some degree, defective, as it does not furnish diagrams of the instruments; nevertheless, it gives a general view of the method, which seems to be attended with the surprising benefit, that the expense of the bore per fathom does not increase in any considerable degree with the depth of the bore. Having both observed and experienced the cost, danger, and tardiness of the bore with boring rods, when a great depth is reached, I have found M. Jobard's report interesting and instructive; and, therefore, as the subject may be new to some of your readers, I venture to send you the substance of it, in case you think it worth insertion in your valuable Journal.

There are in all three instruments, or tools, used in the method alluded to—the *mouton*, *emporte piece*, and *alezoir*. The *mouton* is a cylinder of cast-iron, of about eight inches in diameter and thirty-nine inches in height—weight from one to three cwt. This cylinder has exterior flutings, 4-10ths of an inch in depth and 6-5ths of an inch in breadth; the upper part contains an empty cone, whose base is reversed, which gives it the form of a bucket with thick sides. There are two handles to the cylinder, one above the other—if the first should break, the second retains the rope. The lower part of the tool is prepared to receive a number of steel chisels, which are fixed by a transversal key. The tool should be composed of as few pieces as possible, for, however well they are fixed, the percussion tends to detach them, and to leave them at the bottom of the hole. The best way of procuring good moutons of percussion, for hard strata, is to make them all of one piece of case-hardened cast iron, with handles of malleable iron hooked into the cast iron. These handles should be high up, in order to facilitate the extraction of the powdered stone, which accumulates in the empty part of the mouton. The head, or top, of the tool should exhibit a number of pyramidal points, projecting about an inch, diamond-pointed, the better to cut into the stone. The case-hardening gives them the hardness of tempered steel, and makes them last a long time. A mouton of three cwt. costs only 50f. (2l.); when it is worn, the old metal serves for the casting of others. The rock is cut daily to the depth of at least 39 inches. The rope is worked by a long plank placed obliquely, the upper end being about 12 or 15 feet above the hole. The mouton is suspended about 15 or 20 inches from the bottom of the hole. Motion is given to this plank by the hands or the feet, or by several men pulling together by ropes attached to the plank. There are also several other ways of working the main rope.

In boring with boring rods, four or five hours are required to draw them and lower them again; but all this is done (when the bore by means of the rope is used) in eight or ten minutes. In this latter, then, the progress of the work is always nearly the same—at 3000 as at 100 feet. The same number of men, too, is sufficient to work it, let the depth be what it may. What takes place, is as follows:—The mouton, falling 25 or 30 times a minute, from a height of two or three feet, readily breaks and pounds the rock. The dust or powder which results from this would soon deaden the blow, if there were no water in the bore hole, but there is almost always some—if not, it should be thrown in. The water and the dust form a magma—a mortar or mud, which spouts up by the flutings carved around the mouton. This mud falls back necessarily on the head of the mouton, and, as this is hollow, the mud enters a little at every blow. This powdered stone heaps up in the interior of the cone, by the work, to such a degree, that force is often necessary to get out the stony sugar-loaf which is there concreted after some hours striking. The contents of the instrument are known; it is sufficient, then, to put a mark on the rope, at such a height, to know that, when the rope has lowered a certain distance, a certain number of inches of matter have passed from below to above the tool. Before retiring the mouton it should be left at rest one or two minutes, to allow the heavier particles of the mud, which are in suspension at the bottom of the bore hole, to deposit themselves in the bucket—but not longer, for so it might get it incrusted.

The mouton alone suffices to the Chinese to bore to the depth of 1800 feet. Their strata are hard and solid enough not to require tubing, but it would not do for clay, sand, or pebbles—in that case the *emporte piece* is requisite. It is a cylinder, which has at its base two valves, turning on a hinge in the diameter, in the form of the wings of a butterfly. This cylinder is lowered to the bottom of the hole, and is caused to penetrate the strata by the intermediate percussion of a mouton, of the weight of 65 lbs., which is made on purpose for the emporte pièce. The mouton, having an aperture in the centre, slides for some feet along a metallic rod, which is fixed to the emporte pièce. When the mouton is raised, it gets as far as a bolt, which stops it; it then falls on the emporte pièce, which latter sinks at every blow, and its valves open to let the mud pass. When it is thought the instrument has sunk far enough, it is drawn up, and it arrives with a cake of mud, &c.; but care should be taken not to allow it to sink too far into plastic clay—it might then be difficult to draw it out. For strata which require tubing, there is, besides, the *alezoir*. The following is the simple artifice employed to enlarge the bore hole when it is tubed (or, to resolve the problem, to form with an instrument, which is obliged to pass through a tube, a hole larger than the exterior of this tube):—The tube is supported by straps, at about two lengths of the mouton from the bottom of the hole. The mouton used in this case has a square, and not a round, handle at its upper part. It is easily conceived that, if the rope is fastened to the middle point of the handle, which corresponds to the centre of gravity and to the centre of figure, the mouton would strike straight, and would only form a hole equal to the diameter of the instrument or the interior diameter of the tube; but if the point to which the rope is fastened is borne away one or two inches from the middle point of the handle, the centre of gravity becomes displaced, and the lower part of the mouton inclines to the right or left—a position which causes it to [illegible] and wear away the sides of the hole with its crown, at the same time that it attacks the bottom with its steel teeth. When this instrument, which is slightly conical, is drawn up, it sets itself straight again and rises up in the tube, exercising a feeble friction on the sides of the tube. This mouton, like that for the strata, which require no tubing, has a receptacle for the mud. In using either mouton, a movement of torsion must be impressed on the rope. This is effected by fixing the rope into the extremity of a wooden bar, of about two feet long, which gives a workman sufficient leverage to turn or twist the cord a little at every blow, or to regulate its untwisting. In this way the hole cannot fail to be circular and quite perpendicular. By this means, at the well of the Military School, they have got down a single tube of iron plates, rivetted, of 11 inches diameter, to the depth of 650 feet. The tube moves freely—one man can turn it round. The wire rope would answer well for this mode of boring. The moutons are not difficult to make; a village blacksmith may construct or repair them; he should fasten the steel chisels in such a way that they can be occasionally taken out to be sharpened. The method of boring by means of the rope is much used in Saxony.—*Mining Journal.*

BUILDERS' BENEVOLENT INSTITUTION.

In another part of the Journal, it will be seen that we have requested the attention of our engineering readers to the merits of an institution for the relief of engineering workmen, and now we have to make a similar request of our architectural readers. They will see that a meeting has been held for the purpose of establishing a Builder's Benevolent Institution, and we hope that they will readily lend their aid for the promotion of an object so laudable. We need scarcely say that it has our very best wishes for its success. The meeting to establish an asylum and pension fund, and for the general relief of the decayed and suffering members of the builders' trade, was held on the 24th ult. at the Crown and Anchor, Strand; Mr. Burnard, surveyor, in the chair. The advertisement convening the meeting having been read by Mr. Barber, the secretary, the chairman, in a brief but neat speech, detailed the objects of the institution, remarking that there were no less than 20 trades connected with the building business—as architects, surveyors, painters, engineers, bricklayers, slaters, sawyers, &c.; yet the builders had neither an institution like that which they were assembled to establish, nor an asylum, nor any benefit society to apply to in poverty or old age. The objects for which the institution was about to be formed were highly praiseworthy and beneficial, and he was glad to say, that the committee had been promised support in all cases in which they had applied, and he hoped soon to see the builder's asylum rise second to none even in this great metropolis. The secretary then read letters from the Marquis of Westminster, the Earl of Cadogan, Sir R. Peel, Mr. Barry, the architect, Mr. Philip Hardwicke, Mr. D. Burton, Mr. Thomas Cubitt, Alderman John Johnson, and many other gentlemen of standing and respectability, all concurring in the objects of the meeting. The report of the committee was then read. It contained a well-written narrative of the steps the committee had taken, the reception they had met with from those to whom applications had been made to assist them in their praiseworthy endeavours to found the Builders' Asylum, and concluded with a very flattering account of the success that had attended their efforts. The report being adopted, a series of resolutions was put and passed in the usual manner. A subscription was entered into before the members left the room, for carrying out the purposes of the institution, and was liberally responded to.

REPAIRING AND MAINTAINING OF PUBLIC WORKS.

The following important judgment in the case of *The Queen* v. *The Bristol Dock Company*, was delivered in the Court of Queen's Bench, Westminster May 25, at the sittings *in Banco*. The defendants in this case have been incorporated under the 43rd George III., c. 140, for the purpose of making, completing, and maintaining a new watercourse in connexion with the river Avon, and this purpose they had effected. Some part of the works of the new watercourse, however, became subsequently out of repair; and upon a former occasion a rule had been obtained calling upon them to show cause why a *mandamus* should not issue commanding them to repair that portion of the banks of the new watercourse which had become dilapidated, and which, in its present condition, caused an obstruction to the navigation. The rule was made absolute, and the writ having issued, the defendants returned that they were not bound, according to the general law of the land, or to the provisions of the particular act above mentioned, to repair the portions of the watercourse which formed the subject of the discussion.

Lord Denman now delivered the judgment of the court upon the case, which was, that in the circumstances of the transaction the defendants were bound to make the repairs which the writ commanded them to make. His lordship laid it down in the course of the judgment, that where parties obtained an act of parliament for the construction and maintenance of great public works, they were bound in law to fulfil all the incidental duties of which the performance was necessary for the discharge of their duties in respect to the principal subject. His lordship also stated, that if public bodies omitted the performance of such incidental duties, they would be compelled to do so by the direct interposition of this court. It had been argued upon the part of the defendants, that as the injury consequent upon their neglect to repair the bank was of a public nature, and one for which they were liable to an indictment, that particular proceeding ought to be adopted, and there was therefore no necessity and no ground for a *mandamus*. The court, however, dissented from this position, and declared that where a company were obliged to do a particular work, and where the consequence of their not doing it was to produce a public nuisance, that circumstance, although it rendered them liable to an indictment, did not release them from the necessity of a specific performance of their duty upon the subject, in obedience to the mandate of this court. In this case, therefore, a peremptory *mandamus* would be awarded.

S. L. IN REPLY TO CANDIDUS.

Sir—I am surprised that Candidus should have thought it necessary to combat an imaginary assertion by such very trite observations. But he is evidently affected with the usual mania of critics, viz., that of putting an arbitrary interpretation on the object of their criticism, and then attacking the author for entertaining an idea which is but the fruit of their own fertile imagination. For instance, where Candidus can find that I have said any thing to discourage the roughest handling of public men, if kept within the bounds of truth and reason, I cannot possibly conceive; nor can I find any thing which can justify his supposition, that I may probably greatly prefer Buckingham Palace to Windsor Castle, &c.

With regard to mullioned windows, I confess I cannot see the propriety of substituting any thing which would have the effect of an open screen, for a glazed window; and though we may make infinitely greater departure from the genius of Grecian architecture. Candidus may remember that pure Grecian was not the style advocated; the architect must go to Rome and Pompeii for his materials, as well as to Athens.

When I spoke of the difficulty of persuading persons to adopt Gothic, who are not possessed of antiquarian taste, I said nothing about "soi-disant" or "hole-in-the-wall" Gothic; every one is aware of the great facility afforded for the adoption of that style—I mean by Gothic such as would do credit to an architect; but most persons find this to interfere too much with their comfort for them to "allow it to be properly treated."

With respect to what Candidus is pleased to call my very bold assertion, I would beg him to observe that I stated that the *object* of the architect, when he employed the Grecian or Roman style, was invention, not that originality was always the *result* of his efforts. I shall, however, be glad if he will refer me to a modern Gothic building possessing half as much originality as St. Stephens, Walbrook, or the spire of Bow church.

I quite agree with Candidus that it is well to avoid "squeamishness and affected delicacy in architectural criticism," but it would also be well if he would pay some respect to decency in the choice of his expressions, and not make use of those of which a gentleman would be ashamed, and which diminish, rather than increase, the force of his observations.

I remain, &c.,

S. L.

STEAM NAVIGATION.

THE MONGIBELLO STEAM SHIP.

This fine vessel belonging to the Neapolitan Steam Navigation Company at Naples, is fitted with a pair of Messrs. Maudslay, Sons and Field's patent double cylinder engines, of the nominal power of 200 horses; their general principle is described in the last volume of the Journal, page 73.

The improvements realized in this description of engine are *first*, that the power is applied more directly to the cranks than in any other construction, having only two working joints through which the power is conveyed, viz. the lower and upper ends of the connecting rod, the stroke being of the usual length, and the connecting rod of the usual proportions; the force of the engine is also so completely confined within its own framing, that no strain is thrown upon the vessel. The *second* advantage is that the space occupied by the engine, is not greater than in an engine of half the power, on the side beam construction, and when combined with their improved boilers, (as is the case on board the Mongibello), the total length occupied by the machinery is reduced to 40 feet, whereas the ordinary construction requires 60 feet, thus effecting a saving of one-third, on this most important head. The *third* advantage arises from the reduction in weight, which in the Mongibello, and including water in the boilers, was 150 tons, being 13½ cwt. per horse power, instead of one ton per horse power, which is the weight in beam engines, and even this is often much exceeded.

These advantages, which bear so strictly upon the profitable employment of steam vessels, are fully realized in the one in question, which is of 500 tons burthen, being 156 feet long, and 26 feet beam; besides the saving in space referred to above, the machinery of the Mongibello is about 70 ton lighter than ordinary beam engines, and in addition to the increased tonnage derived from the saving in space. She thus possesses 70 tons additional buoyancy for cargo, or coal, for a more extended voyage. Another consideration, which ought not to be overlooked, is that in building a vessel to carry a certain number of passengers, or quantity of cargo, the first cost of the vessel may be much reduced; the same space for passengers and tonnage for goods, may be obtained by a vessel of 70 tons less measurement, and the saving under this head cannot be estimated at less than 1400*l.* in a vessel of the size of the Mongibello, and it would be greater as the size increased.

These engines work with great steadiness and effect, making 25 strokes per minute, and performing from 11½ to 12 miles per hour. They are fitted with expansion gear, brine pumps, &c. In short the vessel is replete with every requisite for a sea-going ship.

RENNIE'S TRAPEZIUM PADDLE WHEEL.

In our number for March last, we enumerated some of the advantages which were likely to be derived from the adoption of the above invention in steam navigation; we have now the satisfaction to lay before our readers the results of a series of experiments which have been made on the efficacy of the Trapezium Paddle Wheels, in comparison with the common Rectangular Paddle Wheels. The Lords of the Admiralty having decided that the trial should be made upon a vessel of known qualities, fixed upon the African, an old gun brig which had been converted into a steamer, by two engines of 45 horse power put into her, as best calculated to give a comparative result. Accordingly the old paddles were removed, and a pair of trapezium wheels fixed in on the same shaft, which formerly served for the old wheels, so that with the exception of a slight alteration in the paddle boxes, no further additions were required. On the 14th of April last the whole being ready, the engines were set to work, and the vessel proceeded down the river to the measured mile in Long Reach.

The dimensions of the African are—length, 109 ft. 10 in. midship section; breadth, 24 ft. 10 in. semi-elliptical, bluff at the bows; depth, 12 feet full at the quarters. She is a good sea boat, but not calculated for high velocities, as compared with steam vessels of modern times.

The power of the engines is two of 45 horse power each, the number of strokes 29 to 30.

The velocity of the vessel at a load draught of 9 ft. 5 in. is nine miles per hour through still water.

According to a series of experiments made with the African by Mr. Kingston, Admiralty engineer, the diameter of the old wheel was 14 ft. 7 in., the width 7 feet, the area of the floats immersed was about 62 feet super., the mean draught of the vessel was 9 ft. 4½ in., and with the barometer at 26¾ inches, and the engines making from 29 to 30 strokes per minute, the maximum mean velocity opposite the measured mile was 9·174 miles per hour.

	miles per hour.
On the 14th of April last, the engines making from 22 to 23½ strokes	8·29 to 8·75
On the 26th April, 23 strokes	8·4 to 8·6
On the 1st of May, 25 to 28½ strokes	8·8 to 9·032
On the 8th of May, 25 strokes	8·6 to 8·8
On the 12th of May, 26 to 27½	8·5 to 9·136

The last results were obtained with from 2½ strokes of the engines less than formerly, and with a reduced diameter of wheel of 22 inches, and an immersed surface of 30 square feet. The action of the float in the water was entirely free from shocks or vibration; thus establishing on a greater scale than hitherto, the properties of the trapezium wheel as promulgated in the prospectus, namely, that it combines all the advantages of the common paddle wheel, and does away with all its defects, arising as before stated, from the great weight, width, and indirect action of the former, and combining all and even greater simplicity of the latter.

The Steam Frigate "Styx."—On the 6th of May an experimental trip was made with this vessel down the river as far as Gravesend. There was present a numerous party of naval and scientific gentlemen, among whom were Lord Prudhoe, Admiral Sir Philip Durham, Sir W. Symonds, Chevalier Benkhausen, the Russian Consul General, Mr. Routh, &c. She is what is termed a second class government steam frigate, and the third vessel of that class fitted within the last six months. Altogether there will be five vessels, viz., The "Driver," "Vixen," "Styx," "Growler," and "Geiser," the two latter are not yet finished; they are all built to one mould, under the direction of Sir William Symonds, and to be fitted with engines by Messrs. J. & S. Seaward & Capel. The dimensions of the "Styx" are, length 210 feet over all, or 186 feet between perpendiculars, 36 feet breadth of beam, and 21 feet depth of hold; she draws 13 feet aft and 12 feet forward, and when laden with her full complement of guns, stores, &c., 15 feet aft and 14 ft. 6 in. forward. She is to carry four 8 inch guns, for 64 lb. hollow shot, and two 10 inch guns on swivels and slide beds for 96 lb. hollow shot. The two engines are of the collective power of 560 horse power; the cylinders are 62 inches diameter, and 5 ft. 3 in. stroke, performing 17 strokes per minute; the paddle-wheel is 26 feet external diameter, breadth of float boards 8 ft 3 in, divided into two, each being 11 inches wide. The engines are upon Messrs. Seaward's patent principle, the action being applied direct from the piston rod to the crank of the paddle shaft, as adopted on board the "Cyclops." Drawings and a description of these engines will be found in the Journal for February last. Mr. Samuel Seaward has also applied his patent for disconnecting the paddle wheels, which is extremely simple and efficacious; it only required 3 minutes to disconnect one of the wheels, and 4 minutes to reconnect it, and we have no doubt if the men had had a little more experience, they could have been connected and disconnected in half that time. The engines worked very beautifully, and free from the slightest vibration; the speed through still water was at the rate of about 10½ miles per hour. During the excursion the company were entertained with a sumptuous collation.

Blackwall Steamers.—The Blackwall Railway Company have had three iron steamers built by Messrs. Ditchburn and Mair, to run from the Brunswick Pier to Gravesend, viz. the "Brunswick," "Railway," and "Blackwall," all of one mould. Their length is 146 feet and 19 ft. beam. The mould is beautiful, the bows being remarkably sharp, and throwing but little, if any, wave in front; the cabins are tastefully finished, and do credit to the builders. Each vessel is fitted with engines of 90 horse power collectively, and all have tubular boilers. The *Brunswick* has a pair of oscillating engines by Messrs. J. & S. Seaward & Capel, and the same description of engines are on board the *Railway* fitted by Messrs. John Penn & Son. We were present at an experimental trip of this boat on Saturday the 8th ult., when her speed exceeded that of any other boat on the river; indeed her average is about 16 miles per hour. Her performance gave great satisfaction to the Directors of the Railway who were on board, and to the company generally. The whole of the machinery including the boilers is only 45¾ tons in weight, very little more than one half the usual weight of engines of so large a power. The other vessel, the "*Blackwall*," has a single steeple engine of 90 horse power fitted with tubular boilers by Messrs. Miller, Ravenhill & Co. We understand that the speed of this vessel is nearly equal to that of the "*Railway*."

The Elberfelt.—This splendid vessel built of iron by Messrs. Ditchburn and Mair, for navigating the Rhine, performed an experiment trip on the Thames on the 8th instant. Her dimensions are, length 176 feet, beam 21 feet, depth 11 ft. 6 in., and draws only 2 ft. 8 in. of water. her cabins are fitted up with great taste, particularly the ladies cabin, and the saloon which is decorated with views on the Thames,—throughout the vessel every attention has been paid to the comforts of the traveller. She is propelled by a pair of oscillating engines of 55 horse power each, by Messrs. Miller, Ravenhill and Co., her speed in still water is calculated at 13 miles per hour; the boilers are tubular, of Mr. Spiller's patent.

Steam Frigates.—The town of Greenock exhibits at present a scene of no common interest. Six large steam frigates are now being constructed in the town or its vicinity, each of these of about 1,500 tons capacity, and carrying engines of 500 horse power, being part of the fleet of 14 armed frigates destined in time of peace to carry out and distribute the mails among our West Indian colonies. Four of these are to be supplied by a single firm in Greenock, who deliver the ships, engines, and equipments complete, and ready for sea. We announced a short time ago the successful launch of the first of these four, the Clyde, which was constructed by the late Mr. Duncan. The second of these ships, the Tweed, was launched from the yard of Messrs. Thompson and Spiers on Saturday last, and we hope soon to announce the completion of the series of these four sister ships, in the launch of the Tay and the Teviot, which are rapidly progressing on the stocks. In general appearance and construction this ship resembles closely her precursor, the Clyde, being slightly fuller forward, and finer abaft. To the eye she also seems larger than the Clyde, but this may arise from the latter being a foot or two deeper in the water, having already her whole engines and boilers fitted up on board, although it is only about two months since her launch. The dimensions of the Tweed are as follow:—Length, over all, 240 feet; keel and forerake, 215; beam, 37; depth, 30.—*Greenock paper.*

Thames Steamers.—The competition among the steamers has become so great, and their numbers have so much increased of late, that 17 vessels are daily engaged in conveying passengers between Gravesend and London. Some of them charge 2*s.* in the after cabin, and 1*s.* 6*d.* in the fore part of the steamer, for each passenger; others 1*s.* 6*d.* and 1*s.*, and a few 1*s.* only all over the vessel; while the steamers from Blackwall to Gravesend convey passengers for 8*d.* each. Fourteen steam vessels are engaged in carrying passengers between London and Greenwich, and a majority of them have lately reduced their fares to 6*d.* each; but the pier dues swallow up one-third of the fare, and it is doubtful whether the steam boat companies will be able to continue the reduced fares for any length of time. Eight steamers are constantly running to and from Woolwich, and they will receive a great accession in a few days by the fast and elegant boats of the Watermens' Steam-packet Company. There are 16 small vessels belonging to different companies steaming away from morn till night above bridge, and on Sunday last they carried upwards of 55,000 passengers, at 4*d.* per head, between the numerous piers from London-bridge to Chelsea.—*Times.*

Improvement in the Construction of Steam Ships.—A Correspondent of the *Times* suggests that safety bulkheads, by which a vessel is divided into three or four water-tight compartments, should be introduced into ocean steamers in future. The suggestion is an excellent one, but it ought to be enforced by legislative authority, and applied to all steamers. Many lives and much valuable property would have been saved if such a regulation had been in force since steam navigation has been so largely extended. The loss of the Phœnix, which was struck before the paddle-box by another large steamer at sea, affords one instance; and the Albion, on her voyage from Dublin to Bristol, touched a sunken rock on the Welch coast, and immediately went down in comparatively smooth water, and on a beautiful day, in consequence of the leak produced in her bow. The distressing loss of the Killarney, on the coast of Cork, would, no doubt, have been averted, had not the fires in the engine-room been extinguished by a leak, which it was impossible to keep down. Many other cases might be cited; and we shall place in juxtaposition with the preceding an accident which happened to the Royal William a celebrated steamer belonging to the City of Dublin Company, on one of her voyages from London to Dublin. This vessel, we must premise, like several others belonging to the same spirited company, is divided into water-tight compartments by bulkheads. One dark stormy night, when off the Isle of Wight, she suddenly came into violent collision with a three-masted ship, which exhibited no lights; and a large hole was made in her bow, which must, had she been built like ordinary steamers, have involved her almost instantly in the same fate as the Albion. The bulkhead, however, near her bow, prevented the leak from spreading—nay, so little inconvenience did this alarming collision occasion, that she proceeded on her voyage to Plymouth, scarcely depressed in the slightest degree, to use nautical language, "by the head." This is a striking anecdote; and we only wonder that steam-boat proprietors have not long ago seen the importance, even for their own interest, of adopting the mode of construction which saved the Royal William. We repeat that that they ought to be compelled to do so; and we trust that some member of Parliament will bring the subject forward without delay. We are not able to say whether some such safeguard might or might not be adopted in ships; but the recent frightful loss of life occasioned by the sinking of the Governor Fenner, owing to a collision with a steamer, ought at all events to draw attention to the subject. In the Thames 1,000 or 1,200 persons often trust themselves in a single steamer of comparatively slight construction.—*Glocestershire Chronicle.*

Launch of a Steam Frigate.—The West India Royal Mail Steam-packet Company's magnificent and powerful steam ship the Forth was launched from the building-yard of Messrs. Robert Menzies and Sons, Leith, on Saturday last. She glided into the Forth, the estuary after which she has been called, in a most majestic manner, and in presence, it is reported, of not fewer than 80,000 spectators. So gay a scene had not been witnessed in Leith since the visit of his late Majesty George IV., in August, 1822. The following are the dimensions of the Forth:—Length of keel, 215 feet; on the spar deck, 229 feet; over all, 245 feet: breadth over paddle-boxes, 60 feet; depth of hold, 30 feet 3 inches; tonnage, 1,940. She is to be propelled by two engines now fitting at Liverpool by Mr. Bury, of 220 horse-power each. The Forth is the third steam frigate already launched for the West India Royal Mail Steam-packet Company. The two first were built on the banks of the Clyde.

Steam-ship Building in Derry.—In Mr. Coppin's yard there has been laid the keel of a vessel intended for foreign trade, which, in point of dimensions, will come very little short of the largest steamers ever built, the proprietors of her being partly Englishmen. She is to be impelled by the Archimedean screw, to have a horse-power of between 500 and 600, and to be of 1,500 tons register. Her keel is 221 feet, only a few feet inferior to that of the greatest steamer launched, and her length over all will be 230 feet.—*Derry Journal.*

MISCELLANEA.

Westminster Bridge is again opened to traffic, after having, during the short period of four weeks, been subjected to extensive repairs. The well-known hollow arch has been removed, and spandrel walls with longitudinal arches in brickwork have been substituted, so as not only to strengthen the pier, but to remove a serious cause of danger, threatened by the pressure of the hollow arch on the haunches of the adjoining main arches. A rather unusual circumstance has been the removal and restoration of a whole course of stone throughout one arch. Great satisfaction has been given by the prompt and energetic manner in which the alterations have been effected by Mr. Cubitt, under the directions of the engineers, Messrs. Walker & Burgess.

Preston and Wyre Railway, Harbour and Dock Company.—Extract from a report to the directors by Captain Denham, at the last half-yearly meeting of the proprietors.—"The new channel through the 'Knot-spit,' and over the 'Little Ford,' has been so deepened as now to afford 13 feet of water at half tide through the straight course thus produced upon the line of lights direct from sea into the harbour. The present period is occupied in dredging up the shelving bottom between the landing wharf and 'Canshe-hole' anchorage, so as to produce a continuous depth of 12 feet at low water spring tides, an object we hope to attain by June next, during which the upper layer of shelving shore now interrupting the north or early approach to the wharf, will be excavated, leaving the under or lower shelf to be dredged down to 12 feet over the whole space across to 'Canshe-hole.' The dredge's service this year will thus be wholly dedicated to the wharf frontage and approaches. The new Channel to Sea will, however, be improved by excavating and carrying away at low water the remainder of the 'Knot-spit,' and trimming down the surface and marginal projections of the new cut or channel, the marl arising from which will be appropriated to the 'neckings' half tide wier about to be constructed on the opposite side of the channel. This latter work will also be prosecuted this year, and additional pontoons and stone flats are preparing for it. This tide wier will have the effect of concentrating the whole volume of back water, the scouring force of which has already been so essentially increased by the completion of the 'Knot-gulph' embankment."

Florence and Leghorn Railway.—A supplement to the *Florence Gazette* of the 27th April, contains the decree of H. I. and R. Highness, the Grand Duke of Tuscany, granting for the term of 100 years (to be reckoned from the time when it will be completed and opened to the public), the railway from Florence to Leghorn, to the Company announced by the Manifest of Fenzi and Senn of the 24th April, 1838, to be executed according to the report of the celebrated English engineer, Robert Stephenson, Esq. His Imperial and Royal Highness graciously allows said railway to bear his royal name of "Leopold," and grants numerous advantages and privileges, among others *the importation duty free, of all the iron works, machinery, locomotives, and every other article required for its construction, and completely placing it in active operation.* The exemption from the register stamp due on all the deeds of the company during the construction of the railway, the option of converting into perpetual leaseholds the amount of such lands as will be occupied by the company, and which may belong to the state, or to religious corporations, and which from its nature should be subject to re-investment. The right of expropriation fixed on a liberal basis, with the right of immediate occupation, and a low tariff for the transport of persons and goods.

Copper Mine.—The copper mine recently discovered in Jamaica is situate in Mount Vernon, a huge mountain six miles to the East of Kingston. The lodes run from east to west, with a dip to the north. The veins of ore are found in the neighbourhood of Lucky Valley estate, in the parish of Port Royal, and at the base of the mountain. The richest ore is a sulphurte, yielding 40 per cent. of metal. This ore is obtained in immense quantities from a shaft which opens on a small stream sufficient to carry away the debris. Several hundredweights have been sent to London and Swansea for smelting, great difficulty having been experienced in performing this operation perfectly in Jamaica, from the want of reverberatory furnaces. There is also a carbonate which yields 11 per cent. of metal by the humid process. This is a very beautiful ore, and occurs in what is called abon rock. The matrix consists principally of lime-stone, argillaceous sand-stone, slate, schist, and a fine black sand-stone. The black sulphuret, which is abundant, is obtained in masses resembling wet and rotten coals, soft when extracted from the mine, but hardens in the sun, and is full of pyrites. When dry it is perfectly friable. The situation of the mine is convenient, being only three miles and a half from the sea, and the road is a gradual descent to the harbour, Bull Bay, where there is good anchorage for vessels. It may be added that the mine is in full operation, a company having been formed, and all the shares bought up. When the packet left Jamaica, Senor Don Rennaldo, the captain of the Cuban mines, had been applied to for assistance and advice, and was daily expected there.

Consumption of Smoke.—We have great pleasure in directing public attention to the efficacy of Hall's apparatus for the consumption of smoke from steam engine chimnies. Mr. Hall has just completed one at the manufactory of Messrs. Boden and Morley, in Castle-street, in this Borough, which from its efficacy, if generally adopted, will leave no cause of complaint from what has hitherto been a source of annoyance to the inhabitants of the borough. The furnace is supplied by a current of air heated by the furnace itself, which, when in full operation, completely consumes the volume of dense smoke, which is frequently sent forth from the chimney of a steam-engine. Of course this cannot be done till the fire is got up in the morning, and whenever the furnace door is opened for feeding, the apparatus ceases to act; but half a minute suffices to clear the chimney, when the furnace door is shut, and then, however thick and dark the smoke was previously, the quantity is immediately greatly reduced and its density gives place to a silvery hue. We believe the apparatus saves something considerable in fuel, and we are sure its adoption will be hailed with general approbation by the inhabitants of this borough.—*Derby Reporter.*—A short time ago, our columns contained a notice of the perfect consumption of smoke by apparatus applied to the steam engine of Messrs. Benjamin Cort and Co., of this town; it has also been used with equal success as applied to other steam engines, both here and at Derby. We are highly gratified at being informed that this invention answers equally well with locomotive engines. A trial was made of it, as attached to the "Wizard," a few days ago, on the Midland Counties Railway, in the presence of some of the directors of the company, and of several other gentlemen; of the former were William Hannay, Esq., and Henry Youle, Esq., and of the latter were Francis Wright, Esq., of Lenton Hall, H. B. Campbell, Esq., &c., who all expressed their high approbation of its satisfactory operation. The above apparatus for which a patent was taken out in January last, is the invention of Mr. Samuel Hall, the inventor of the condensers (known under his name), for supplying pure distilled water instead of salt or otherwise impure water to the boilers of marine and other steam engines, as well as the inventor of the reefing paddle wheel for steam vessels. The importance to railway companies of being able to use coal instead of the costly article of coke to locomotive engines, can scarcely be estimated, so greatly must it reduce the expense of the transit of passengers and goods, and consequently increase the profits of the shareholders.—*Nottingham Review.*

Dorsetshire—The body of the church of St. Mary's, Wareham, Dorset, is now being pulled down for the purpose of being rebuilt. This part has evidently been already once before pulled down and rebuilt, the nave being divided from the side aisles by square massive piers of rough rubble construction, with impost and archivolt mouldings of a Roman character. This alteration was possibly done towards the latter end of the 17th, or beginning of the 18th century. The workmen have found in the walls some fragments of stone with curious carvings and inscriptions. There is a fine tower and spacious chancel of decorated Gothic which will not be touched, and attached is a small sepulchral chapel with tombs of cross legged knights in chain armour. The new church provides accommodation for 1000 persons. The contract has been taken by Messrs. Cornick and Son, of Bridport, Dorset, and the works are to be completed by Michaelmas 1842, under the superintendence of Mr. T. L. Donaldson, architect, by whom also a new Scotch Church is to be erected at Woolwich, in the Norman style, with accommodation for 1000 persons, half of whom will be soldiers of the garrison. The plot of ground for the church and schools, which are to be erected in connexion, has been given by the Government, in consideration of the sittings, which will be provided for the troops of the Kirk communion.

Mr. Stephenson's Lime Works at Amber Gate.—Mr. Stephenson has now commenced burning lime at these works, and is sending it to the different places adjacent to the North Midland Railway. In the course of a short time it will be conveyed to most of the principal towns in England. The kilns are built in a handsome and substantial form, standing from 30 to 40 feet above the surface of the ground. The limestone is procured from the village of Crich, about two or three miles distant from the kilns, on a tramway formed for that purpose. A short distance from Crich, the tramway passes through a tunnel between 50 and 60 yards in length; a little further on is an inclined plane, worked by a wheel, which lets down six wagons full of limestone, and draws up the same number of empty wagons. Nearly adjoining this is another inclined plane, which is uncommonly steep, rising at the rapid rate of one yard in three and a half, and is worked by a large drum, round which passes a wire-rope; a lever is attached to the drum, by which one man alone is able to regulate the speed of the wagons at pleasure, or stop them altogether. Two full wagons are let down and two empty ones are drawn up at the same time. The full wagons pass over the Cromford canal by a wooden bridge (elevated several feet above the surface of the water) to the top of the kilns. These stupendous works, when finished, will be of the most extensive character in England, or we may say in the whole world. They will, when complete, be able to turn out upwards of 200 tons of lime per day.—*Sheffield Patriot.*

Victoria Park Bill.—The Bill authorising the Woods and Forest to form a Park in the eastern part of the metropolis, has already past the House of Commons.

The bronze statue of Rubens is at length completed, and has been sent from Liége to Antwerp, the place of its destination.

Parisian Bitumen.—The terraces at the Slough station of the Great Western Railway are being lined with this material, its use has of late been considerably on the increase: it has been introduced in several parts of the metropolis.

LITERARY NOTICES.

Mr. Dollman has given the public two faithful representations of the restorations of the Vicar's Close at Wells, the details of which are given in Mr. Walker's book. The chimneys we think felicitous, but the sentry-box porches might, we conceive, without injury have been omitted by the architect; fidelity of this kind savours too much of the ingenuousness of the Chinese tailor, who treated the patches in the pattern coat as an essential part of the workmanship.

Mr. E. Clifford, a teacher of mathematics, has brought out a small treatise styled *Arithmetic Considerations on Marquoi's Parallel Scales, and the Protractor,* which contains a number of useful calculations and directions.

LIST OF NEW PATENTS.

GRANTED IN ENGLAND FROM 29TH APRIL, TO 27TH MAY, 1841.

Six Months allowed for Enrolment.

James Sims, of Redruth, Cornwall, civil engineer, for "*certain improvements in steam engines.*"—April 29.

Alfred Jeffery, of Prospect-place, New Hampton, Middlesex, gentleman, for "*a new method of defending the sheathing of ships and of protecting their sides and bottoms.*"—April 29.

George Townshend, of Sorpcote-fields, Leicester, Esquire, for "*improvements in machinery or apparatus for cutting certain vegetable substances.*"—April 29.

Joseph Gibbs, of Kennington, civil engineer, for "*a new combination of materials for making bricks, tiles, pottery, and other useful articles, and a machine or machinery for making the same, and also a new mode or process of burning the same, which machine or machinery and mode or process of burning are also applicable to the making and burning of other descriptions of bricks, tiles, and pottery.*"—April 29.

Miles Berry, of Chancery-lane, for "*certain improvements in machinery or apparatus for making or manufacturing nails and brads.*" (A communication.)—May 4.

Francis Joseph Massey, of Chadwell-street, Middleton-square, watch manufacturer, for "*improvements in the method of winding up watches and other time keepers.*"—May 4.

Edward Newton, of Leicester, manufacturer, and Thomas Archbold, of the same place, machinist, for "*improvements in producing ornamental or tambour work in the manufacture of gloves.*"—May 4.

Charles Thomas Holcombe, of Bankside, Southwark, iron merchant, for "*certain lubricating or preserving matters for wheels and axles, applicable also to the bearings, journals, or other parts of machinery.*"—May 4.

Hugh Graham, of Bridport-place, Hoxton, artisan, for "*an improved manufacture of that kind of carpeting, usually denominated Kidderminster carpetting.*"—May 6.

Moses Poole, of Lincoln's Inn, Esquire, for "*improvements in the manufacture of fabrics by felting.*" (A communication.)—May 6.

Philemon Augustine Morley, of Birmingham, manufacturer, for "*certain improvements in the manufacture of sugar moulds, dish covers, and other articles of similar manufacture.*"—May 6.

James Hancock, of Sidney-square, Mile End, civil engineer, for "*certain improvements in the manufacture of locks, keys, latches, and other fastenings, part of which improvements are applicable to taps and cocks for drawing off fluids.*"—May 6.

John Paley, jun., of Preston, Lancashire, manufacturer, for "*certain improvements in looms for weaving.*"—May 10.

Hooton Deverill, of Nottingham, lace manufacturer, for "*certain improvements in machinery for making and ornamenting lace, commonly called bobbin net lace,*"—May 10.

Andrew Mc Nab, of Paisley, North Britain, engineer, for "*certain improvements in the manufacture of bricks.*"—May 11.

Edmund Taylor, of King William-street, gentleman, for "*certain improvements in the construction of carriages used on railroads.*" (A communication.)—May 11.

Henry Pinkus, of Maddox-street, Hanover-square, for "*an improved method or methods of applying electrical currents or electricity, either frictional, atmospheric, voltaic, or electro magnetic.*"—May 14.

James Gregory, coal master, and William Green, turner, both of West Bromwich, Stafford, for "*certain improvements in the manufacture of iron and steel.*"—May 14.

Pierre Journet, of Dean-street, Soho, engineer, for "*improvements in fire-escapes, which improvements are applicable to other useful purposes.*"—May 19.

John Carr, junior, of Paddington, engineer, for "*improvements in apparatus for retarding and stopping railway-carriages.*"—May 20.

Charles Phillips, of Chipping Norton, Oxford, engineer, for "*improvements in reaping and cutting vegetable substances as food for cattle.*"—May 20.

Joseph Woods, of Lawn-place, Lambeth, Surrey, civil engineer, for "*certain improvements in locomotive engines, and also for certain improvements in the machinery for the production of rotatory motion for obtaining mechanical power, which improvements in machinery are also applicable for raising or impelling fluids.*"—May 22.

William Gall, of Beresford-terrace, Surrey, for "*certain improvements in the construction of inkstands.*" (A communication.)—May 22.

John Ainslie, farmer, Redheugh, North Britain, for "*a new and improved mode of making or moulding tiles, bricks, retorts, and such like work from clay, and other plastic substances.*"—May 22; four months.

Christopher Dumont, of Mark-lane, London, for "*improvements in the manufacture of metallic letters, figures, and other devices.*" (A communication.)—May 22.

John Winterborn, of Clarence-place, Hackney-road, surgeon, for "*improvements in machinery to facilitate the removal of persons and property from premises, in cases of fire; which improvements are applicable to raising and lowering weights generally, to assist servants cleaning windows, and as a substitute for scaffolding.*"—May 22.

William Lewis Rham, of Winkfield, Berks, clerk, for "*certain improvements in machinery or apparatus for preparing land, and sowing or depositing grain, seeds, and manure.*"—May 22.

John Whitehouse, of Deptford, engineer, for "*an improved method of making boilers, to be used in marine steam engines.*"—May 22.

William Joest, of Ludgate-hill, merchant, for "*improvements in propelling vessels.*" (A communication.)—May 26.

George Hulme, of Saint John-street, Smithfield, cock founder, for "*improvements in water closets.*"—May 27.

Joseph Bettridge, of Birmingham, wood turner, for "*an improved method of manufacturing papier mache, pearl, china, ivory, horn, wood, and composition, into pillars and stands for table and other lamps, and other articles of domestic furniture.*"—May 27.

James Shanks, of Saint Helen's, Lancashire, chemist, for "*improvements in the manufacture of carbonate of soda.*"—May 27.

TO CORRESPONDENTS.

Communications from M.R., Daniel Clark, *&c., received too late will appear next month.*

We have received a proposition for forming "An Association of Architectural and Engineering Draughtsmen," which we have deferred for consideration until next month.

Communications are requested to be addressed to "The Editor of the Civil Engineer, and Architect's Journal," *No.* 11, *Parliament Street, Westminster.*

Books for Review must be sent early in the month, communications on or before the 20th (if with drawings, earlier), and advertisements on or before the 25th instant.

Vols. I, II, and III, may be had, bound in cloth, price £1 each Volume.

ERRATA.

In last month's Journal, p. 173, for *Harry* Austin read *Henry* Austin.

P. 129, for Mr. Edward Hall (late of *Birmingham*) read late of *Manchester.*

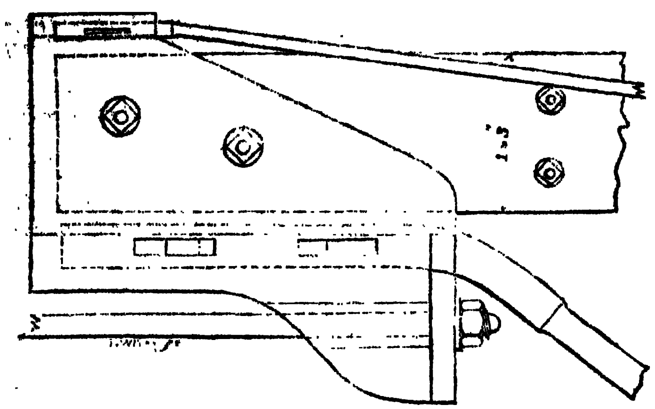
The type of pages 151 and 152, after it was made up, got disarranged; we have consequently reprinted them, which are given with the present number. We have to request our readers to cancel those pages, and substitute those given herewith.

NEW FORM OF VIADUCT.

Plate VII.

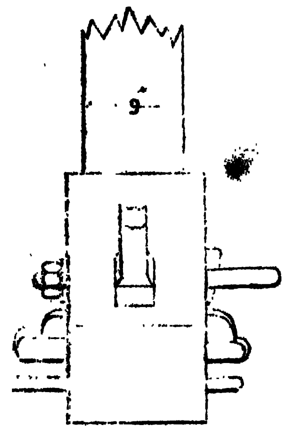
The accompanying drawings show a new species of viaduct that has been made use of as a general design, in the parliamentary estimate of a recently surve

Fig. 4—Side view of the Clutch Box D.



The principle in its simple form, is not new to the engineering world, having been put into execution in the "Foot bridge over the Whitadder, at Abbey St. Bathans," (see Theory, Practice, and Architecture of Bridges, part four,) and being commonly used in temporary erections, scaffolding, &c., and frequently applied in strengthening various kinds of vehicles. The novelty consists in carrying out the idea to the magnitude of the present case.

Fig. 5—End view of the Clutch Box C.

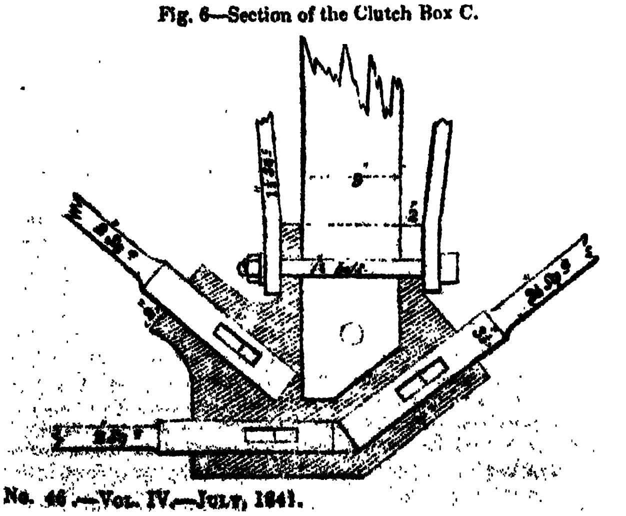


It will be seen that the system is applicable on a great scale, in those cases only where there is a large amount of headway to spare, as the efficiency of the arrangement is so completely dependant on the inclination of the tension bars. The estimation of the strength in the original form, is a matter of great ease, involving only a simple case of resolution of forces.

This design is made for a single line of rails only, but it would appear that it might be much more advantageously and economically applied to a double line.

A reference to the drawing will preclude the necessity of any detailed description, and it will be necessary merely to draw attention to the more important points. It will be seen that the application of the tension bars is not confined to the resistance to vertical deflection, but that it is made use of in giving lateral strength to the main supports, (inverted tressels would perhaps be the most descriptive term), their bending being prevented in one direction by the transverse studs and tie-bolts, and in the other by the f the iron rods.

Fig. 6—Section of the Clutch Box C.



A weight entering upon the bridge will be perceived to immediately distribute its effects over the whole structure, by means of the ascending intermediate bars; these bars will effectually prevent any partial deflection that might be expected to occur upon an unequal distribution of the load.

It will be observed that rods are dotted in, and noted as being carried to the sides of the piers, to prevent any lateral oscillation; little fear of this however need be entertained, as the surface exposed to the wind would be so slight; nevertheless if there were any apprehension of such an effect, it might be further guarded against, by a divergence, of the sides of the supports, as shown by the dotted lines at D′, D′, on the transverse section; and this would be done with very little diminution of strength. In a double line there would be no need of such precaution.

The estimated cost, including scaffolding, &c., and exclusive of piers, is 6*l.* per lineal foot; the quantities I took out myself, and can bear testimony to their fulness; the prices were given by another, and were high in consequence of the difficulty of the localities; in short I believe that the above price is rather more than would be the cost in average cases. With regard to the strength, I think it will be found by any one who will be at the trouble to calculate it, that it is if any thing greater than what is stated.

To those with whom appearance is the main point in railway works, the design will probably afford some amusement; but every one will I think perceive that elegance of effect is not attempted, an economical and durable structure being the only object in view.

HERBERT SPENCER.

Derby, May 11, 1841.

ce to Drawings.

Fig. 1, Plate VII. is a side view of the bridge, part of the span is omitted in order that the remainder might be kept to as large a scale as the size of the Journal would admit. Fig. 2, is a transverse section of one of the suspensions or the cross trusses; and fig. 3, a transverse section of the centre suspension or cross truss. Fig. 4. enlarged view of the clutch box D, secured to the piers. Fig. 5. end view of the clutch box C; and fig. 6, a section of the same. The three last figures are drawn to a scale of ¾ of an inch to a foot.

CONDUCT OF THE GOVERNMENT TOWARDS THE ENGINEERING INTERESTS.

We have, on more than one occasion, thought it our duty to call the attention of our readers to the conduct which has long been pursued by the government and the legislature, as to all measures bearing upon the interests of the engineering profession. We are well aware that many of these measures, although weighing most strongly upon the engineers were directed against other interests, and cannot therefore be considered as purposely levelled against the profession; but, nevertheless, when we observe the tendency of measures more direct, and the uniform tenor of these proceedings, we are obliged to admit that either the policy or the inclination of the governing body is constantly directed to our injury. In whatever way we examine the measures affecting us we are impressed with this feeling, and now that we are enabled to look back and class together isolated events, we find an accumulation of evil in the highest degree threatening the profession. On the one hand our employment is proposed to be taken from us, and on the other we are to be placed under the government direction and control; so that both our moral and physical interests are equally concerned. It is perhaps fortunate that circumstances have intervened to prevent every attempt from being effective, but still a sufficient amount of mischief has been perpetrated to call for the serious attention of every one to the position in which he is placed. It might have been well at a former period for the civil engineer to say, that affects the marine engineer or the capitalist and not me, or for the practical engineer to say that has nothing to do with me, but now when we come to review the whole of these proceedings we find something which affects each individual branch, while there no longer remains a doubt that the whole body is in danger. What engineer when he considers the several government measures of the last four years can now flatter himself that he is safe, and that the attack on his neighbour is imminent of no danger to himself? Let him look at the Ten Per Cent. Deposit Clause, the Irish Railway Scheme, the Steam Navigation Bill and the Railways Bill; let him read the speeches of ministers, the reports of committees and commissioners, and the suggestions of commissioners, let him reflect on what has been attempted and then say if he dare to assign any limit to their future aggressions. We feel that the period has now arisen when it becomes the profession in a collective capacity to do in all its power for resisting present attempts, preventing future invasions, and remedying past evils, and unless these things be done and be done quickly too, we very much fear that an amount of distress and inconvenience will be inflicted on every individual, such as to make him bitterly regret his inactivity.

The Standing Order of the House of Commons requiring the payment of a deposit into the Bank of England of ten per cent. on the proposed capital of all public works, is a regulation the evils of which we have long deprecated. Many have shut their eyes under the delusion that either the order would be repealed from a conviction of its inefficiency, or such a change would take place in the money market as would enable it to be complied with. We were never so insane, for we considered that the same ignorance, which could lead to such an enactment in the teeth of reason and experience, would blind its partisans to any defect in its operations, and that whether the money market were either in a sound or unsound state, the impediment would be equally serious. The evils which have arisen to the profession from the stagnation of affairs have been quite enough without any aggravation, but now whatever may be the means or disposition of the monied interest, three years have passed over without a single act having passed for any public work of importance. After the present year we really cannot see where employment for a large part of the profession is to be obtained, for there will be neither railways, canals, docks, harbours, bridges, gas nor water works to be constructed, and no prospect, with means however abundant, of obtaining acts of parliament, except after the long period required by the standing orders. We foresaw what the result would be, and we gave warning of it, if therefore every one has remained lukewarm it has been from no default or neglect on our part, and those who will suffer will have themselves to blame for the event. The engineers must petition and obtain petitions from other parties for the redress of the grievances caused by the Ten Per Cent. Clause, for they may readily see that unless they put their shoulders to the wheel and sturdily too, no relief will they obtain. When an honourable member rose the last session to move for a reduction in the amount of the deposit, how was he supported, and what was the language of the President of the Board of Trade, the mouthpiece of that department in which all our evils have originated? He actually declared that no diminution in the number of acts had taken place, that no mischief was caused by the Standing Order, and finished by referring triumphantly to the number of notices then before the House of application for acts. Had he but enquired how many of these applications were rejected for non-compliance with this very regulation, and if he had enquired at the end of the session how many acts had passed, he would find that the account was merely a blank.

The Irish Railway Report, and the new Irish Railway scheme, are further developments of the same system; the progress of railways in Ireland has been checked, and the management of such as may be made is proposed to be entrusted to the government, the most inefficient body for the purpose which could possibly be selected, and which has already filled Ireland with monuments of jobbery and mismanagement. This new scheme must also be opposed as an emanation from the same stock, and as calculated by acting as a precedent to be productive of more immediate evil. The Steam Navigation bill exhibited, in all its deformity, the grasping ambition of the Board of Trade; the genius of our engineers was to be controlled, their plans revised, and their workshops taken from under their own management, and placed under the inquisitorial power of the government. The marine engineers were aroused, and the evil was warded off, but it must not be thought that an end is put to the existence of this monster, 'the snake is not killed but scotched,' and the spirit which animates it is too visible in the Railways Bill to allow us to doubt of its revival. These Railways Bills are too serious warnings of the danger of allowing the least tampering with our interests, to let us pass them by without calling the attention of our readers to the evils which are threatened by them. Discretionary powers are asked for, the future operation of which we are too well able to trace in those "shadows of coming events," the "Reports and Papers relating to Railways," presented to Parliament. Here we see military ignoramuses interfering with every part of the construction of railways and locomotives, putting the designs of the engineers under supervision, and suggesting that the workshop of the manufacturer of locomotives should be subjected to an inquisition. In fact, if our space permitted us, we might, on this subject alone, draw a fearful picture of the mischief which is threatened to every branch of the profession. Enough has now been said to call for an interference, and we have only to say further, that experience has shown that even the slightest opposition has been sufficient to check the Board of Trade in its mid-career, and if a sturdy opposition be organized, we are not without hopes of having all the grievances redressed. We again recommend the engineers to lose no time, or the profession will be stripped of its independence, and their offices of all appearance of business.

Neither are the evils confined to the engineers, but equally threaten other and more numerous classes. It is acknowledged that it is to the railways and other public works that we, in a great degree, owe the employment of the working classes, and diminution of the poor rates, and any sudden cessation of employment must be productive of the most disastrous consequences. The contractors, also, and subcontractors employed, and the several classes of tradesmen and labourers connected with them, are exposed to consequences equally ruinous; not only will they be put out of work, but their plant, tools and materiel becoming useless, must be sold at ruinous prices. A large amount of capital, also, which was directly employed in promoting the progress of the nation, has been, during the suspension, diverted, being either hoarded or rendered comparatively idle. Considered, indeed, in every possible way, whether on the broadest grounds or the narrowest, the measures of the government equally refuse the test, the interests of the nation being sacrificed through narrow-mindedness, or a love of jobbery.

PLAN FOR A NEW ASSOCIATION OF ARCHITECTURAL AND ENGINEERING DRAUGHTSMEN.

Among the various means which may be adopted in order to attain any desirable object, the association of numerous individuals who have a common interest in it, is one which has often proved successful in cases where isolated energy would have been unavailing. This may be observed in various instances, whether in pursuits of public utility, of pleasure, of charity, or of a private advantage.

It is now intended to suggest to the consideration of those concerned, whether this principle of association, so largely applied at the present day to objects of great public concern, might not be made useful to those engaged in one department of the arts of design with which it has hitherto had perhaps but little connection.

That class of artists is here alluded to, who are employed in a subordinate capacity in preparing the necessary drawings required previously to the execution of any great work either of architecture or engineering, to furnish the necessary illustration for the artificers who are to carry it into practice, and for the proprietor who is to possess it when completed.

It may be true that the different societies already formed both of architects and engineers, may have the effect of adding to the general stock of information, of increasing the means of knowledge, and maintaining the character of each profession with the public; but the union now advocated, is intended to be of a more humble kind of utility, less exalted in its objects, less interesting to the imagination, but it is conceived, not less adapted to meet the wishes and supply the wants of a considerable number of individuals.

However it may be that the young student of architecture (by which perhaps he merely means the drawing of architectural decoration), flatters himself that he is pursuing a "fine art," including all the grand and elevating, and beautiful attributes that may be connected with the term, he will probably find sooner or later, (circumstanced as the art is in these utilitarian days), that he cannot pursue it professionally without making it a different sort of business; a pursuit in which the physical qualities of objects shall be more considered than the æsthetical, in which the combination of the various talents of others shall be preferred to the concentration of a single isolated mind upon a single visionary object, in which the useful shall triumph over the beautiful, and the matter of fact over the imaginative.

These observations are put forward as prefatory to the main object of this paper, which is to suggest the formation of an Association of Architectural and Engineering Draughtsmen, for the purpose of enabling them more readily to communicate with each other, and with those at whose hands they expect employment; and of affording to the latter class, the means of readily obtaining that assistance of which they may stand in need, on terms the most equitable to both parties.

To obtain these ends, the means now proposed are, the collecting together at a given place for public exhibition, a number of specimens of the abilities of members of the associated body, whether applied in the different ways which are found practically useful in business, or exerted to produce results more attractive to the eye at first sight. For there should not merely be a display of the heaven-ward aspirations of unfettered fancy, exerted upon castles in the air, bridges over chaos, temples for which even if already erected it would be difficult to contrive any useful destination, and palaces adapted to pursuits of pleasure, unsuitable to our tastes, our habits, and to the climate of the country we inhabit; but places should also be assigned to those working drawings of common houses, and modern economical churches, those practical details of machinery, and surveys of parishes, and plans of estates, which would perhaps attract still more scrutiny from some of the frequenters of the proposed exhibition.

In reducing this plan to practice, several reasons might be alleged why the draughtsmen themselves ought to be the managers. They might make it one of their rules to be allowed respectively space for their drawings proportionable to the sums they subscribe to defray the necessary expenses. On the other hand contributions might also be levied from those whose curiosity led them to visit the collection, by the sale of catalogues, the possession of which might give a right of admission for a certain period.

The writer of these observations would be glad if they should have any effect in inducing others of the parties interested to join and carry his proposal into effect. Of course he would not be backward in lending his share of assistance so far as was within his limited means, and he should expect to be joined in doing so by some other of the younger members of the profession, who have expressed their concurrence in the views here expressed.

G. M.

ENGINEERING WORKS OF THE ANCIENTS, No. 6.

In our last we gave an account from Xenophon of the Athenian silver mines, which, by some inadvertence, was detached from this series of papers, and now we proceed to give what Diodorus Siculus says as to the gold mines of Ethiopia (Book 3.)

EGYPTIAN OR ETHIOPIAN GOLD MINES.

In the confines of Egypt and the neighbouring countries of Arabia and Ethiopia there is a place full of rich gold mines, out of which with much cost and pains of many labourers, gold is dug. The soil here naturally is black, but in the body of the earth, run many white veins, shining with white marble, (query quartz), and glistering with all sorts of other bright metals; out of which, laborious miners, those appointed overseers, cause the gold to be dug up by the labour of a vast multitude of people. For the kings of Egypt condemn to these mines notorious criminals, captives taken in war, persons sometimes falsely accused, or such against whom the king is incensed; and that not only they themselves, but sometimes all their kindred, and relations with them, are sent to work here, both to punish them, and by their labour to advance the profit and gain of the king. There are infinite numbers upon these accounts thrust down into these mines, all bound in fetters, where they work continually, without being permitted any rest day or night, and so strictly guarded, that there is no possibility or way left to make an escape. For they set over them barbarians, soldiers of various and strange languages, so that it is not possible to corrupt any of the guard, by discoursing one with another, or by gaining opportunities of familiar converse.

The earth which is hardest and full of gold, they soften by putting fire under it, and then work it out with their hands; the rocks thus softened, and made more pliant and yielding, several thousands of profligate wretches break it in pieces with hammers and pickaxes. There is one workman who is the overseer of the whole work, who marks out the stone, and shows the labourers the way and manner how he would have it done. Those that are the strongest amongst them, that are appointed to this slavery, provided with sharp iron pickaxes, cleave the marble shining rock by mere force and strength, and not by art of sleight of hand. They undermine not the rock in a direct line, but follow the bright shining vein of the mine. They carry lamps fastened to their foreheads to give them light, being otherwise in perfect darkness in the various windings and turnings wrought in the mine; and having their bodies appearing sometimes of one colour and sometimes of another (according to the nature of the mine where they work). They throw the lumps and pieces of the stone cut out of the rock upon the floor. And thus they are employed continually without intermission, at the very nod of the overseer or taskmaster, who lashes them severely besides. And there are little boys that attend upon the labourers in the mines, and with great labour and toil gather up the lumps and pieces hewn out of the rock as they are cast upon the ground, and carry them forth and lay them upon the bank. Those that are about thirty years of age take a piece of the rock of such a certain quantity, and pound it in a stone mortar with iron pestles till it be as small as a pea, then these little stones so pounded are taken from them by the women and older men who cast them into mills that stand together near at hand there in a long row, and two or three of them being employed at one mill, they grind it so long till it be as small as fine meal, according to the pattern given them. No care at all is taken of the bodies of these poor creatures, so that they have not a rag so much as to cover their nakedness, and no man that sees them can choose but must commiserate their sad and deplorable condition. For though they are sick, maimed or lamed, no rest nor intermission in the least is allowed them, neither the weakness of old age nor the infirmities of women are any plea to excuse them; but all are driven to their work with blows and cudgelling, till at length overborne with the intolerable weight of their misery, they drop down dead in the midst of their insufferable labours; so that these miserable creatures always expect worse to come than that which they at present endure, and therefore long for death as far more desirable than life.

At length the masters of the work take stone thus ground to powder, and carry it away in order to the perfecting of it. They spread the mineral so ground upon a broad board somewhat hollow and lying shelving, and pouring water upon it, rub it and cleanse it, and so all the earthy and drossy parts being separated from the rest by the water, it runs off the board, and the gold by reason of its weight remains behind. Then washing it several times again, they first rub it lightly with their hands, afterwards they draw up the earthy and drossy matter with slender sponges gently applied to the powdered dust, till it be clean pure gold. At last other workmen take it away by weight and measure, and they put it into earthen urns, and according to the quantity of the gold in every urn, they mix it with some lead, grains of salt, a little tin, and barley bran; then covering the pot close, and carefully daubing them with clay, they put them in a furnace where they abide five days and nights together; then after a convenient time that they have stood to cool, nothing of the other matter is to be found in the pots, but only pure refined gold, some little diminished in the weight.

And thus is gold prepared in the borders of Egypt, and perfected and completed with so many and so great toils and vexations. And therefore I cannot but conclude that nature itself teaches us, that as gold is got with labour and toil, so it is kept with difficulty, creates everywhere the greatest cares, and the use of it is mixed both with pleasure and sorrow. Yet the invention of those metals is very ancient, being found out, and made use of by the ancient kings.

ASSYRIAN ENGINEERING.

Keeping Diodorus Siculus as our guide, we now come to such notes as he has left of Assyrian engineering. (Book Second.)

WALLS OF NINEVEH.

Ninus (1950 B. C.) is styled the builder of Nineveh, having provided money and treasure and other things necessary for the purpose, he built a city near the river Euphrates, very famous for its walls and fortifications, of a long form; for on both sides it ran out in length above a hundred and fifty furlongs; but the two lesser angles were only ninety furlongs a piece; so that the circumference of the whole was four hundred and fourscore furlongs. And the founder was not herein deceived, for none ever built the like, either as to the largeness of its circumference, or the stateliness of its walls; for the wall was a hundred feet in height, and so broad that three chariots might be driven together upon it abreast. There were fifteen hundred turrets upon the walls each of them two hundred feet high.

BABYLON.

Semiramis, the wife of Ninus, was the founder of Babylon. To this end having provided architects, artists, and all other necessaries for the work, she got together two millions of men out of all parts of the empire to be employed in the building of the city. It was so built that the river Euphrates ran through the middle of it, and she compassed it round with a wall of three hundred and sixty furlongs in circuit, and adorned with many stately turrets; and such was the state and grandeur of the work, that the walls were of that breadth that six chariots abreast might be driven together upon them. Their height was such as exceeded all men's belief that heard of it (as Ctesias Cnidius relates). But Clitarchus, and those who afterwards went over with Alexander into Asia, have written that the walls were in circuit three hundred and sixty-five furlongs; the queen making them of that compass, to the end that the furlongs should be as many in number as the days of the year. The walls were of brick cemented with asphalte; in height, as Ctesias says, fifty fathoms; but as some of the later writers report, but fifty cubits only, and that the breadth was but little more than what would allow two chariots to be driven afront. There were two hundred and fifty turrets in height and thickness proportionable to the largeness of the wall. It is not to be wondered at that there were so few towers upon a wall of so great circuit, seeing that in many places round the city, there were deep morasses; so that it was judged to no purpose to raise turrets in places so naturally fortified. Between the wall and the houses there was a space left round the city of two hundred feet. That the work might be the more speedily dispatched, to each of her friends was allotted a furlong, with an allowance of all expenses necessary for their several parts, and commanded all should be finished in a year's time; which being diligently perfected to the queen's approbation, she then made a bridge over the narrowest part of the river five furlongs in length, laying the supports and pillars of the arches with great art and skill in the bottom of the water twelve feet distance from each other. That the stones might be the more firmly joined, they were bound together with hooks of iron, and the joints filled up with molten lead. And before the pillars she made defences (sterlings) with sharp pointed angles, to receive the water before it beat upon the flat sides of the pillars, which caused the course of the water to run round by degrees gently and moderately as far as to the broad sides of the pillars, so that the sharp points of the angles cut the stream, and gave a check to its violence, and the roundness of them by little and little giving way, abated the force of the current. This bridge was floored with great joists and planks of cedar, cypress and palm trees, and was thirty feet in breadth, and for art and curiosity yielded to none of the works of Semiramis. On either side of the river she raised a bank, as broad as the wall, and with great cost drew it out in length a hundred furlongs. Semiramis built likewise two palaces at each end of the bridge, upon the bank of the river, whence she might have a prospect over the whole city, and make her passage as by keys to the most convenient places in it as she had occasion. And whereas Euphrates runs through the middle of Babylon, making its course to the south, the palaces lie the one on the east, and the other on the west side of the river, both built at exceeding cost and expense. For that on the west had a high and stately wall, made of burnt brick, sixty furlongs in compass; within this was drawn another of a round form, upon which were pourtrayed in the bricks, before they were burned, all sorts of living creatures, as if it were to the life, laid with great art in curious colours. Our author goes on further to describe the ornaments of the palaces, which as less connected with our object we omit. He also describes the formation of a vaulted passage between the two palaces under the Euphrates, made by diverting the river. He says that the walls of this vault were twenty bricks in thickness, and twelve feet high, beside and above the arches; and the breadth was fifteen feet. The arches were of firm and strong brick, and plastered all over on both sides with bitumen four cubits thick. This piece of work being finished in two hundred and sixty days, the river was turned into its ancient channel again.

SEMIRAMIS'S WAY.

In a march towards Ecbatana, Semiramis arrived at the mountain Larcheum, which being many furlongs in extent, and full of steep precipices and craggy rocks, there was no passing but by long and tedious windings and turnings. To leave therefore behind her an eternal monument of her name, and to make a short cut for her passage, she caused the rocks to be hewn down, and the valleys to be filled up with earth, and so in a short time at a vast expense laid the way open and plain, which to this day is called Semiramis's way.

AQUEDUCT AT ECBATANA.

Besides this road, when she came to Ecbatana, which is situated in a low and even plain, she built there a stately palace, and bestowed more of her care and pains than she had done at any other place. For the city wanting water, (there being no spring near) she plentifully supplied it with good and wholesome water, brought thither with a great deal of toil and expense after this manner. There is a mountain called Orontes, twelve furlongs distant from the city, exceedingly high and steep for the space of five and twenty furlongs (query) up to the top; on the other side of this mountain there is a great lake which empties itself into the river. At the foot of this mountain she dug a canal fifteen feet in breadth and forty in depth, through which she conveyed water in great abundance into the city.

BRIDGE OF BOATS.

In her expedition into India, Diodorus relates that to cross the river, she carried with her boats, and made a bridge of boats by which she crossed.

SEMIRAMIS DEIFIED.

After her death or disappearance, Semiramis was adored by the Assyrians in the form of a dove, it being believed that she was enthroned among the gods.

Of this work Diodorus gives the following account. Memnon, the son of Tithon, governor of Persia, was in the flower of his age, strong and courageous, and had built a palace in the citadel of Susa, which retained the name of Memnonia to the time of the Persian empire. He paved also there a common highway, which is called Memnon's way to this day; but the Ethiopians of Egypt question this, and say that Memnon was their countryman, and show several ancient palaces, which (they say) retain his name to this day, being called Memnon's palaces.

We shall now cull from the Fifth Book of Diodorus a number of desultory notes on different subjects, and first as to the

IRON MINES OF ETHALIA.

This island (Elba) abounds with iron stone, which they dig and cut out of the ground to melt, in order for the making of iron; much of which metal is in this sort of stone. The workmen employed first, cut the stones in pieces, and then melt them in furnaces, built and prepared for the purpose. In these furnaces, the stones by the violent heat of the fire, are melted into several pieces, in form like to great sponges, which the merchants buy by truck and exchange of other wares, and transport them to Dicearchia, and other mart towns.

TIN MINES OF BRITAIN.

Now we shall speak something of the tin which is dug and gotten here. They who inhabit the British promontory of Bolerium, by reason of their converse with merchants, are more civilized and courteous to strangers than the rest are. These are the people that make the tin, which with a great deal of care and labour they dig out of the ground; and that being rocky, the metal is mixed with some veins of earth, out of which they melt the metal, and then refine it. Then they beat it into four square pieces like to a die, and carry it to a British Isle near at hand, called Ictis (Wight).*

GOLD MINES OF GAUL—ARMS.

In Gaul there are no silver mines, but much gold, with which the nature of the place supplies the inhabitants, without the labour or toil of digging in the mines. For the winding course of the river washing with its streams the foot of the mountain, carries away great pieces of golden earth; and when it is so done, they cleanse them from the gross earthy part, by washing them in water, and then melt them in a furnace; and thus get together a vast heap of gold, with which not only the women, but the men deck and adorn themselves.

As the arms used by the Gauls are calculated to show the progress made by them in the working of other metals, we copy the following descriptions. Some carry on their shields the shapes of beasts in brass, artificially wrought, as well for defence as ornament. Upon their heads they wear helmets of brass, with large pieces of work raised upon them for ostentation sake, to be admired by the beholders; for they have either horns of the same metal joined to them, or the shape of birds and beasts carved upon them. Some of them wear iron breastplates, and hooked; but others, content with what arms nature affords them, fight naked. For swords they use a long and broad weapon called *spatha*, which they hang across their right thigh by iron or brazen chains. Some gird themselves over their coats, with belts, ornamented with gold or silver. For darts they cast those they call lances, the iron shafts of which are a cubit or more in length, and almost two hands in breadth.

CELTIBERIAN MODE OF PREPARING IRON.

They carry two edged swords exactly tempered with steel, and have daggers beside of a span long, which they make use of in close fights. They make weapons and darts in an admirable manner, for they bury plates of iron so long under ground, till the rust hath consumed the greater part, and so the rest becomes more strong and firm: of this they make their swords and other warlike weapons, and with these arms thus tempered, they so cut through every thing in their way, that neither shield, helmet, nor bone can withstand them.

SILVER MINES OF SPAIN.

Having related what concerns the Iberians, we conceive it not impertinent to say something of their silver mines; for almost all this country is full of such mines, whence is dug very good and pure silver; from which those who deal in that metal gain exceeding great profit. The Pyrenean mountains are the highest and greatest of all others, and being full of woods, and thick of trees, it is reported that in ancient time this mountainous tract was set on fire by some shepherds, and continuing burning for many days together, (whence the mountains were called Pyrenean or fiery), the parched superficies of the earth sweated abundance of silver, and the ore being melted, the metal flowed down in streams of pure silver, like a river; the use whereof

* Valso.

being unknown to the inhabitants, the Phenician merchants bought it for trifles given for it in exchange, and by transporting it into Greece, Asia and all other countries, greatly enriched themselves; and such was their covetousness, that when they had fully laden their ships, and had much more silver to bring aboard, they cut off the lead from their anchors, and made use of silver instead of the other. The Phenicians for a long time using this trade, and so growing more and more wealthy, sent many colonies into Sicily and the neighbouring islands, and at length into Africa and Sardinia; but a long time after the Iberians coming to understand the nature of the metal, sank many large mines, whence they dug an infinite quantity of pure silver, (as never was the like almost in any other place of the world), whereby they gained exceeding great wealth and revenues. The manner of working in these mines, and ordering the metal among the Iberians is thus; there being extraordinary rich mines in this country of gold, as well as of silver and brass, the labourers in the brass take a fourth part of the pure brass dug up, to their own use, and the common labourers in silver have a Euboick talent for their labour in three days time; for the whole soil is full of solid and shining ore, so that both the nature of the ground, and the industry of the workmen is admirable. At the first every common person might dig for this metal, and in regard that the silver ore was easily got, ordinary men grew very rich; but after Iberia came into the hands of the Romans, the mines were managed by a throng of Italians, whose covetousness loaded them with abundance of riches, for they bought a great number of slaves, and delivered them to the task masters and overseers of the mines. These slaves open the mouths of the mine in many places, where digging deep into the ground, are found massy clods of earth, full of gold and silver; and in sinking both in length and depth, they carry on their works in undermining the earth many furlongs distance, the workmen every way here and there making galleries under ground, and bringing up all the massy pieces of ore, (whence the profit and gain is to be had), even out of the lowest bowels of the earth. There is a great difference between these mines and those in Attica; for besides the labour, they that search there are at great cost and charge; and besides are often frustrated of their hopes, and sometimes lose what they had found, so that they seem to be unfortunate to a proverb. But those in Iberia who deal in mines, according to their expectations, are greatly enriched by their labours; for they succeed at the very first sinking, and afterwards by reason of the extraordinary richness of he soil, they find more and more resplendent veins of ore, full of gold and silver; for the whole soil round about is interlaced on every hand with these metals. Sometimes at a great depth they meet with rivers under ground, but by art give a check to the violence of their current; for by cutting of trenches under ground, they divert the stream; and being sure to gain what they aim at, when they have begun, they never leave till they have finished it; and to admiration they pump out those floods of water with those instruments called Egyptian pumps, invented by Archimedes the Syracusan, when he was in Egypt. By these with constant pumping by turns they throw up the water to the mouth of the pit, and by this means drain the mine dry, and make the place fit for their work. For this engine is so ingeniously contrived, that a vast quantity of water is strangely with little labour cast out, and the whole flux is thrown up from the very bottom to the surface of the earth. The ingenuity of the artist is justly to be admired, not only in these pumps, but in many other far greater things, for which he is famous all the world over, of which we shall distinctly give an exact enumeration, when we come to the time wherein he lived. Now though these slaves that continue as so many prisoners in these mines, incredibly enrich their masters by their labour, yet toiling night and day in these golden prisons, many of them by being over wrought, die under ground; for they have no rest or intermission from their labours; but the taskmasters by stripes force them to intolerable hardships, so that at length they die most miserably. Some that through the strength of their bodies, and vigour of their spirits are able to endure it, continue a long time in those miseries, whose calamities are such, that death to them is far more eligible than life. Since these mines afforded such wonderful riches, it may be greatly admired that none appear to have been sunk of later times; but in answer thereunto the covetousness of the Carthaginians, when they were masters of Spain, opened all.

In many places of Spain there is also found tin; but not upon the surface of the ground as some historians report, but they dig it up, and melt it down as they do gold and silver. Above Lusitania there is much of this tin metal that is in the islands lying in the ocean over against Iberia, which are therefore called Cassiterides; and much of it is likewise tranported out of Britain into Gaul, the opposite continent.

(To be continued.)

HISTORICAL SKETCH ON THE USE OF BRONZE IN WORKS OF ART.

By Cesar Daly, Architect.

(Translated for the Civil Engineer and Architect's Journal from the Revue Generale de l'Architecture.)

Some years ago, many, otherwise remarkable for their learning, would ask in what degree modern civilization differed from that of ancient Greece or Rome; and even in the present day there are some who will ask the same question, even in England, in the heart of London, or of Manchester, or of Birmingham, with a thick cloud of coal smoke from a hundred factories rolling in volumes over their heads. To these a feature so extraordinary, unknown to the ancients, tells no tale, though it is one which marks most strongly the character of modern times, superior in its power over physical nature, and the great development it has given to the efforts of mechanical invention. So generally, indeed, is the industrial character of modern times unnoticed, that we have scarcely any accounts of the various branches of manufactures, or of the subject generally, although this practical history is one which has the greatest interest in relation to the human race. This history in all its ramifications, whether as to the tools employed or the materials upon which they are exercised, would open a wide field of research, capable of ample gratification, notwithstanding the manner in which the records are dispersed. Among the metals and their alloys known at an early period, none has been devoted to such important uses as bronze, to which we shall devote the present essay.

Had the art of metallurgy been better known in distant periods, and the use of iron and steel more prevalent at a former epoch, or even had copper been more extensively used, we should have remained ignorant of much of the material history of antiquity, for both of the former metals disappear under the influence of rust, and copper is also a sufferer from the action of damp. Thus, while in the Portici Museum the bronze articles are well preserved, those of copper have been more or less affected, and those of iron are scarcely recognizable.

Copper was known in the earliest times, and is mentioned by Moses; but the difficulty of working it with the hammer, and the high degree of heat requisite to melt it, greatly limited its use. It was fortunately not long before the properties of a mixture of copper and tin were discovered, a mixture with greater tenacity and resistance than copper alone, fusible at a lower temperature, and denser than the mean of its components. By this mixture was obtained a metal which readily flowed into every part of the mould, so as to take a correct impress of the pattern, while it was hard enough to wear well, was not brittle, and so far from being injured by oxidation, which only affected it slightly, it was preserved by it from the action of the atmosphere, taking the beautiful colour which is so much admired. The providential discovery of these properties doubtless gave a great impulse to the infant civilization of the early stages of society, affording at the same time a greater facility for manufacture united with greater durability. Thus it came to be employed for arms and edge tools by all the nations of antiquity, whether Indians, Chinese, Egyptians and Hebrews, Greeks, Etruscans, Romans or Celts. In connexion with them, indeed, it might be well said that for many long ages bronze was the iron of the ancients. The fine arts were not long in making use of it, and we find it ministering to the decoration of many of the most ancient monuments of Egypt. In Scripture we find that the Philistines, after the capture of Sampson, loaded him with chains of brass, and Josephus relates that Solomon employed Hiram of Tyre to make two columns of bronze richly decorated, eighteen cubits high, twelve cubits in circumference, and four inches in thickness, or four times as thick as that on the Column of July. The columns were placed at the entrance of the porch of the Temple at Jerusalem. From these works we may judge that working in copper and brass was already of old date at this distant period.

We are quite in the dark as to the processes of melting and forms of the furnaces used by the ancients; but we can readily judge, from the interest, in these days of the progress of science, still attached to the casting of bronze on a large scale, of the difficulties to which workmen must have been subjected in the rude state of chemistry and metallurgy. In Greece the use of bronze was very common; the Chalciæcos, at Lacedemon, was a temple of bronze, dedicated to Minerva, and executed about 750 years before the Christian era by the celebrated Gitiadas, poet, sculptor, and architect. Every part of this building, from the top to the bases of the columns, was entirely covered with plates of bronze decorated with mythological sculptures. Pausanias (B. 10, ch. 5,) relates that when the temple of Apollo at Delphi was rebuilt for the third time, it was constructed of copper, which is not surprising, adds he, as Acrisius had a bronze room made for his daughter, and as there is still to be seen at Sparta the temple of Minerva Chalciœcos. He goes on further to say, "at Rome, the place in which justice is administered excites surprise by its grandeur and magnificence; but what is most admired is a bronze ceiling, which extends from one side to the other. The same author, who attributes to Theodosius and Racos of Samos the discovery of founding statues in bronze,* informs us that it was about the year 600 before our era that this art was first practised. This, like all the other arts, made great progress in the time of Pericles, but did not reach its full height until the age of Alexander, when each of the principal cities of Greece possessed several thousand figures of bronze, among which were some enormous colossi. This is what Pliny says in his 24th book, sec. 18, "There are numberless instances of boldness in this art, for we see that enormous colossal masses have been executed as large as towers. Such is the Apollo of the Capitol, brought from Apollonia, a city of Pontus, by M. Lucullus; this is thirty cubits high, and cost fifty talents. Such is the Jupiter of the Campus Martius, consecrated by the Emperor Claudius, and called Pompeian, because it is near Pompey's Theatre; such is that of Tarentum, executed by Lysippus, and which is forty cubits in height. What is most remarkable as to this figure is, that it is so well balanced that it may be moved by the hand, although it could not be upset by a whirlwind. The most admired of these colossi was that of the Sun at Rhodes, made by Chares of Lindus, a pupil of Lysippus. This figure was seventy cubits high, was overturned 56 years after its completion by an earthquake; but cast down as it is, it still excites admiration. Very few men can put their arms round the thumb, the fingers are bigger than most statues, and the hollows in the broken limbs are like the yawning mouths of caves; inside are seen stones of large size, which were used to settle it on its base. It is said to have been finished in twelve years, and to have cost three hundred talents, a sum produced by the warlike engines of King Demetrius, when he raised the siege of Rhodes. In the city are a hundred other smaller colossi, each of which would be worthy of bestowing distinction on the town in which it might be placed; besides these are five colossi of gods by Bryaxis. Italy has also produced colossi, for we see in the library of the temple of Augustus, the Tuscan Apollo, which is fifty feet high from the toe, and in which it is difficult to tell which to admire most, the bronze or the beauty of the workmanship. Spurius Carvilius had a Jupiter made for the Capitol out of the helmets, cuirasses and greaves of the conquered Samnites. The size of this statue is such that it may be seen from the place in which is the Latial Jupiter. But in our times, Zenodorus has surpassed all the figures of this kind in height, in the Mercury which he made for a city of the Gauls in Auvergne. This was ten years in execution, and cost four hundred thousand sisterces."

It is probable that these colossi were formed of a number of pieces secured with nails, like so much brazier's work, for it is thus that the ancients made their metal statues before they had acquired the art of founding. At Lillebonne in Normandy, a few years ago, in the course of the excavations for uncovering the Roman theatre, a bronze Mercury was found made in this manner. In reading the travels of Pausanias in Greece, we cannot but feel surprised at the immense number of bronze works in sculpture which he meets with at every step, particularly when we recollect that this country has been in the possession of the Romans for three centuries, and that they had already, on several occasions, carried away thousands of bronze figures. Of 33 colossi described by the tourist, 30 were of bronze, the three others of wood; he also describes 32 equestrian statues of bronze and 24 chariots, at least of natural size, sometimes with two, and oftener with four horses, and holding one or two figures. Some were accompanied by runners or grouped with men on foot who led them; in fine, he mentions more than 40 animals of considerable size, also of bronze. And yet Pausanias only visited a part of Greece. It was of bronze that the Athenians, after the death of Pisistratus, formed the first quadriga, in memory of their fellow countrymen who died while fighting for their native land Of bronze also is constructed, in our days, the Monument of July. Bronze is, in truth, the symbol of strength, and it is interesting to observe how the same metal has been chosen, at two periods so remote, to consecrate the remembrance of facts having so much resemblance.

The Romans, as we have seen from extracts before given, made frequent use of bronze, and like the Greeks, employed it in the form of candelabræ, lamps, furniture, triclinia, altars, tripods, tools, fastenings, letters for monumental inscriptions, window fastenings, &c. The doors were sometimes plated with bronze, secured with nails of the same metal; such as those of the Pantheon. Pliny (B. 34, § 7,) says that the ancients were accustomed to make the threshold and gates of temples of bronze. Ancient gates entirely formed of bronze are still to be seen in the church of St. Cosmo and St. Damian in the Forum at Rome, formerly the temple of Romulus and Remus, and this luxury was not exclusively confined to temples, for, 380 years before our era, the ornaments were of bronze on the doors of the house of Camillus. By means of cramps large masses of bronze ornaments and carvings were fastened on monuments by way of decoration. On bronze tablets were engraved laws, treaties of peace, and public acts intended to be made known to posterity. Three thousand of these tablets were destroyed in the fire of the Capitol, in the time of Vespasian. Capitals were also made of bronze, which were secured on cores of stone. Pliny relates that "C. Octavius, who conquered Perseus in a naval action, erected, in honour of his triumph, a double portico, which was called Corinthian because the capitals of the columns were of bronze; this portico was near the Flaminian Circus; the capitals of the Pantheon, placed there by Agrippa, are of the same metal." The Romans further applied bronze in the execution of works on a large scale; the framing of the Pantheon was constructed of bronze, and, according to Serlio, who had examined it in its place, the different pieces were hollow; they were put together in the same way as woodwork. The caissons of the vault of this monument were also of bronze, and the circle which frames the opening by which the Rotunda is lighted still remains. In the baths of Caracalla the ceiling of the immense hall known as the Cella Solearis was formed of a net-work of bronze; a fact of which M. Blouet did not seem to be aware when he published his restoration of that monument. The ancients also constructed roofing of bronze, for at Rome, 212 years before the Christian era, the temple of Vesta, at Rome, was covered with tiles of bronze, and so, at a later period, was the Pantheon. As to bronze statues, there was at Rome a number truly prodigious, brought from all the great cities of Etruria, Greece, Sicily, and Asia Minor. Scaurus having erected a temporary theatre at Rome, towards the end of the republic, decorated it with three thousand of these statues.

The art of the founder naturally underwent all the vicissitudes of the other arts; in the time of Nero the decadence had already commenced, it not being possible to cast the colossal statue of that emperor, modelled by Zenodorus, and which was to have been 110 feet high,* although a century afterwards the beautiful equestrian statue of Marcus Aurelius was cast. Falconnet, in comparing these two facts, endeavours to make out a case for an attack on Pliny; but it seems to us that the circumstances may be reconciled by supposing that casting in bronze had been momentarily neglected before the time of Zenodorus, and that they had been more successfully cultivated in the time of Marcus Aurelius, for a similar circumstance happened in our own days. The brothers Keller, under Louis XIV., carried the art of casting in bronze to a high degree of perfection; but under Louis XV. the founders were not so good; and in the early part of the empire, great difficulties were met with in executing works of this kind, whilst now the art of casting in bronze has made greater progress than ever. Besides, it may be said that whenever a process is not carried on scientifically, while the reason of the different phenomena has not been discovered, and the artist consequently is reduced to take the bare results of experience for his guide, the neglect of the art for some time is enough to cause the facts to be forgotten, and the guides are consequently lost. This, however, cannot happen when the theory of an art is firmly based on scientific principles, and the reason of the phenomena is consequently understood; drawing our conclusions, from which we may say that the art of casting in bronze will henceforward never be lost, even should it be neglected for centuries; a few trials would be enough to bring it back to the point at which it had been left.

In the Middle Ages.

During the Lower Empire, nothing remarkable was executed except some bronze gates, and the process of casting seems to have been quite lost at Constantinople. The gates of the Basilica of St. Paul, at Rome, were cast in the 11th century by Staurachios Tychitos of the isle of Chios. In the 11th century were cast those of the basilica of St. Zeno, at Verona, on which are represented passages of the Old Testament and the miracles of the saint. The bronze gates of St. Mark, at Venice, were also brought from Constantinople in the 12th century.

Germany possesses some bronze gates of the 11th century, such as those of Mentz and Augsburg. In 1330, Andrea Ugolino executed two panels for gates in bronze, from the designs of Giotto, for the Baptistry of Florence. Ghiberti finished his chef d'œuvre in 1424. In the 15th and 16th centuries several gates of bronze were cast at Venice, Padua, Bologna, Florence, Pisa, Loretto, &c.; but these works were not sufficient to prevent the art of casting in bronze from falling

* Vide B. 6, ch. 14; B. 9; B. 10, also Pliny, B. 24, ch. 6.

* Pliny, B. 34, § 7. Suetonius says 120 feet.

into complete oblivion, and during almost the whole of the middle ages this art was wholly limited to casting bells.

Modern Times.

At the Revival appeared several bronze works of art, in which Italian artists, and particularly those of the famous school of Florence, in the beginning of the 16th century, distinguished themselves most, and contributed most efficaciously in diffusing a taste for it in different European countries. The sculptor Torrigiani passed several years in England, where Henry VIII. gave him several commissions for bronze works. Primaticcio also executed, at Fontainebleau, several bronze statues from antique models which he had brought from Rome. At this time there were several French artists who were employed in brass founding; but their modes of proceeding seem to have been very imperfect, for Benvenuto Cellino relates in his memoirs that during his stay in France, he wished to cast a bronze statue of Jupiter about six feet high, which had been ordered of him by Francis I.; "but never having been engaged in this kind of work," said he, "I consulted some of the old masters of Paris, and explained to them how we managed in Italy. They replied that their manner was different, and that if I would leave it to them, they were sure to make my model in bronze such as it was in clay. I made my bargain with them; I promised them the price they asked, and even something over. I put my hand to work, but I could see well enough that they were not trying the right way. I wanted also to try myself upon a head of Julius Cæsar, larger than life, made after the model of a small head designed from a beautiful antique which I had brought from Rome. I added to it a head of the same size which I modelled from that of a beautiful girl in my service, and whom I called Fontainebleau, from the name of His Majesty's favourite palace. When I saw my furnaces finished, and our models baked, I said to my master founders, I fear that the Jupiter will not come out well, because you have not left draught enough for the air; but they replied that, if they did not succeed, they would give me my money back again, and that I should find less chance of success in the Italian method. This took place before some gentlemen whom the king often sent to see how I was getting on. Before casting the melted metal for the Jupiter, the founders wanted also to place my two heads to cast them at the same time, feeling persuaded that their mode would not succeed, and that it would be a pity to lose such fine works; but the king, who learnt it, sent to them to tell them that they must think of learning from their master, and not of teaching him. Then, smiling, they put their Jupiter in the pit, and I also arranged my two heads at the sides, and when the metal was ready, we left a free passage for it. Our moulds were quite filled, and we were all happy, I, with having succeeded in my way, and they in theirs. They asked me for something to drink, and I gave them plenty of refreshments; they then asked me to pay the sum I had promised them. You smile, said I to them, then, but I very much fear that you will cry soon; for I saw that more metal ran into the Jupiter than was wanted, and that is the reason that I shall not pay you until it is all right. These poor men felt that I was in the right, and went away without saying anything. They returned the next day very quietly to empty their pit, and began with the two heads, which were perfect; they then came to the Jupiter, which caused them to cry out, as I thought, for joy, and which made me run, but I found their faces like those of the soldiers who watched the tomb of Christ. You see, said I, what has happened to you from not believing me; you would have reaped more profit and I more honour. Learn, then, to work, and not to laugh at what is said to you. They acknowledged their error, but they regretted their time and expenses, on account of their families, whom they had to keep, and for which y should be obliged to run into debt. Never mind that, said I, I pay you as soon as the treasurer pays me; for I pitied them, because they had worked with a good heart." Further on, telling the story about his statue of Perseus, which was also cast in bronze, he says, "The model of the Medusa, made of clay, and well-secured with iron, had already passed through the fire; I had already covered it with wax, and the bronze only was wanting. I had my furnace built directly; I took such good care, and the figure came out so clean, that my friends thought it was all done, like the French and German founders, who never finish their bronzes after they come out of the fire, being doubtless ignorant of the practice of the ancients, and many of the moderns, who finish off with a hammer and chisel." This remark o would lead us into the belief that the French and German contained a good deal of tin; for when the bronze contains a good deal of copper, its fusion requires a very high temperature, which vitrifies part of the sand of the mould, which, becoming attached to the figure in cooling, requires to be removed; on the other hand, a larger proportion of tin making the metal more fusible, the result was less to be feared. Benvenuto, not contented with having executed so many admirable works, left also a treatise on casting in bronze, which was long the best manual on the subject.

(To be continued.)

ON THE POWER OF THE SCREW.

Sir—There is an article by Mr. Cussen on the above subject in your number for May, on which allow me to make the following remarks.

His first objection to Mr. Bridge's formula seems to arise from a want of acquaintance with the style of mechanical language. Surely Mr. B. just meant by *d*, the pitch, or distance between the centres of the threads, or, in general, the distance between the threads, just as we talk of the length of an engine beam, when we mean its length between the end centres. Why did we not get an example from Bridges, to test his meaning of the ambiguous *d*?

As to his second objection, he denies that the diameter of the cylinder is of no importance. One of 12 inches diameter, he says, will sustain six times the weight with the same power that one of 2 inches will do. Now this is not the point at issue. We are not talking about mere pressure, but of moving power. Let him consider that when the machine is set in motion, the velocity of the weight up the inclined plane increases as the diameter of the cylinder. Thus his advantage is neutralized by necessitating a greater velocity. But again, it is evident that with the same power at the same leverage, whatever be the diameter of cylinder, the weight that can be raised through the *same height* in one revolution must be the same. It is an established law that the momenta of power and weight are equal; therefore the momentum of the power, (viz. the product of its intensity by its velocity) being constant, that of the weight must also be constant; *i. e.* since the velocity of the weight is constant, (as it is raised through the same height each revolution,) therefore the intensity of the weight also is constant, and this inference is quite independent of the size of cylinder.

His third objection demonstrates that he has not thought three times on what he says. He confounds the *moment* of power with its *momentum*; a vital error. The moment of power is its intensity into its leverage, but its momentum is its intensity into its velocity. Now the relative velocities of *the* power and weight are the spaces passed through by each in one revolution; therefore the velocity of the latter is the pitch of the screw, and that of the former just the circumference of the circle described by its leverage. Therefore this element is chosen correctly in Bridge's formula.

ON LONG AND SHORT CONNECTING RODS.

Observing that there exists a controversy respecting long and short connecting rods, allow me to present the following demonstration of

Fig. 1.

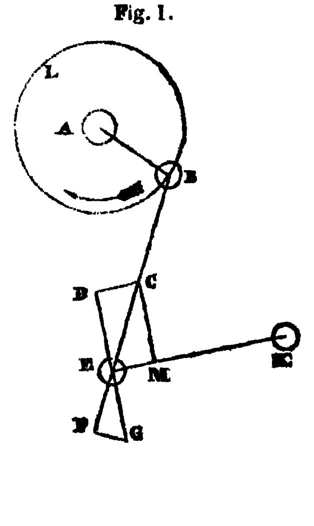


Fig. 2.

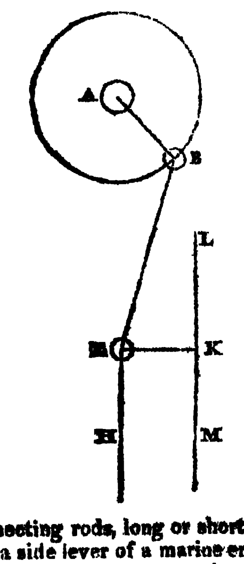

the justness of the action of all connecting rods, long or short.

Let $k\,e$ fig. 1, be the crank end of a side lever of a marine engine, $e\,b$ the connecting rod, and $a\,b$ the crank moving as per arrow in the circle $b\,l$. The resistance at b acts always in the line of the connecting rod; let $e\,c$ represent it in direction and intensity, just when the slightest overplus of power would set the engine in motion. The power acts always in the line $g\,e\,d$ perpendicular to $k\,e$; complete the parallel-

[illegible] are in equilibrium. Therefore, ec being the resistance, de is the power, and de or em, the pressure on the centre k, which, as it never has motion, is of no consequence. Taking any point f in be produced, draw fg perpendicular to it, meeting eg in g; ef and eg will express the relative virtual velocities of the resistance and power respectively, and fg, the passive *lateral* motion of the line of resistance,—passive, I say, for its direction is at right angles to this, and it is therefore of no consequence. But the triangles feg, dec, are similar, therefore $de : ec :: fe : eg$, and $de \cdot eg = fe \cdot ec$, that is, the momenta of the power and resistance are equal. The same conclusion is due at every other point in the circle bl. An addition to the power will set the engine in motion, which would be uniformly accelerated were it not that the resistance increases with the velocity. However great, then, the power may be, there will ultimately obtain a uniform motion, when the power and resistance will be in equilibrium, their momenta being equal, as before. Therefore in connecting rod motion, force for force is given and received, and there is no loss essential to that motion.

The point e of ke moves alternately in a circle. The greater limit of this angular vibration is a semicircle, in which case $ke = ab$. The smaller limit is a straight line: an indefinitely small portion of a circle, its radius ke, being indefinitely long. This limit is practically exemplified in engines in which the piston rod is at once jointed to the connecting rod, as in the annexed sketch, fig. 2, of this motion, in which ab, and bc are the same as in last figure; ek the cross head, bearing perpendicularly on the slide surface lm, parallel to the piston rod ke, evidently in the same way as if bearing round a centre k, infinitely distant.

Upon the whole, then, short and long connecting rods on the same length of crank must be equally effective, whatever peculiarities there be.

I am, Sir, your obedient servant,

DANIEL CLARK.

Phœnix Iron Works, Glasgow,

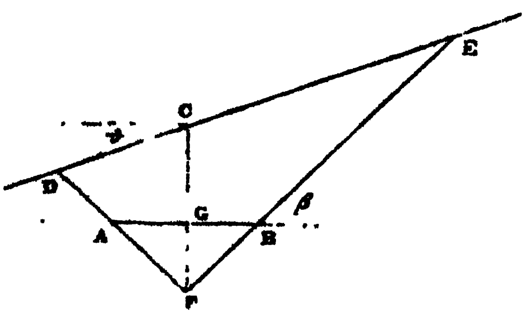
SLOPES IN SIDELONG GROUND.

SIR—The following formula for "setting out slopes in sidelong ground," requiring the distances to be measured along the ground, and not horizontally, has, for that reason (particularly where the ground is very steep), an advantage over the formula in your last number; should you agree with me in this opinion, you will perhaps find a place for it in your next Journal.



Let $2w$ = width of the railway = AB.
$\beta = \angle$ of the slopes.
$\theta = \angle$ of the natural ground.
h = depth of cutting = CG.
Then $(w \tan\beta + F\angle) = CF$.

$$CD = (w \tan\beta + h) \frac{\sin CFD}{\sin CEF} = (w \tan\beta + h) \frac{\cos\beta}{\sin(\beta + \theta)}$$

$$CE = (w \tan\beta + h) \frac{\sin CFD}{\sin CDF} = (w \tan\beta + h) \frac{\cos\beta}{\sin(\beta - \theta)}$$

The slopes remaining constant then $w \tan\beta$ will be constant, and therefore the angle CDF will also be constant.

I am, Sir, your's most obediently,

W. R.

Manchester, June 8, 1841.

THE NELSON COLUMN.

SIR—As the Nelson column rises to view, we become sensible of what appears to be a great mistake in the *position* of it, and which ought to have been in a line drawn from the centre of the portico of the National Gallery through the Statue of Charles I., which appears as it ought to do in the centre of Whitehall; whereas the column seen from the same spot, will appear considerably to the right of the statue, and will be engaged with Drummond's Bank, the Admiralty, &c., instead of appearing to rise in the centre of the street, and thus producing a most awkward effect, whether as seen from the centre of the portico, or in approaching it as you come from Whitehall. This might easily have been avoided by placing the column in a line with the statue, which line, though not *quite* perpendicular to the plane of the portico, would have deviated from it in so very slight a degree as not to be perceptible to the eye, while the present position will produce an effect so glaringly awkward as at once to strike every beholder.—The mistake of the architect consists in having thought it necessary to place the column in a line perpendicular to the plane of the portico, whereas his object should have been to make the column appear to rise in the centre of the street, as seen from the portico which could have been done by the very slight and imperceptible deviation from the perpendicular above mentioned.

I am, Sir, your's,

ÆSTHETICUS.

ON THE THEORY OF BARS.

"Lorsque l'homme s'ecarte de la vraie cause d'un objet quelconque, il doit se considerer dans les tenebres, et il est forcé de chercher des arguments absurdes, dans lesquels il se perd, ce qui fait que les sciences deviennent ridicules dans l'opinion du vulgaire."—*Cuvier on marine deposits.*

SIR—Pursuant to the notice I gave in the last number of your valuable Journal, I take leave to send you for insertion the following observations on a "New Theory of Bars, &c., by Mr. Brooks."

The importance of the subject to this great naval and nautical nation, and to the maritime commerce of the world, should admonish us to pursue the investigation of this matter with the most cautious and serious consideration, for as it is well observed in the quotation at the head of Mr. Brooks' treatise, "our errors in this matter are of more importance than in mere objects of taste, luxury, or pleasure, because they will ever result in injury, or in the loss of some previous advantage." Let us also bear in mind Cuvier's reproof quoted above.

It does not appear requisite that I should refer to the many theories quoted by Mr. B., the controversy so prevalent at present, and in past times, in the scientific world on the subject of bars, demonstrates that it has not received that attention and examination which can lead to a right conclusion as to their cause, and what are the most eligible means to obviate the many evils incident to their existence; but I do presume that my subsequent remarks, based on facts and practical observations, will prove, that if the desideratum has not previously been developed, Mr B. has not reflected any new light on a subject hitherto by many supposed to be enveloped in darkness.

It appears apposite to notice that Major Rennel, quoted by Mr. B., p. 1 and 2, states, "that mud and sand suspended in the waters," (*i. e.* the egress waters) "during their motion are deposited when that motion ceases, or rather they are gradually deposited as the current slackens, according to the gravity of the substance suspended;" and the late Mr. Telford gave a similar exposition. I did not expect in this age of the world, any one would reject such an evident and irrefutable fact, a principle ever in operation during the discharge of the egress tides, or currents; but Mr. B. p. 4, says, "I venture to submit, that it is insufficient," (*i. e.* the Major's thesis) "to account for the formation of bars, because the operation described (the deposit), as producing the latter (the bar), takes place in all rivers, in a greater or lesser degree, and in those which although their waters are abundantly loaded with sand or mud, are nevertheless free from bar." Mr. B. therefore disputes the accuracy of the Major's deduction, because it is the result of a partial, and not of a general law; why, Mr. B. has endeavoured to rest his entire case on local and partial data, and neglected to observe general principles.

That all rivers, harbours, bays, estuaries, &c., where the waters pass with a velocity sufficient to hold matter in suspension, have *beds* of sand, &c., is quite correct; but where the receding waters do not return or run out into the ocean with a force adequate to disturb the deposit that occurred during the quiescent state of the waters, as described by Major Rennel, there are truly no bar or [illegible] *tion* can take place; for matter does not move without an impetus. Mr. B. then *de facto*, leaves the Major's thesis (with which I agree), where he found it, based on the solid and immoveable foundation of truth.

It is quite obvious that the Major has adopted the thesis that I have, viz.

1st. That wherever rivers, sluicing, or backwaters disembogue into the ocean, either under a natural or artificial impetus, and run with sufficient velocity to hold matter in suspension, and cause a conflicting action with the waters into which they pass, there a bar is formed.

2nd. That wherever there is an absence of egress waters, currents, tides or sluicing power, and where no conflicting action ensues, there no bar exists.

3rd. That to these rules there are no exceptions throughout the world, for wherever nature is placed under similar circumstances, she is immutable in her results.

> "Here then we fix the universal cause,
> God acts by general, not by partial laws."

These primordial, universal, and indisputable facts are deduced from an extensive field of observation of many years, and on various harbours, rivers, &c., during which time I have visited the Baltic, Gulf of Finland and Bothnia, Russia, Prussia, Denmark, Sweden, Norway, Jutland, Friesland, Holland, Belgium, France, Spain, Portugal, the Mediterranean, Africa's shores, and many harbours of the united kingdom,—but all this devotion has been dealt with by Mr. Brooks in a most summary way, and to refute my theory he has used the following words, page 5, chap. 6, viz.:—"That the casual direction of the lower reach, or the position of the mouth of the river cannot truly be assigned as the cause of the existence of a bar, is easily proved by observation on rivers subject to great variations at the entrance, the bar being always found to exist independent of the direction of the discharge into the sea, this fact at once refutes the third and fourth theories."—In this extract there seems to be two distinct facts, *i. e.* the casual direction of the lower reach, and the independence of a bar, in the direction of the discharged waters, that is, he means that the deposit or bar, does not occur in the direction or course of the egress waters. With respect to Mr. B.'s assertion of the independence of the bar, of the egress waters, I have much to say, if he be correct, he has indeed "at once refuted my theory," and would prove it to be a mere visionary and hypothetical deduction; but I will proceed to show the converse, and that he has committed, as in other parts of his book, an egregious error. If the reader will turn to the author's theory, subsequently here inserted, where he uses the *wedge* to aid his illustration, and where the battle with the elements occurs at the first quarter flood, he will find it stated, "that in the conflict the sand, or other materials, which it was (*i. e.* the effluent waters), capable of holding in suspension previously to its encountering the conflicting action of the flood tide, yields it to the latter, and when this takes place the *bar is formed;*" now observe, Mr. B. tells us that the material which drops and forms the bar, is brought down into the ocean by the egress or effluent waters, that as it advances onwards, (in its own direction of course), it encounters the flood tide, and where it meets that tide there the bar is formed; so that Mr. B. himself destroys the premises which he had the boldness to adopt for the annihilation of my thesis. The positive and irresistable fact is, that all bars are formed in the direction of the effluent waters, the latter are the impetus to the matter held in suspension, and that matter must fall in the direction of the impelling power, as a shot from a gun, the ball from the foot, or the deposit from the stream of the milldam.

Passing on towards Mr. B.'s theory, I notice in chap. 2, page 19, "pier harbours which though free from bar in their natural state, are well known to become encumbered by them, on the introduction of the scouring power," here I suspect he cast his eye southward on Lowestoft Piers. Scouring power no doubt (this is my principle), causes a bar, no matter whatever way or manner it is conducted to the sea, naturally or artificially, whether there be piers or no piers.

The commencement of chapter 11 is a mere repetition of my second proposition, "That whenever a river or harbour approximates to the condition of a simple inlet for the reception of the tide it would have no bar." I endeavoured some time ago, in a conversation with Mr. B., to illustrate this truism by a reference to various harbours where the water did not pass into the sea, with a sufficient velocity to disturb the bed, there no exterior deposit could take place; no matter whether such a harbour be naturally or artificially constructed. Norway, Scotland, Ireland, Scilly Islands, Minorca, and Malta harbours, are of the first kind; Ramsgate, Margate, Scarboro', Cronstadt, Elsinore, &c., the latter.

In page 18, Mr. B. in noticing the geological features of the Yorkshire coast, says, "That a residence of some years on its shores, and a close observation enables him to state, that those seas that break on the outward platform, (the outer flat) are much heavier than those which break nearer the shore." I bear testimony to the accuracy of this fact, taught me in my boyish days by the boatmen, sailors and fishermen, that on all flat shores, or in different elevated platforms (if they must be so designated), the sea loses its force, where it is first intercepted by the shore, and as it advances and rolls up the inclined plane, so the concave dimension diminishes, till at last it finishes in a mere ripple, or tiny billow.

I have now arrived at our author's theory, and it is *multum in parvo.* "During the period of the first quarter flood, the current, in lieu of being able to take its natural upward course, as in rivers where *no bar exists*, is opposed, or effectually checked, by the effluent backwaters; the declination of the stream in the lowest division of the river presenting a head which ensures a strong downward current, long after the tide would have been able to maintain an upward course, provided the backwater had a free discharge; at this period the flood tide, by reason of its greater specific gravity, occupies the lower stratum of the tide-way, and like a wedge endeavours to force its course up the channel, which it is unable to effect, but merely elevates the lighter effluent water, the lower strata of which, being checked by the opposition of the tidal waters, yields to the latter the sand or other materials which it was capable of holding in suspension, previously to its encountering the conflicting action of the flood tide; where this takes place the bar is formed."

Having shown that Mr. B. has attempted to refute my thesis by the aid of a fallacious assertion, I now proceed to prove that he has based his own on a sandy foundation. He commences this part of his work by stating that the current, in the first quarter flood, is not able to take its natural course upwards, as in rivers where no bar exists—that is, where a bar does exist it is not able—and that this inability is occasioned by the conflicting action of the waters (and which conflicting action only exists where a bar is already formed,) and where this takes place (the conflicting action), there the bar is formed. So that, in order to sustain his "novel theory" on the cause of bars, he first must have a bar to produce the cause of a bar, and thus the effect produces the cause, and with this mode of reasoning, illogical as it is, he has attempted "at once," and with one fell swoop, *nolens volens*, to throw me overboard, and include in his general sweep, all who have attempted by principle or practice, ancient and modern, a development of the cause of bars. Mr. Brooks requires a backwater falling out of a sloping river, and that water to be opposed by a first quarter flood, and a bar itself to produce a bar; he appears not to be aware that in various parts of the world bars have accumulated where there is an entire absence of his causes, and not only at places "which approximate to the condition of a simple inlet," but where the only existing cause, amongst those which he assigns for a bar, is the egress or scouring waters; examples of which we have in the Baltic, the Black, and other seas.

In my examination before a Committee of the House of Commons in 1826-1827, on the proposed Lowestoft Harbour, I then stated "that so soon as the scouring water should be applied as then proposed, a bar would accumulate where no deposit or bar previously existed, and if the sluicing were continued the harbour would be so blocked up that small vessels only could enter at high tide." He need only refer, to prove the accuracy of his prescience, to the present state of the bar at that harbour, and the fact that about £150,000 have been expended thereon, the entire of which has been recently offered for sale by the Loan Commissioners for £17,000, it being completely lost as a harbour of refuge for which it was intended."

It is an incontrovertible fact, that the greater the quantity of egress, or sluicing waters, and the more rapid their course, the greater is the exterior deposit. The Mississippi and other large rivers demonstrate this fact—the entrance to that queen of rivers is most difficult in the spring of the year, when the melting of the snow on the mountains increases the quantity and rapidity of the egress waters, so as to carry with them trees, earth, and other matter, all of which are deposited on the extensive bar, at its outlet, and it does not again decrease until after a long continuous dry season, when the quantity of egress water is reduced.

Mr. B. follows his "new theory" by stating, "that he might easily extend his illustrations," and adds that the "direct tendency of the whole period of the ebb, when unobstructed by the tidal currents, must be to reduce the bar." This is really hypothetical. That the ebb or outgoing waters have a direct tendency, and are the real cause of all exterior deposits or bars, &c., I have asserted for the last 20 years, the accuracy of which I will now attempt to prove. At the Neva, Gulf of Finland, the Narva, Dantzic, the Danube, the Nile, and many other places, the current, without intermission (there being no *flood tide*), is perpetually running out at the rate of six, seven, or eight knots per hour, and yet the old entrances to those rivers have been blocked up by impassable bars, and either new passages have been cut into the ocean, or the egress waters have forced a passage out in a new direction; here we have an absence of quarter flood, sloping, and of the difference in the gravity of the two waters, no salt water being in the vicinity of the disemboguing site of the above rivers.

I must now take leave to make an observation on Mr. B.'s proposition to take away the shoals or deposits in the Thames, at Woolwich by scouring, and not by dredging, the result of such an operation (if it were accomplished) would be, that the matter moved could only be impelled onward while the impetus was retained, but so soon as that ceased, a re-deposit would occur which would occupy the same extent of the bed of the river, which it had previously done—he seems not to be informed of the effect produced on Barking Shelf, removed by dredging although an immense accumulation of sand and shingle, the base of which appeared at low water—but I will not further interfere with the interior part of his subject, that is all plain sailing, no insurmountable difficulty occurs in attempts to improve inland navigation, there we have no impinging billow, or any material effect produced by the winds or tides.

Before I conclude, allow me to give some farther proofs of the accuracy of my two first propositions—New Zealand, "The entrance to the bay at Wangarver is 11 miles broad, perfectly safe, and without a bar; the bay is studded with rocks, (so are the harbours I have previously referred to as being free from bar). The water is deep close to the shore. The bays of Plenby and Port Nicholson are similarly formed and are free of bar, although no back waters. The harbour of Hokianga with an extensive interior river, where the waters run out at every ebb tide, there a bar exists. In the West Indies, at St. Lucia and the Havannah, both splendid harbours, but have neither rivers, back waters, nor bars.

I remain, Sir, your obedient servant,

HENRY BARRETT.

CANDIDUS'S NOTE-BOOK.

FASCICULUS XXVIII.

"I must have liberty
Withal, as large a charter as the winds,
To blow on whom I please."

I. THE absurd trifling, the stupid pedantry, the puerile discussions that at one time engaged the attention of architects, almost surpass belief, and are to be paralleled only by the quibblings of the schoolmen and divines of the dark ages, when theology was reduced to idle disputation, and religion to the practice of the grossest superstition. Were it not so authentically recorded, that it is impossible to doubt the fact, hardly would it be now believed that the problem proposed by Sansovino as to the mode of obtaining the *exact half* of a metope at the angle of a Doric entablature—the *semimetopia* of Vitruvius—made a noise throughout Italy, and excited the attention of all the architectural geniusses of the time! Had Sansovino and his contemporaries been equally scrupulous and precise in all other matters, we might excuse their overniceness in regard to such *difficiles nugæ;* instead of which they were most latitudinarian, even shamefully so in many respects. Like those people who make no difficulty of jumping over mountains, yet break their shins against straws, who can swallow millstones whole, yet are choked by a pound of butter, they were not at all shocked at some of the grossest violations of architectural propriety. In some of Sanmicheli's plans, for instance, the rooms are so frightfully out of square, that no two sides are parallel to each other. Symmetry, too, in respect to the position of doors and windows within buildings, is totally disregarded, as if it were perfectly indifferent whether it were attended to or not. The designs of Il Divino Palladio, as he has sometimes been called, abound with scandalous defects of this kind. I suspect that his "*divinity*" must have been somewhat of a piece with that of Il Divino Aretino, a monster who ought to have been hanged, drawn, and quartered. Such "divinities" as the last must be inquired for in the infernal regions.

II. Nothing can be more opposed to every legitimate principle of art and æsthetics, than the attempt to reduce the different orders to so many express and immutably fixed types. The consistency so aimed at is attended with almost the worst species of inconsistency, because it totally excludes such modification as may be most suitable for the particular case. It is time for us to get rid of all the mechanical quackery to which we have so long submitted, and which has reduced architecture, as generally practised, to little better than a mere handicraft trade—to copying certain individual parts met with in former styles of the art, without any regard either to the genius of the styles themselves, or to the circumstances of the building required. What puerile trifling it is to affect scrupulous nicety as to the express shape and proportion of every little detail belonging to columns which are to be stuck up by way of portico before a dowdy house or other building, which is thereby only rendered a grotesque absurdity! In most other matters people think of attending a little to consistency and common sense; or should they fail to do so, they must submit to the derision of their neighbours. But in architecture, the most ridiculous incongruities and *disparates* are tolerated—tolerated! they are even applauded; and *bêtises* that would hardly be endured in the preparations for a temporary fête, may be perpetrated with impunity in buildings intended to be permanent.

III. "Geniality" is not an English word,—hardly can it be said to be as yet adopted by us; and what is more to be regretted, there is, I apprehend, very little of the thing itself among the artists of this country. At all events very little evidence of it is to be discerned in our architecture. Looking at the majority of the buildings which have been erected of late years—and they certainly have not been few in number, they must be allowed to confirm such opinion, disagreeable and unflattering as it is in itself. If we find the styles respectively aimed at, copied with passable fidelity, without any particularly gross violation of their principles, it is nearly the utmost that can be said in their favour; and as matters stand, such poor negative merit must be received as a positive one. How very far, however, it stops short of geniality, hardly needs to be said, it being sufficient to remark that the latter draws out, concentrates, and heightens all the good qualities of a style, and at the same time imparts to them some fresh charm, some additional unborrowed value; and that, even though the subject should be an unpromising or inconsiderable one in itself. If he cannot always create favourable opportunities, a man of real talent will, at least, do the very utmost that circumstances will permit—will convince us that he has not satisfied himself with merely turning out a decent, workman-like job, but has applied himself to his task as to a labour of love, with the feeling of an artist, not of a builder—not of a tradesman. Were we to believe some of those who, albeit without aught of the artist in their constitution, style themselves architects, their genius would blaze forth upon the world, were but sufficient opportunities afforded them. The man who cannot put together two ideas—except detestable ones—for a moderate-sized house, or church, would be able, nevertheless—if we choose to believe him—to erect the most splendid palatial and ecclesiastical edifices. John Nash was an architect of this stamp, and as it most unfortunately happened, opportunities, both many and of no ordinary kind, were thrown in his way. How he acquitted himself of them is but too well known. It is to no purpose that Theodore Hook affects to consider him the victim of harsh and illiberal criticism; or that *Professor* Brown, as he facetiously designates himself, tells us, *ex cathedrâ*, I suppose, that John was "a man possessing great taste for the grand and the picturesque." For the GRAND! Surely the learned Professor must be speaking sneeringly and ironically, for never did Nash, on any one occasion, even approximate to the grand or the dignified in architecture. Never did he get nearer to it than 170 degrees E. or W. longitude of it. Still, incredible as it may appear, the enlightened Professor is not joking, but intends it to be taken as his serious opinion; for he elsewhere speaks of "the magnificent houses along the Strand, King William Street, and the splendid houses in the Bayswater Road!!" adding, "but when we behold the more magnificent columnar edifices on the east side of the Regent's Park, and the crescent on the west, where the houses are crowned with octagonal domes, we stand astonished with admiration!!" Most undoubtedly we do so, Mr. Professor Brown, for we stand absolutely "putrified" with astonishment that such masses of ugliness and vulgarity should ever have been erected. However, perhaps the Professor judges of Nash by his own quantum and calibre of talent and taste, in which case he has undoubtedly sufficient cause to look upon Nash as a very great man, he himself being but a mere dwarf and pigmy by the side of him, as his own designs abundantly testify. When we look upon those architectural abominations and atrocities, we do indeed stand astonished, but it is with the astonishment of unmitigated horror and disgust. Oh, Professor Brown, Professor Brown, unlucky was the day and hour when you dubbed yourself with that ambitious title. Could you get rid of it again—but no, that is impossible; it will stick to you for ever; it will render you the laughing-stock and the byword of the profession. You cannot *un-Professor* yourself now, or divorce yourself from the ill-sorted companion to which you have married your name. Doctors' Commons won't help you, Dr. Lardner will not run away with that "better-half" of you. Professor Brown you have made yourself, and Professor Brown you must now continue to be in spite of yourself. You cannot metamorphose back again into plain Dick Brown. I pity you, I compassionate you, I condole with you—yet infinitely more do I pity and compassionate those unfortunate devils who shall imbibe their architectural taste from the designs of Professor Brown!

ARCHITECTURAL ROOM, ROYAL ACADEMY.

(Concluded from page 181.)

Having made a month's pause, we will avail ourselves of it, before we resume our own comments, to express our astonishment at an opinion we have in the interval met with, in regard to the architectural portion of the Exhibition. Either we, or the writer in the Mirror, is egregiously mistaken, for he tells his readers that the designs for new churches and other public buildings are "very numerous and in good taste;" whereas we think that there are rather fewer of the kind than usual, and those for the most part of very mediocre quality. In fact, it is only by referring to the catalogue and our own notes, that we can recollect above one or two, so little is there at all striking in them—except, indeed, it be by making an unfavourable impression. Such, certainly, is the case with respect to one, which is singled out by the writer in the Mirror, viz. 1059, "The Estate building at Hackney for J. B. Nichols, Esq." by J. A. Taylor, which consists only of a crowd of ugly houses detached from each other, but all *dittos*, instead of being varied as to design,—no doubt a laudable idea enough, because it saves the architect a great deal of *trouble*, without, perhaps, at all diminishing his per centage. Such architecture may do very well for the latitude of Hackney, but it is not fit to be paraded upon the walls of a Royal Academy. Or if such things must be exhibited, they must also take their chance of being somewhat cavalierly treated, since it is not every one who is so complaisant as the critic in the Mirror—a mirror, by the bye, which flatters most confoundedly.

Some may think that the Mirror's opinions are scarcely worth noticing at all, since, instead of being put into positive and tangible shape, its criticism amounts to little more than quoting from the catalogue the titles of such designs as it would recommend, and have us understand to be meritorious, without our being so unreasonable as to ask for reasons. The Art-Union—from which something better might be expected—deals in nearly the same sort of criticism, being exceedingly laconic and oracular, or, we might say, that one had need consult an oracle in order to understand upon what grounds it mentions for approbation some of the things it does—for instance, "No. 1053, Design for an Opera House, by J. C. Tinckler." We confess that that subject struck ourselves, but certainly not with admiration, the taste displayed in it, seeming to us in some respects absolutely barbarous, and what was not positively barbarous, to be no more than barely endurable. Far more readily do we agree with the Art-Union when it says, "the churches now being erected through the country, such as that at Nuneaton by Mr. T. L. Walker, seem, thanks to the Church Commissioners, to be designed by the dozen, with no better recommendation than cheapness, and no other better point about them than the certainty that they cannot last many years." As to the quality of the design thus referred to, we ourselves cannot pretend to offer an opinion, because that and about half a dozen others of the earlier numbers in the architectural section of the catalogue, are put out of sight, perhaps very deservedly so, for there certainly is nothing at all prepossessing in what can now be distinguished of them—nothing to make us particularly anxious to become more intimately acquainted with them. That a Royal Academy, not bearing the title of an Hibernian one, should persist, year after year, and in spite of repeated remonstrances, in adhering to the blundering practice of *exhibiting* drawings by hanging them where so many frames and blank paper would cover the walls—if covered they must be—quite as well, is nothing short of marvellous. If no remedy can be devised, it would at all events be but becoming and proper that the highest and tip top places should be assigned to the works of the Professor and other Academician architects; let them be exalted, and there is no doubt that they would instantly perceive and correct what they now cannot discern, viz. the gross absurdity of admitting more drawings than can be properly seen when hung up. We certainly meet with a good many whose absence would have been no loss to the exhibition; and the very first upon the list, viz. No. 956, "View of Hyde Park Gardens, Paddington," is among them, it being a subject we are sorry to see either in reality or representation—a heavy mass of bloated insignificance. No. 980, "Lonsdale Square, Islington," R. C. Carpenter, is another "flare-up" concern of the same kind. The houses that are shown may be passable enough as dwelling-houses, but as architecture they have no pretensions, nor has a drawing of this class much claim to be admitted into an academical exhibition. There are one or two designs for the Taylor and Randolph Buildings at Oxford, and we may mention that by Messrs. Mair and Browne (No. 965), as being entitled to considerable praise—as much better, in fact, than any of those for the same edifice which were exhibited last year; and it is stated to have been one of the five selected in the first instance by the committee. We should have examined it more attentively than we did at the time, had we then known as much as we now do of the design which has been adopted. We need not inform our readers that this last is by Mr. Cockerell, the Professor of architecture; but we may assure them it is by several degrees more fantastical and outré than his design for the Royal Exchange, and in some respects perfectly nondescript as to style. How the Professor—who seems ambitious of obtaining for himself the title of the English Borromini—can reconcile the *extravaganzas* he has there shown, with the precepts he delivers *ex cathedrâ*, cautioning the students against aiming at mere showy effects, rather than architectural propriety, it puzzles us to guess;—and it would, no doubt, puzzle him still more to explain.

Messrs. Gough and Roumieu's design for "St. Pancras' National Schools," (No. 976) is a small but pleasing composition, in the Tudor style, with a rather unusual degree of decoration, therefore should the building itself turn out to be as satisfactory as the drawing represents it,—which, however, is not invariably the case, it will be nearly the best thing of its kind in the metropolis. No. 1096, "Interior of the new Library at Roehampton Priory," by the same architects, is also sufficiently creditable to them; but they must excuse us for not admiring that for "St. James' Dormitory Chambers, as proposed to be erected" (No. 1080)—yet, we hope, as never will be erected. Were it not too late, we should enter a similar protest against No. 977, "An Elizabethan Villa, now building at Hammersmith, from the designs of Mr. S. Gomme," for it is a most Gommy or '*gummy*' affair, as a friend of ours would call it,—a specimen of all that is most hideous and barbarous in that style, without any of its redeeming qualities; and it would seem that the architect's aim had been rather to exaggerate than to mitigate any of its deformities. It may be excusable enough in the possessor of a genuine relique of Elizabethan architecture to be somewhat jealously proud of it—for its antiquity if for nothing else; but that at the present day any one should think of building for his own habitation a 'bran new' absurdity of the kind we here behold, is to us most marvellous.

No. 982, "New Park near Devizes, showing the principal front, with alterations and new carriage entrance," does not impress us with any very high idea of the taste or ability of Messrs. Finden and Green. How far they have doctored up the house, we know not: for aught we can tell they may have improved it, but if they have it must have been deplorably bad indeed before, since it is bad enough—we should say, intolerably bad even now.

Though we wish there were a far greater proportion of interior views than we ever meet with among the architectural drawings, we could very well have spared one of those which Mr. T. L. Walker has sent, of the "Governor's Dining Room at the new Hospital, Bedworth, Warwickshire," viz. Nos. 1014 and 1088, they being nearly duplicates, showing opposite ends of the same apartments, which although very fair as to design, is not so remarkable as to call for such an unusual degree of illustration; and we almost wonder that two drawings of the same subject should have been admitted, when others were turned away for want of room; or that, as both were received, they were not hung up together as companions. It appears, moreover, to us that either the perspective is very faulty, or else the windows themselves poor in character, owing to the excessive breadth between the mullions, according to the drawing.

No. 1027, "View of the London and Brighton Railway Terminus, now erecting at Brighton, from the designs of" D. Mocatta, is exceedingly poor both as a drawing and a design; and we are afraid he cannot shelter himself under the excuse that the subject was an unfavourable one in itself, or that he was cramped in his resources; because there is certainly enough of it as to extent, and the same degree of decoration might have been far more effectively applied. The extended colonnade below is in itself appropriate and convenient enough, but as it is made to project from the loftier mass behind it, it seems rather to encumber than to ornament it; neither is it by any means unexceptionable in regard to design. We are very far from objecting 'upon principle,' to arches being turned upon columns: on the contrary, we consider some of the instances of such combination to be among the happiest effects of Italian architecture. What we complain of is, not that such mode is here adopted, but that it is treated most insipidly, and that want of artistical feeling pervades the whole design.

At first sight we mistook No. 1056, for a view of the Parthenon or some other Grecian Doric temple, but on referring to the catalogue "A project of a Curesal or Pump-room to be erected on St. Ann's Cliff, Buxton, with plans, elevations, and sections," by W. L. Granville; and there certainly are some miniature drawings on the margin, which may be the plans, &c., but which it is utterly impossible to make out at such a height above the eye; consequently all we can say is that, however ingeniously Mr. G. may have contrived the interior of his building he has not shown much invention, or particular propriety of character in the exterior of it.—We begin to get altogether sick of Grecian temples.

The "Façade of the Wesleyan Centenary Hall," No. 1058, is now exhibited as executed, the Lysicrates Monument, stuck upon it last year, being lopped off from it; which being the case we think that the frame might have been reduced also, for at present the drawing occupies twice the space the subject itself requires, and every square inch is or ought to be of value in this room.

No. 1065, "The Library, Northwood House," G. Mair, is a small interior subject that appears to deserve a more favourable situation than it has obtained. No. 1071, "Entrance Lodge to be built at Deane Park, the seat of the Earl of Cardigan," J. Crake—a name new to us—is also a clever design, in the Gothic style. We cannot say quite so much for No. 1110, "Design for a Gothic Roof in Guildhall, London," E. Woodthorpe, for though the drawing itself is a showy and elaborate interior, the new timber roof here proposed, is a poor and meagre affair. If, too, it is intended to make any alterations at all in that edifice, we think that the one most required, is to give it an entirely new exterior, the present one being so atrociously ugly that we wonder how even the corporation of London can stomach it. Taste they have,—at least have the reputation of possessing it, but it does not lie in architecture.—No. 1108, "Entrance front of a design for a Mansion to be erected at South Elkington, Lincolnshire," E. B. Lamb, is a good composition in what may be called the irregular or picturesque Italian villa style,—with a carriage porch and tower over it. While the offices are kept subordinate to the house itself, they are made to aid the general character very much, being treated consistently with it, and so as to give importance to the principal mass, and at the same time be of sufficient architectural importance in themselves. Both picturesque expression and propriety have been consulted, by introducing only a single ground floor window on this side of the body of the house: not only is great privacy thus secured, and the noise and bustle of horses and carriages shut out from the sitting rooms, but a degree of piquancy is imparted to the whole; the internal arrangement cannot be understood until we actually enter the house, which is not the case where there is a range of windows on each side of the entrance. And here we will bring our strictures to a conclusion, lest by continuing them we should be compelled to change our tone again, and have to speak not quite so favourably. Towards some our silence may be unbecoming, but there are a great many who have reason to congratulate themselves that we lay down our pen before we give them a touch of it. Very possibly we have passed over several drawings that we should have been able to notice with approbation, had they been hung where they could be seen; so long as the present system is persisted in, such is likely enough to be the case. That it is persisted in is no fault of ours: on the contrary, did it depend upon ourselves, we would correct it instanter,—if no other way, by cutting the formidable Gordian knot, and reducing the Five tiers of frames containing architectural drawings, now hung up, to Two. Three of them might very well be spared, for the quality of the Exhibition would be rather improved than not by their absence.

ON THE INJURIES TO HEALTH OCCASIONED BY BREATHING IMPURE AIR IN CLOSE APARTMENTS.

the various inventions and improvements which distinguish the age we live in, it is lamentable to observe what little attention has been paid to the ventilation of apartments in which we are destined to pass the greater portion of our lives, and in which a constant and well-regulated supply of the element we breathe, is so essential to bodily health and mental enjoyment.

This inattention can only be accounted for either by the want of education in the major part of that class of persons who call themselves builders, or an apprehension on the part of those who aspire to the more elevated designation of architects, that the introduction of any thing new would expose them to the charge of a want of taste, or of that acquaintance with the style of the ancients to which it is the fashion so strictly to adhere (imitation being, in their opinions, more deserving of commendation than originality of design, or a desire to meet the improvements of the age, and fashion of than health). If they construct our doors and windows in so a manner as to exclude every possible particle of air, they flatter themselves with having attained an advantage to which the inhabitants of ancient Greece and Rome did not aspire. They should, however recollect, in their apparent anxiety for imitation, that the ancient architects of warmer climates did not overlook the necessity of a free admission of air, and also that a constant supply and free circulation of this element, is as necessary for sustaining life as a given quantity for the combustion of the fuel we require to warm our apartments; our builders, nevertheless, only provide for the latter, as if the former, although the more important, was of minor consideration, or that they conceived the chimney draft sufficient for both purposes, when, in reality, it does not answer that for which it is principally intended—as by far the greater portion of the heat generated in our open fireplaces is carried up the chimney, by sharp currents of air from occasional openings of doors, or such crevices as it may force its way through, being moreover, frequently productive of serious bodily injuries, particularly to those of delicate frames, while it cannot be sufficient for the purposes of wholesome ventilation; this air being colder than that already in the room, is consequently of greater specific gravity, and must form a lower stratum, not unfrequently felt by those placed round the fire, suffering from an undue proportion of heat at one side and of cold at the other.

It should also be borne in mind, that the openings of our fire-places being seldom more than three or four feet from the floor, the upper stratum of air is neither removed or purified by this under current, and must, from being breathed over and over again, be productive of most prejudicial effects, and that the contamination of this atmosphere is considerably augmented at night by the combustion of lights, the quantity of air breathed by an ordinary sized person being calculated to be about 2000 cubic feet per hour, and that two mould candles consume as much of the oxygen of this air as a human being, and that the nitrogen and carbonic acid gas which remain are peculiarly inimical to animal life, and that when carried up by the currents occasioned by combustion and respiration they form an upper stratum, where they remain, and must be repeatedly inspired before they make their escape into the chimney—the only ventilating flue with which our houses are provided.

It should also be observed, that the heat thus generated is in proportion to the quantity of oxygen abstracted from the atmosphere, which enters into combination with the carburetted hydrogen of the flame of candles, coal gas, oil or other inflammable matter, from which light is produced, that every cubic foot of carburetted hydrogen consumed unites on an average with two cubic feet of oxygen, that portion of the atmosphere required to support animal life, and that the product of this combustion is about 2½ inches of water, and one of carbonic acid gas, which, when inhaled in its pure state, proves instantly fatal, and the greater the proportion we inhale in addition to the animal vapours evolved from the lungs and skin, the more pernicious the effect.

Supposing for example that the perfect lighting of an ordinary sized apartment requires 15 cubic feet of carburetted hydrogen per hour, this would form about a pint and a half of water and 15 cubic feet of carbonic acid gas, for whenever carburetted hydrogen gas is burned with oxygen, or atmospheric air, these are the products of the combustion, whether the carburetted hydrogen is obtained from wax, tallow, oil, or coal. If, therefore, this lighting continue in an unventilated apartment for seven hours, one gallon of water is produced, the greater part of which must be deposited on the walls, windows, furniture, polished metal, or other cold surfaces with which it comes in contact, and to some articles of this nature it is known to prove highly prejudicial, in addition to the injury to health occasioned by an increased quantity of moisture mixed with the air we breathe—as one of the principal functions performed by this air for the preservation of health, is to carry off with it a considerable quantity of vapour in order to prevent its undue accumulation on the lungs; it is therefore evident, that after it has been already so loaded, it cannot properly perform these functions, and that consumption and other complaints are thus frequently induced.

The prejudicial effects of carbonic acid gas (which is the same as the choke damp of mines) as well as of the nitrogen of the air, which is set free by the abstraction of the oxygen, (and amounts in quantity to four times that of the oxygen,) are well known, and ought by all possible means to be provided against. This has been attended to within the last few years in our public hospitals, and the mortality, in consequence, considerably decreased, and likewise in several of our manufactories and public establishments, where the diseases generated, by the numbers of persons congregated in such establishments, have proportionably diminished. In the House of Commons, where hundreds of members with hundreds of candles burning at night tended so much to vitiate the atmosphere, important improvements in lighting as well as ventilation have been recently made, but in our domestic establishments little or no attention has been paid to this important subject, and the foundation of a variety of diseases must be the result, particularly from the foul air breathed at balls or other crowded assemblies.

The confinement of air in our churches and places of public worship, must also be highly prejudicial, as we are frequently exposed on entering one of these edifices in the summer months to an atmosphere 10° or 15° below that of the external air, independent of the stagnant state in which it has been allowed to remain during a whole week—often vitiated in a greater degree by the gaseous matter evolved from human remains, and even in private houses much inconvenience is experienced from the stagnant state of the atmosphere in close and gloomy weather, an evil which has been considerably augmented by close stoves, when made of iron and heated to a certain temperature.

But if stoves were constructed of masonry throughout, as in many other countries, or of fire tiles, or porcelain plates, embedded in mortar with well-regulated flues, they would be far preferable to open fire places, this substitution of imperfect conductors of heat being not only consistent with the soundest principles of economy in the preservation of heat, and its more uniform distribution through apartments, but more salubrious than the methods usually resorted to in this country of warming air by contact with iron stoves or pipes.

The healthy appearance of those who pass the greater part of their time in the open air sufficiently indicates its advantages; armies are also well known to have far greater numbers on the sick list when well housed, than when exposed in a campaign to the vicissitudes of the season, for weeks and months without any other covering than the canopy of heaven, or occasionally of a tent or hut, or the shade of a tree. These facts ought to satisfy us that we should admit the air as freely as possible into our apartments at all seasons of the year, as the temporary and often imaginary inconvenience of a little cold, when compared with the decided disadvantages of breathing impure air, is by far the lesser evil.

When ventilation in large establishments or public buildings can only be obtained by artificial means, it is produced by pumping air in, or drawing it out by a fan worked by steam or other adequate power, and affording it the means of free circulation either cooled, heated, or in its natural state, through well-regulated apertures in the floors, walls, or ceilings, and in coal mines by flues or shafts in which constant currents of air are maintained by the combustion of fuel or coal gas; this system might also be easily introduced into houses already built, by means of the existing chimneys; but with still greater facility if our architects and builders were to direct their attention to those points when erecting new ones.

The importance of this subject has been frequently pointed out by scientific men of considerable eminence, without attracting that attention which would have been the means of rescuing many persons from being imperceptibly hurried to an untimely end. It is, therefore, to be hoped that the powerful engine of the press will continue to lend its aid in exposing these evils, until it impresses upon the public mind, and more particularly upon our architects and builders, the urgent necessity of providing against them. Is it not possible, by some simple contrivance, to make the heat produced in the lighting of apartments available for their perfect ventilation? if any of these gentlemen succeed in so doing, they will be entitled to greater gratitude for this achievement in the purification of an element so essential to the preservation of our lives, than any claimed by those heroes whose victories have contributed so much to the miseries of the human race, and the destruction of the human species.

But we ought not, perhaps, to be so much surprised at the slow march of intellect in this respect, when we find so many centuries to have elapsed before it was so generally admitted, as at present, that pure water, another element bountifully supplied by nature, is preferable to any other beverage for insuring the health and happiness of mankind, and when we have so many temperance societies and other advocates for impressing upon the minds of our fellow subjects the necessity of becoming converts to the imbibing of this element in its pure state, ought we not, with still greater reason, to endeavour to make a similar impression as to the advantages of inhaling, with equal purity, the lighter fluid, of which we stand so much more in need, and which we so much more frequently require?

A gasometer of sheet iron formed of 269 pieces, and of an immense capacity, arrived at Antwerp on the 8th instant, by the *Soho* steamer from England, intended for the gas works in that town.

REPORT FROM THE SELECT COMMITTEE ON RAILWAYS.

Our readers are aware that the 11th clause of the Railways Bill, which was for the purpose of giving discretionary powers to the Board of Trade as to the regulation of railways, excited the greatest alarm on the part of the railway boards. Sir Robert Peel was consequently induced to move for a special committee to receive evidence as to the tendency of the proposed clause. This committee has now concluded its labours, and after a lengthened investigation has made its report. The committee after stating the arguments used on both sides, sum up by recommending that the Board of Trade should not at present have the discretionary power contemplated in the 11th clause of the Bill above quoted, and prefer that the supervision of that department should be exercised in the way of suggestion rather than in that of positive regulation. This, as it will be seen wards off the blow for another year, and we hope that the railway interest will be so far instructed by this attempt, as to take better measures to oppose any future aggression of the Board of Trade.

The evidence attached to the report contains much matter of interest to which we shall be obliged to refer in a discursive manner, but before we refer to this we feel it our duty to express the obligations which the profession owes to Brunel for the able and candid way in which he gave his evidence, throwing aside all personal considerations and feelings of partiality, uninfluenced by the blandishments of the Board of Trade, and not to be deceived by its sophistries, he boldly and unscrupulously stripped the railway department of its pretensions, and exposed the incompetency and ambition of its officers. We wish that it were in our power to give equal praise to the elder Stephenson, but with the exception of the noble tribute he gave to the merits of the Great Western railway, he presented a lamentable contrast to Brunel.—Mr. Labouchere exhibited an ability in the management of his cause, which we cannot but recognize, but we must at the same time regret that it was not exerted in a better cause.

From Mr. Laing's evidence and from the documents annexed we learn some particulars as to the constitution of the Railway Department of the Board of Trade, which as it is of some importance we have thought it desirable to notice. The Department is placed like the Statistical Department in charge of Mr. Porter, and for which he receives 200*l*. per annum extra, but it does not appear that he takes any very active part.—Lieutenant-Colonel Sir Frederic Smith is Inspector General of Railways, with a salary of 900*l*. per annum and travelling expenses while engaged out of London, but without retiring allowance. The Board of Trade observes that, "the provision of the act which excludes the appointment of any one connected with railways, and the high rate of remuneration, which would be requisite to secure the undivided services of any eminent civil engineer, are of themselves sufficient to direct and almost to restrict their Lordship's choice to some officer of the Royal Engineer corps, who has a competent practical knowledge of railways." Mr. Laing transacts the official business of the Department, and is the Law and Corresponding Clerk with a salary of 500*l*. per annum.—Mr. Porter and Mr. Laing are authorized to sign all notices, documents, &c., in the name of the Board of Trade.—Mr. Oswald acts as a junior clerk. The total expense of the establishment is estimated at 1400*l*. per annum. The engineer officers employed in the first instance to assist Sir Frederic Smith, were paid two guineas a-day and expenses. The Department is put under the superintendence of the President of the Board of Trade, as consulting member of the Board. It is in contemplation that the establishment must be slightly increased.

In the evidence of the several parties who were present at the celebrated Birmingham Conference for devising the means of preventing accidents, we learn for the first time the reason that the results were so very trifling. It seems that on discussion, the difficulties that stared them in the face as to forming any general system were so great that the attempt was given up in despair, and the parties present silently acquiesced in the resolutions, which had been prepared, at the same time recommending the regulations of the Liverpool and Manchester Railway for consideration and not for adoption. Frightened as they had been by newspaper clamour—into the endeavour to adopt some measure, they were confirmed in their original views, that as the accidents had not arisen from neglect on the part of the companies, neither yet had they sufficient experience to devise any effective remedies.

We find also some clue to the mode of proceeding of the well known committee of three, whose activity and inactivity were the [illegible] of so much alarm in the early part of the agitation. It [illegible] that when the railway body, dissatisfied with their conduct, found it necessary to take the matter into their own hands, the committee thought proper to disclaim having in any degree wished to bind the companies, a salutary step which seems to have had the best effect.—Mr. Labouchere was thus deprived of the support of this committee, whose neglect of their duties had excited so much indignation, and in place of this pliant body, he had to contend with the great railway interest, representing fifty millions of capital.

Brunel's evidence was the mainstay of the opposition, and abounds in practical information, which we wish that it was in our power to transcribe, but the limited nature of our space forbids. What he says as to engine drivers is of direct importance to the profession, and is so totally opposed to the vulgar opinion on the subject that we are compelled to insert it here.

There is another regulation suggested, and which therefore I presume is to be acted upon; it is that an engine driver shall be able to read his instructions. Now I dare say that appears to a great many gentlemen a very essential thing; but not only do I maintain that it is not essential, but I maintain that the mere laying down that rule as a rule, is a proof that the party suggesting it is not acquainted with the class of men we are dealing with, and that we must deal with, as engine drivers. I should have thought too, that Sir Frederic Smith's knowledge of the world and of military life, of privates, would have told him that the class of men who must be employed as workmen, are not a class of men who learn their instructions by reading, even if they can read; their knowledge is obtained entirely orally. A man of that class has not obtained, as we have, the power of reading and remembering what he reads. These sort of men will read and derive a little amusement from what they read, but they have not obtained the power of learning things by reading, they learn orally entirely. As to the instructions, it is true we print them, and it is true we make them read them, and we make them sign them, partly to ensure their having an opportunity to see them, but very much to satisfy the public mind when an accident has occurred; but I do not believe the men obtain the slightest knowledge of their instructions by reading; they may read them through and get up with the printed letters in their eyes, but as to obtaining information from it, they do not; they obtain their information orally; and whether a man can read his instructions or not, does not at all affect the question of his being a good engineer or not. Our very best man on the Great Western Railway, the very best engine driver we ever had; a very superior man, who is now foreman of our engineers at Reading, a man whom I trust better than anybody I have got on the line, can neither read nor write, and yet he issues instructions, and he has a clerk who writes written orders; and it would be a serious mischief if any regulation of the Legislature should deprive us of him, and of a number of others that we have. I am not one to sneer at education, but I would not give sixpence in hiring an engine man, because of his knowing how to read or write. I believe that of the two, the non-reading man is the best, and for this reason: I defy Sir Frederic Smith, or any person who has general information, and is in the habit of reading, to drive an engine. If you are going five or six miles without anything to attract attention, depend upon it you will begin thinking of something else. It is impossible that a man that indulges in reading, should make a good engine driver; it requires a species of machine, an intelligent man, an honest man, a sober man, a steady man; but I would much rather not have a thinking man. I never dare drive an engine, although I always go upon the engine; because if I go upon a bit of the line without anything to attract my attention, I begin thinking of something else. The duty of the engine man is the simplest possible thing; he must first of all have a good constitution, and be able to stand rough weather; in fact, a gentleman cannot be an engine driver, or any man who can earn a livelihood in any quiet, comfortable way; he must know something of machinery, to a very small extent; of course he must know the parts of a locomotive engine, and he must be something of a workman, although the fine workmen rarely make good engine drivers; such a very low class of knowledge of the machinery, that I can hardly call it knowledge; a mechanic learns that in a fortnight or three weeks. He must be a sober man, and have all those qualities which are included in the general term of "steady;" I hardly know how to define them; but he must be accustomed to follow orders, not desirous of infringing them; not reckless, and be what is commonly understood by "a steady man."

Sir Frederic Smith was the first witness examined, being in support of the government recommendations—what were the arguments which he used we think it unnecessary to repeat, the public being sufficiently conversant with them. He bore testimony to the harmony with which the companies and their engineers had co-operated with him, and expressed his regret at its being disturbed by the difference which had arisen on the discretionary clause—an ill omen we should say as to the result which would be likely to be realized if the clause had become the law of the land. Sir Frederic was obliged to admit that most of his proposed regulations were inapplicable as general rules, and that the greatest injustice would be the effect of their stringent execution. It must be observed that the intended legislation would have authorized the Board of Trade to interfere with the traffic in many annoying ways, as for instance on the Manchester and Leeds railway, suppressing the mixed train, disturbing the arrangements of lines generally by prescribing an interval between the trains, regulating the speed and the load, crushing small companies by overburthening them with expenses, increasing the police, brakesmen, number of breaks, buffer springs, preventing assistant engines from pushing behind, carrying luggage with passengers, obliging to work by time tables.

Mr. Booth, of the Liverpool and Manchester Railway exhibited his usual acquaintance with the subject, and expressed in the strongest terms his objections to the powers proposed to be given to the Board of Trade. He unequivocally stated that he did not consider any central authority or Board competent, in the present state of knowledge as referrible to railways, to take on itself the issuing of regulations. Mr. Booth, as well as the other witnesses who followed on the same side, forcibly dwelt on the melancholy consequences which must ensue from divided responsibility, and showed the injustice of allowing the Board of Trade to make rules, and then punishing the companies for the bad working of them. For a central authority to attempt to regulate the traffic on the Liverpool and Manchester would be productive of the greatest confusion and injustice, on account of the fluctuating nature of the traffic, requiring that arrangements should be made at the moment to conform to it. In appealing against the recommendations already made by the Board of Trade authorities, Mr. Booth forcibly urged that they were such as to show that they had not that experience which is necessary to make them capable of issuing regulations, and that he could not have confidence as to their general discretion in issuing regulations. The proposed fifteen minutes interval between the trains, he showed to be equal on his line to a distance of seven miles. Mr. Booth attributed in some measure the success of the Liverpool and Manchester Railway in escaping accidents to the very great traffic, which obliged every engine driver to be constantly on the alert. Very few accidents, observed he, occur in crossing Cheapside for example; every body is obliged to be on the alert, and, to look about him.—The proposed regulation as to ballast trains he showed would be absolutely impracticable, and time tables equally useless and mischievous. The propriety of leaving the responsibility with the companies, was supported by their witnesses on the ground that they had a stronger pecuniary interest in the safety of passengers, and prevention of accidents than any other parties, and were of course urged to adopt every possible precaution. One company was mentioned as having lost £10,000 by a single accident.

Brunel, whose examination occupied two days, followed in support of Mr. Booth. To the spirit which characterized his examination we have already referred. He expressed more strongly even than Mr. Booth his want of confidence in the officers of the Board of Trade generally and individually, and throughout his examination kept Mr. Labouchere's vigilance fully on the alert, frequently discomfiting him in his attempts to entrap him into a toleration of the interference of the Board, to which Brunel objected *in toto*. Upon the causes of accidents, the remarks of this engineer fully bear out the views which we maintained both on this and the steam vessel question, and are well worthy of perusal.

I think the officers of the Board of Trade are under a completely erroneous impression both of the circumstances which really lead to those accidents, and of the best mode of remedying them, and that they are without, and must always be without, any sufficient knowledge of the practical working of the system with which they propose to interfere; and I think that the accidents and the suggestions arising from those accidents themselves, prove what I assert. They certainly prove it to the minds of those who are familiar with the practical working of railways. I dare say it will be difficult to prove that satisfactorily to the Committee, from the very circumstance I have just mentioned, that they are not acquainted with the practical detail of the working; but still, if the Committee will allow me, I will attempt it. I think that the mere circumstance of which the officers who have been appointed have themselves given very strong evidence, namely, that notwithstanding the tremendous speed at which railway travelling is carried on, notwithstanding the appearance of almost trusting to Providence as we run along the lines, and the apparently great risks that are run, that notwithstanding all this, it is a notorious fact, and one which is admitted by the officers who have inspected railways, that it is a safer mode of travelling than any other adopted up to the present time; and that, notwithstanding all those apparent dangers, really there is very little danger comparatively: I think that ought to have led them to consider, that, in all probability, the dangers that still exist, do not arise from any glaring prominent defects in the system, which of course those who have brought it to this state of perfection must long since have seen, and that it would hardly be left to those officers to whom the thing must be new, to discover suddenly that we have passed over some of the most prominent and easily removed causes of danger; and I think that, as they become more intimate with the practical working of railways, they will see that the real cause of danger, small as it now is, consists of a multitude of small operating causes, which occasionally and accidentally are all brought to bear, and all operate to produce risk. But the real source of the danger, and the only one which there is any hope of removing, is in a complication of imperfections in a great number of the mechanical parts of the system. We have gradually discovered, that the wheels had better be a little wider in gauge than we made them at first; that they had better not be quite so narrest in the external gauge; that they should be about half an inch wider on the tire; that the guard-rails had better not touch them; that increased care should be given to the gauge of the rail; and that the tail-lamps must be put in a position in which they shall be less likely to be obscured. A number of small things of that sort are gradually discovered, generally speaking, without any serious accident; they are gradually discovered and removed; and thus the original chances of risk are diminished, till, in fact, they do not occur. All those who are familiar with the working of a railway, or with the manufacture of any article, or with the progress of any complicated system of that sort, well know that it is in vain to attempt to make workmen more perfect; it is in vain to attempt to trust to any regulations in such a manner as to expect, that when a new accident occurs, they shall all apply; and that it is still more vain to expect, that they will be all obeyed. It is by gradual and progressive improvements, in all the little details, that the risk of accident is diminished; and it is by that alone that the risk of danger will be removed. This is familiar to us, and to the persons working the railways; but I am sure it cannot have struck the gentlemen who have been sent to inspect the railways; because, first of all, no looking on occasionally will make them acquainted with that which we only learn by seeing it, and feeling it, and feeling the inconvenience of it every day. They also cannot learn it, because we keep progressing so fast, that the knowledge of one day will not apply to the next; and although their own suggestions which they have made after those accidents, and although the reports which have been made by several of them show very great investigation, and a very acute perception of the circumstances, which they happened to be able to lay hold of on the ground after the accidents had occurred, still those suggestions show that they are aiming simply at that which we know cannot be attained, namely, at perfection in the regulations and in the character of the men that we have to employ, and that it is by attention to the multitude of little details alone, that approximation to perfection can be attained; that that is their view, is evident also, from the suggestions which they have all thrown out after seeing those accidents.

Mr. Brunel remarks on the application of two engines in conjunction.

All chances of collision of course are got rid of between those trains, and the average power of the whole is better obtained; although there again the necessity of understanding exactly the practical operation of the thing is evident, because it is not the case that two engines, when coupled together and drawing a load, will do twice as much as one engine. It is rather a curious circumstance, but I mean to say that the average power of the engines is best obtained by putting them together, if we take into consideration the chances of one engine running a little dry, or of any circumstance occurring to lessen the power of one engine, we do then get the average power of two or three better by sending them together than by sending them separately; and I have no hesitation in saying, that the general rule ought rather to be (though I think it would be bad to have any rule either way) to send them altogether than to send them in trains, each consisting of a single engine.

We are restricted by the space devoted to other objects from giving any greater length to the discussion of this report, and we must leave it congratulating engineers on this partial triumph, obtained at the last hour. We do sincerely trust that it will be a warning to make every exertion on the other questions that are likely to be agitated. Let a stand of this kind be made against the Ten Per Cent. Deposit Clause, let a committee be got on this question, and a relief much wanted will we hope be obtained. In concluding these remarks, we should be guilty of injustice if we did not notice the ability of Mr. Saunder's evidence, and express the great obligations the railways must entertain to Sir Robert Peel for his timely interference. The fairness shown by this statesman on this occasion will we hope prove an encouragement for obtaining a repeal of the obnoxious Ten Per Cent. Clause, as it affords a promise of our obtaining aid, if we do but show a fair case.

NEW AND USEFUL INVENTIONS.—No. 5.

By Philotechnicos.

Patent Decorative Carving and Sculpture Works, Ranelagh Road, Thames Bank, Pimlico.

This invention presents one of those great strides of machinery with which the present day abounds, for superseding manual labour in works of art as well as science. What would our forefathers have said at hearing that carving was to be done by machinery; the idea would have been considered preposterous, and the inventor, at least, a madman; but now it is almost received as a matter of course, and nothing is thought impossible; it is, moreover, most remarkable, that some of these valuable inventions are mere improvements upon simple inventions and schemes of ancient date, and familiar to nearly every one. Who would have thought that the common marking iron, used for stamping or burning the initial or name of the owner on implements of trade, should give the idea of a similar process for a more elaborate purpose—that of carving (if the term can be used) in wood? but so it is—or at least such is my anticipation from its proximity, which the reader may judge of from the description of the method adopted for the patent carving. An iron mould is first cast from a plaster or wood model. The iron mould is heated to a red heat, and applied to a piece of wood, previously damped, with great force, and repeated, until the wood is burnt to the required form. The char is then cleaned off, and any undercutting that may be required done by hand; when the operation is finished it has the appearance of old oak. The surface may be brought almost to a polish, when it assumes a highly finished appearance, nearly equal to the original, though of a first-rate master, from which it was copied. By the great pressure to which the wood is subjected, it is rendered much harder, and is consequently more secure against the action of the atmosphere or insects. The immense uses to which the patent carving can be applied must be obvious to all, and needs but little description; and will afford another opportunity—which I am always glad to give the hint of—to the "Commissioners for Building New Churches," to enliven their "interiors," which now present nothing but naked roofs, plain panellings, and any thing but gothic finishings. How does my imagination brighten at the prospect! seats, "as of old," with their beautifully carved finial standards—pulpits paneled and moulded to richness—gallery fronts with elaborately carved tablets from scriptural subjects—the altar-piece beautifully ornamented with canopies, crockets, and finials—the roof with rich tracery, bosses, queer-looking heads, cherubim and pendants—the pew enclosures (if any, as I hope, ere long, to see the present kind entirely abandoned, as in that neat little chapel of St. Katherine in the Regent's Park, where the body of the church contains none of those pen-like objects,) I should desire to see enlivened by the beauties of gothic carving—the communion table, chairs and enclosure, oh, what beautiful objects! elaborate to a degree; carved legs, carved backs, carved balusters—the organ, a gem, a specimen of Gibbons, with that fine, dark, brilliant polish sometimes seen in churches of the olden time. But where does my imagination lead me? were it of use to prophecy, to write, to agitate, I would do so with abundant pleasure; but I fear all the labour would be lost, all my advice thrown away, and all my time and research only wasted upon the desert air, ere they, the said Commissioners, will take the hint upon such a subject; but if they will not, surely the profession have some little influence, and will do their best to enhance the interest of our modern churches; 'tis to them I appeal, and earnestly solicit their support, in the introduction of such ornament as will display their taste and judgment, and give good scope for ingenuity. The patent carving bids fair to accomplish this, as the price—the iron ruler of all architecture—is so considerably less than that of real carving—about one third, and, in many cases one fifth of its cost.

This invention is admirably adapted to the styles now so much in vogue, the Renaissance, Elizabethan, and Italian, the enrichments of which being so frequently repeated, make the cost of the original mould comparatively small; for upon repetition mainly depends the saving of expense. Articles of furniture are famous subjects upon which these magical operations may be performed; those old fashioned, comfortable-looking, high-backed, walnut tree chairs, with their crimson plushed seats and grotesque-looking ornaments, may be imitated to correctness. Cabinets—the pride of former days, with all their twistings and turnings, can be done with facility, and the work of years performed in as many days. It is needless to enumerate the very many purposes to which the patent process can be applied; suffice it to say, that any work carved in wood or moulded in plaster can be executed by its pyrotechnic influence, save and except the undercutting, which must be, as before stated, finished by hand. A tablet in which figures appear of cupids in high relief, is exhibited at the works, and proves full well the triumphal power of the process; and a medallion portrait of the Duke of Wellington, presented to me as a specimen, shows its use in that department.

Patent Anti-Corrosive Iron Tube Works, Brunswick Street, Blackfriars Road.

These tubes are of wrought iron tinned inside and outside, and are used for gas, steam, or water. The process renders them almost impenetrable to corrosion, and causes them to resist the action of gas or acids, for a much longer period than the common tubes; they are useful to brewers, distillers, operative chemists, and other manufacturers, and for the water companies they would be excellent, on account of the purity of the tin with which they are coated,—they are well adapted for service pipes, being less liable to burst by frost than their softer rivals.

ON THE HISTORY OF ANTIQUITIES.

SIR—The subject of the antiquities of those nations which occupied an early period of history, has frequently attracted the attention of men of learning, who have examined with the greatest care every record which could throw light on the subject of their inquiry.

These inquiries, however, have been always entered into in detached portions for the purpose of studying the history and antiquities of a single nation, and for that reason though they have been made by persons well qualified for the task, their efforts have been to a great extent fruitless, and it yet remains to collect into one focus the result of their separate labours, and by affording the opportunity for comparison to increase their value tenfold. Since the principal records of the periods to which I allude, consist in remains of the useful or liberal arts, such a comparison alone can at all exhibit the influence one nation has had on another in the progress of civilization, and enable us to connect many hitherto detached passages in the history of the arts.

No one has, perhaps, carefully compared the remains of ancient art to be found in Egypt, India, Etruria and Peru, yet we have some grounds for supposing that there has been a connection more or less close between the inhabitants of all those countries: in fact to go deeply into all these histories, by a personal examination of the principal remains, would be too arduous a task for any one individual. Besides the nations before mentioned, an attempt of this kind would embrace the history of the Chaldees, the early history of the Tartars, the Scandinavian tribes, the originators of Stonehenge, and the various constructions called Cyclopean, with the remains of now unknown origin in America, which have lately attracted the attention of the antiquaries of that continent.

Another branch of the same subject intimately connected with the former, and of which the importance is too obvious to require explanation, is that of inscriptions; and I have great reason to think that in this especially, our present ignorance arises rather from the want of a skilful combination of acquired materials, than from a deficiency in those materials themselves.

On these accounts I am ready to believe that any one entering upon this subject and fully carrying it out, (and its comprehensiveness would be its excellence), would confer an important benefit on art and literature.

I remain, &c.

E. L.

ON CONTRACTS.

SIR—I shall feel particularly obliged if you will be pleased to give your opinion, in your next publication, on the question given below, as it will be of great service in guiding me upon the business.

I remain, your most obliged,

7, *May*, M. R.

(CASE.)

I have been employed in making designs for a Rectory House, and afterwards a specification of the several works, and a very full detailed estimate of every item of expense of building the same, to accompany the specification. Among other things contained in the specification was the sinking of a well (that a well should be sunk to a sufficient depth to obtain water), and in the detailed estimate was an item for sinking the well of 3*l.* 10*s.*, as being informed by the Incumbent that the springs were very near the surface (which they are in the adjoining fields), and in the specification in the general condition is the following clause, that all extras, additions, or deductions made to the building shall be measured and valued according to the detailed estimate accompanying the specification. Now the site of the house is an eminence on the limestone stratum, and I have sunk a well to the depth of 78 feet below the surface, without any chance or sign of obtaining water, at an additional expense of 20*l.* over the 3*l.* 10*s.* allowed in the detailed estimate, (which sum I have not made a claim for). Through there being no water the Incumbent will not certify that the contract is fulfilled.—Please to state your opinion on the above.

[We are of opinion that from the wording of the specification alone, that the contractor has not strictly fulfilled the conditions of his contract in the eye of the law; it is one of those foolish unlimited stipulations we see too often inserted in specifications. The specification should have stated not exceeding a certain depth. However, if it can be clearly proved that the Incumbent held out to the parties tendering, that water could be procured near the surface, with a view that such parties should imagine it to be the case, and put down a price accordingly; we are then of opinion that the contractor would be relieved in equity, particularly if he proved that he had sunk the well to a reasonable depth, to show that he had used his best endeavours to procure water—which in the present case we are of opinio[n he] has done.]—EDITOR.

A Summer's Day at Windsor, and a Visit to Eton. By Edward Jesse. London, 1841. Murray.

As a guide-book or manual for the information of those who visit Windsor Castle and its immediate vicinity, this may fairly be styled a superior volume of the kind, it being tastefully got up, and containing several well-executed wood-cuts. That the subjects of the latter are well chosen, and thereby enhance the interest of the book, is more than we can add; for, with the exception of the frontispiece, which is a very useful situation's-plan of the castle, the print showing, in elevation, two bays of the exterior of St. George's chapel, another showing three ditto of the Tomb House, and one or two other cuts, the rest of the illustrations illustrate nothing. Sure we are, that had they not been given, no one would ever have missed such things as portraits of trees, facsimiles of prisoner's hand-writings, the ladies and gentlemen on horseback intended to represent Her Majesty with Melbourne & Co., or the very queer old-fashioned set-out of George III. at the Eton Montem. Of the castle itself—which it may be presumed is, after all, the principal of the lions at Windsor, nothing is shown beyond the Norman gateway—which conveys no idea whatever of the exterior generally—and St. George's Hall, and the Guard Chamber, which last is executed in a most disagreeably hard manner. Surely one or two more interiors might have been introduced; we do not say that such subjects can be furnished as cheaply as representations of stumps of old trees, &c.; we would gladly give every one of the latter for a single illustration of the other kind. While Mr. Jesse affects to entertain the highest respect for Sir Jeffry Wyatville, it is certainly no very great compliment towards that architect to keep him and his work as much in the background as possible—or, rather, to keep them quite out of sight. As regards the Castle in its present state, the letterpress is as unsatisfactory as the illustrations, there being very little indeed on the subject of the building, nothing amounting to opinion, while the description is excessively meagre; we have met with very much more from time to time in periodicals and newspapers. But the hundred and fifty pages must, of course, be filled with something, and so, indeed, they are, namely, with what has been given a hundred times before in various publications—a history of the Castle, interlarded with anecdotes as trivial as they are stale. In fact, the whole is a mere "cram,"—such a production as could have been executed by any journeyman bookseller. It is one of those things which are made to sell, for the same reason that other guide-books sell, and that court calendars find customers. But as the title-page bears a name, we naturally—and, as it now turns out, foolishly—expected to meet with something above the ordinary run of such performances. What Mr. Jesse may be as a naturalist we know not; but here he exhibits himself as a bookmaker, one of those whom Carlyle very unceremoniously calls "respectable literary thieves and paupers."

The Decorator and Artist's Assistant. Edited by J. PAGE, Author of the Acanthus.

The appearance of this periodical work is, we trust, a proof of increasing taste for design, and viewed in such a light, it meets with our best wishes. Published in weekly numbers at sixpence, and monthly parts at two shillings, it contains a variety of designs for architectural ornaments, furniture, jewellery, &c., and will no doubt be extensively patronized by the artisans to whom it is addressed. We wish that Mr. Page would in every instance give the authorities of the designs which he inserts, by which their value would be much enhanced. There is a want of boldness in the outlines, but as that is attributable to the etching, we cannot object to it.

The Acanthus.

As a homage to the architectural profession we present to their notice Mr. Page's Plate of the Acanthus, designed, drawn and engraved by himself. Mr. Page is, we believe, a self-taught artist, and we know him to be meritorious and hardworking; we hope therefore these will be claims to the patronage of the profession for which he has shown so much respect. As an object of study the luxuriant plant depicted in this engraving will well repay the student who lays out his half-crown upon it. It is a cheap and elegant ornament for the portfolio. We are informed that the drawing obtained a gold medal at the Society of Arts.

We have been obliged to defer our farther notice of Mr. Clegg's "Practical Manufacture and Distribution of Coal Gas," until next month.

PAPERS ON HARBOURS AND RIVERS.

Report on the navigation of the Forth. By Robert Stevenson & Sons, Civil Engineers.

Prefatory Note.—Having been called upon, by the magistrates of Stirling, to revise, with a view to its being printed, the following Report, which was made as far back as 1828, we have done so with much care. It affords us great satisfaction to be enabled to state, that the views contained in the Report have derived additional confirmation from our past experience, more especially in the case of the River Tay, whose navigation was formerly obstructed by obstacles which, although composed of different materials, closely resemble, in their position and extent, those which at present hinder the advancement of the trade of the Forth. By the partial removal of the various fords, the depth of water in the Tay, at spring tides, has been increased from 11 feet 9 inches to 16 feet; and the works, which are not yet completed, have occupied little more than two years. The hardness of the materials which compose the Fords of the Forth may render their removal more tedious; but it ought not to be forgotten, that it, at the same time, ensures greater permanency in the form of the excavated channel. It is therefore with increased confidence that we repeat the recommendations of the Report of 1828.

ROBERT STEVENSON & SONS.

Edinburgh, Dec. 10, 1838.

The Firth and River Forth are navigable for the largest class of merchant vessels, as high as the port of Alloa; and in spring tides, vessels drawing 9 feet water may proceed to Stirling, lying 10½ miles above Alloa, while those drawing 7½ feet water, may reach the mills of Craigforth, 5 miles above Stirling. The improvement of the navigation between Alloa and Stirling, has long been regarded as a desirable object, and was brought under the notice of the Reporter by the magistrates of Stirling, in the month of November, 1825, when it was proposed to petition Parliament for leave to bring in a bill for this measure. * *

Above Alloa the river becomes very circuitous. By the navigation the distance from thence to Stirling is 10½ miles, while in a direct line it measures only 5 miles. It has been proposed to render the navigation of this part of the river more direct, by cutting through the links, or peninsular necks of land, for which the track of this river is so remarkable. This would shorten the navigable track; but it would have a direct tendency to deteriorate the navigation below, as a great volume of the tidal water, which at present passes over and scours the lower banks four times in the twenty-four hours, would be cut off and diverted from its course. The cutting of the links and straightening the river would also, in a material degree, interfere with the vested rights of the proprietors of the banks, by depriving some of the benefit of a water communication, and destroying the valuable salmon fisheries of others. This plan, therefore, though worthy of consideration, is, upon the whole, judged inexpedient in the existing state of things. The Reporter proposes to improve the present channel of the river by deepening it, and removing part of the numerous obstructions called Fords, and he therefore now proceeds to describe in detail each of these obstructions, and the works which are considered necessary for their removal.

Between Alloa and Stirling there are seven principal fords, or shallow parts of the river, which form so many obstructions to the navigation. It is not believed that incumbrances of a similar geological structure are to be met with in almost any other river in the kingdom. The Firths of Tay, Moray, Clyde, Solway, and the Rivers Mersey, Severn, Thames, and Humber, have their peculiar tides and difficulties, both in the form of rocks and sand banks, but none of these channels are impeded by successive chains of imbedded stones and rocks, appearing at low water, like those called the Fords of Stirling. Various hypotheses have been started to account for the existence of these fords. Some have supposed them to be artificial, arising from stones having been thrown into the shallowest parts of the river at an early period, to render it fordable for cattle. But from the minute examination which the progress of this survey has enabled the reporter to make, he has no hesitation in stating, that they are natural barriers of rock traversing the valley of the Forth, and are what geologists term *whin-dykes*, which, from the continued scouring of the bed of the river, have assumed the irregular appearance now presented by them at low water. Similar formations of whin or greenstone rock occur

of the Abbey Craig, and also on the northern side

The fords, like the cliffs at these places, consist of stones, varying in size from a cubic foot to a cubic yard, imbedded in rock. The joint effect of the crooked channel of obstructions caused by the fords, produces a great retardation in the velocity of the flood, which, in the upper parts of the river, is very sensibly less than that of the flood in the Firth, and travels at the rate of only one mile in five minutes. Although this retardation may be considered to be in part due to the operation of the river current, yet it is obvious, from its languor, that this cannot be the principal cause, and it is therefore to be sought for chiefly in the obstructions offered by the fords. On the days of new and full moon, it is high water at Alloa Pier at four hours and forty minutes; at Tullibody Pier at five hours and ten minutes; at Powis Hole at five hours and ten minutes; and at five hours and ten minutes at Stirling Shore or Quay. The consequence is, that the tide does not attain its maximum height at these three last places, until it has been ebb tide for half an hour at Alloa. It appears further, from this train of observation, that the perpendicular rise of spring tides at Alloa, is about 19 ft. 4 in.; at Tullibody, 16½ feet; at Powis Hole, 12 feet; and at Stirling, 7 ft. 8 in.; while the corresponding rise of neap tides at these stations is respectively 14½ feet, 11½ feet, 7 feet, and 3 feet. There being, therefore, a rise of 19 ft. 4 in. in spring tides at Alloa, and only 7 ft. 8 in. at Stirling, the available depth at that place is less than it would have been had there been no rise on the bed of the river, by 11 ft. 8 in. Before leaving the subject of the tides, it may be proper to remark, that the maximum point of high water at Alloa Pier is 4 inches above the level of the high water at Tullibody Pier, while it is 2 inches lower at Powis Hole, and 3½ inches higher at Stirling Shore.

The great object, therefore to which the reporter would direct the exertions of the Magistrates of Stirling, as Conservators of the Navigation of the Forth, is to the removal of the Fords, which are the chief obstructions to the free passage of the tide waters. The advantage of deepening the bottom in the upper reaches of the river is obvious, as the natural effect of such a change is to permit the tide to flow over the lowered ridges at an earlier period of the tide, and thus to allow high water to take place sooner, before the tide below may have fallen to any considerable extent; while, at the same time, an increased depth is obtained. Vessels may then start from Alloa earlier in the flood-tide, and reach the shallowest parts of the river, near Stirling, at the top of high water. In this view of the method of improving this part of the navigation, it is very satisfactory to know, that a navigable track through the whole of these obstructions may be formed at a comparatively small expense, by the common and simple process of blasting with gunpowder, and the use of flats or lighters fitted with cranes and other apparatus. The Reporter will now describe, in detail, the extent of the operations he considers necessary at the different fords.

On the reach between Alloa and Throsk, he proposes that a buoy, provided with suitable moorings, should be laid down at the seaward extremity of the bank, on the eastern side of Alloa Island, about a quarter of a mile above Alloa Pier. This buoy will be useful as a direction for avoiding an extensive spit of sand, on either side of that island. On its western side a perch or beacon is to be erected as a further guide for that channel.

The commencement of Throsk Ford is about a mile and a quarter above Alloa Pier. The channel on this ford is very shallow, and when the river is in its state of summer water, it dries nearly all the way across; but as this part of the river has the advantage of a perpendicular rise of about 18 feet in spring tides, and 13½ feet in neap tides, the navigation is comparatively little impeded. On referring to the plan and longitudinal section of the river, it will be seen, by the parts coloured red, that little excavation is proposed here. A buoy, however, is intended to be moored in a central position to show the deepest water, and, as a farther direction, a perch is to be erected on the starboard hand. This perch will also serve to point out the proper channel for passing Tullibody Island.

Cambus Ford is about a mile and a quarter above Throsk. The bottom of the channel towards the lower end of this ford consists of large stones and roots of trees, and in its upper part, large boulder stones appear above the surface at low water. The rise of tide at this ford is 16½ feet in spring tides, and 11½ feet in neap tides. The navigable channel to be cleared measures about 500 yards in length, and 30 yards in breadth at the bottom. An average cutting of one foot in depth will give about 20 feet at high water of spring tides at this place. A perch is to be erected on the larboard hand, opposite Tullibody Yare or Pier, and another on the starboard hand, to the westward of the Mouth of the Devon. By this means vessels will be enabled to avoid the foul ground at the bank on the opposite side of the river. The track of Cambus Ford is so obvious, that it is not considered necessary to moor a buoy to point out the deepest channel.

Badneath Ford is about three quarters of a mile above Cambus. Its bottom consists of two irregular lines of boulder stones, crossing the bed of the river with numerous detached masses of the same description. From the winding direction of the channel at this place, the navigation is rendered more difficult than at either of the fords below; and, in clearing it, considerable works of excavation will be required. In spring tides the rise of the water at the lower end of this ford is 16 ft. 6 in., and at the upper end 13 ft. 4 in.; there is therefore a fall of 3 ft. 2 in., on a length of about 1150 yards, which occasions a rapid at low water, when the river is in its summer state. In neap tides, the rise is about 11 ft. 2 in. at the lower end, and 8 feet at the upper end. The length of the channel intended to be excavated at this ford is about 666 yards, and its breadth will, as already proposed, be 30 yards at the bottom. An average depth of cutting over its whole extent of about one foot will be required in order to give a depth of 18 feet at high water of spring tides. A perch is to be placed on the larboard hand at the lower end of this ford, and a buoy at the upper end. A perch must also be placed at Fallin Point on the larboard hand. In passing Polmaise and Scobbie's Pow, no difficulty occurs; near Bannockburn, however, there is a bank where a perch will be required as a direction for the deepest channel.

Manor Ford, about two miles and a quarter above Bandeath, has an irregular and stoney bottom. At the lower end of this ford, the rise in spring tides is 13 ft. 8 in., and at the upper end 12 ft. 6 in.; and in neap tides about 8 feet and 6 ft. 10 in. respectively; there is consequently a fall at low water of 14 inches which occurs on a length of 666 yards, and produces a considerable rapid at this place. The extent of ford proposed to be cleared measures about 666 yards in length, and the breadth and depth of the channel to be formed will be the same as that already specified. This will require an average cutting of 18 inches in depth. From the curved form of this channel, a perch will require to be laid down on the larboard side, for each end of the ford, and a buoy must be moored in a central position on the starboard hand.

The Sow Ford is about three quarters of a mile above the Manor Ford, the bottom is stoney and irregular, and its direction also forms a curved line, but as the bottom presents fewer obstructions to the current than the two fords immediately below, there is no visible rapid at this place. Spring tides here give a rise of 11 ft. 9 in., and neap tides 6 ft. 9 in. It will be seen, on referring to the plan and section that the works of excavation at the Sow Ford are not extensive. Instead of mooring buoys to point out the direction of the deepest water, it is proposed to erect two perches, the one on the starboard and the other upon the larboard hand. Wherever perches can be introduced they are considered preferable to buoys, which are more expensive both in their first cost and future maintenance.

The Abbey Ford is situate about a mile above the Sow Ford, and has already been excavated to a limited extent with a view to its improvement; but the excavation wants extension, both in breadth and in depth, to render it useful. The current here is still so much obstructed that it causes a considerable rapid when the river is in its summer state; the fall being no less than 2 ft. 6 in., on an extent of about 500 yards. Spring tides rise, at the lower end of this ford, 11 ft. 6 in., and at the upper end only 9 feet; and neap tides rise 6 ft. 9 in. at the bottom, and 4 ft. 3 in. at the top. The length of the excavation will be about 565 yards, with a breadth of 30 yards, similar to that of the other fords. The average depth of excavation, in order to obtain 13 feet at high water of spring tides, will be about 2 feet. Connected with this ford, two buoys are proposed to be moored on the larboard hand, the one at the lower, and the other at the upper extremity of the ford; and a perch must also be erected on the starboard hand.

The Town's Ford is situate about 500 yards above the Abbey Ford. The foul ground at this place extends about 1000 yards in length, and the works of excavation, in obtaining a navigable track, similar to that of the other fords, will be proportionally more extensive. Spring tides rise only 7 ft. 8 in. at the Town's Ford, and neap tides about 3 feet. Its bottom is very irregular and rocky, forming a great obstruction to the trade of the town, and the navigation of the upper parts of the river. The average depth of cutting at this ford will be 2 feet. For pointing out the deepest water of the new channel which it is intended to excavate, three buoys upon the larboard hand are considered necessary.

The results of the operations which the Reporter has described will be to deepen the river at those points where the obstructions occur; and the depths which are intended to be obtained at high water of spring tides are as follows at the various fords, viz.:—Throsk Ford, 22 feet; Cambus Ford, 20 feet; Bandeath Ford, 18 feet; Manor Ford, 16 feet; Sow Ford, 15 feet; Abbey Ford, 13 feet; Town's Ford, 13 feet.

By thus proportioning the depths at high water on each ford to its distance from Stirling, it is expected that vessels drawing 13 feet will have sufficient water over the lower fords at any period of flood, and will thus be enabled to reach Stirling at the very top of high water, and get the full advantage of the most favourable time of tide in the shallowest parts of the river.

The shore, or quay of Stirling, extends 200 feet or thereby along the right bank of the river, and consists of a breast-wall built in a rude manner with boulder stones, without the usual and necessary provision of defenders or wooden stretchers to prevent vessels from receiving injury while lying at their moorings. Vessels must consequently lie off in the stream to the great inconvenience of the mariner and trader. In any improvement, therefore, upon the navigation of the river, the unserviceable state of the quay-wall at Stirling should not be forgotten; but measures should be taken for rebuilding it, at least to some extent. The accommodation on this wharf is also very circumscribed and defective, but it may easily be extended and improved, as proposed to the Magistrates by the Reporter some years since. The road from the shore should also be formed on a more easy line of draught. It would likewise prove a great convenience to the southern parts of the town and the lower districts of the county, if an additional wharf, and a road from thence, were formed about the central part of the Town's Ford; as also proposed in the report above alluded to. In conclusion, the Reporter has to state as the general result of his inquiry, that it appears, from the annexed estimate, that by an expenditure of about £10,126 4s. the fords of the Forth might be cleared, so as in spring tides to admit the passage up to Stirling of the ordinary class of merchant vessels drawing about 13 feet water; and he cannot but think the importance of such an improvement far outweighs the capital required for its attainment. The position and rising importance of Stirling is too obvious to be longer neglected. It is the natural emporium of the Western Highlands, and lies in front of an extensive and fertile district, containing many valuable waterfalls and other facilities for the establishment of large manufactories.

ROBERT STEVENSON.

Abstract estimate of the probable expense of the works of excavation, mooring buoys, and erecting perches or beacons in the several fords and reaches, on the river Forth, between Alloa and Stirling, agreeably to the foregoing report.

	£	s.	d.
For the expense of works of excavation and removal of stuff, and for mooring a buoy and erecting a perch connected with the reach between Alloa and Throsk, - - -	£ 72	1	0
For works of excavation, &c., at Cambus Ford -	618	18	0

"ON THE IMPROVEMENT OF RIVERS, &c."

SIR—In your review last month of my Treatise on the Improvement of the Navigation of Rivers, you have given an entirely erroneous version of my views, by an unfortunate mal-arrangement of your quotations. This has possibly arisen in the press, nevertheless every scientific or practical man must feel bound, after merely reading your review, to pronounce the work quite undeserving of the approbation with which you and other literary characters have been pleased to honour it.

In chapter 2, is my definition of the regimen, or state of those rivers which are free from bars, and the plain inference to be drawn from this chapter alone must be, inasmuch as "like causes produce like effects," that we can only ensure the improvement of defective, or bar rivers, by approximating their condition to that of those which are in the required state.

In chapter 3, I give a representation of those features of the regimen, or state of bar rivers, which mark the difference between them and those which are free from bars.

In chapter 7, "*on the course to be adopted for the improvement of the depth on the bars of rivers, and in their channels*," I state, "the reasoning in the preceding pages on the causes of the formation of bars, suggests the course to be adopted for their amelioration, by the removal of all those inner banks, or shoals, stretching like dams across the river, which have the effect of preventing the rapid discharge of the backwater during the proper tidal duration of the ebb."

Again, "seeing that the existence of bars is to be attributed to the too great declivity of the bed of the river, or to that of its low water surface, the impropriety of forming dams across a tidal river, with the view of converting it into a line of navigation by the means of locks, ought to strike every reflecting mind as a measure which should never be adopted when there exists any possibility of obtaining the requisite depth of water by deepening the bed of the river."

In lieu of giving the above, you have merely quoted as my means of improvement, a case or exception, in which I have supposed the existence of impediments to carrying the preceding views into execution, such as the great expense of lowering a long length of rocky bed, which expense the trade of the port might not be able to bear.

Considering the error into which you have been misled, by forming your opinion upon the excepted case, in lieu of the general rule which I have advanced, I am not surprised that your views of the utility of my theory do not coincide with the favourable opinions it has elicited from other scientific quarters.

In my account of the former theories on the cause of the formation of bars, I have given the names of every author who to my knowledge has advanced upon the subject any thing beyond the opinions generally held. I did not give the name of the author of the fourth theory, because my quotation is only from a paper signed Nauticus, in the Nautical Magazine for 1837, page 487; a work much used for the diffusion of information connected with hydraulic engineering.

I perceive in your May number that Mr. Henry Barrett avows himself the author of the paper signed Nauticus.

Mr. Barrett also takes credit to himself as the originator of the suggestion of the "formation of harbours with double entrances," a principle which he says, "is now recommended by the commissioners in their report of a survey of the harbours on the south east coast." But there is no piracy of Mr. Barrett's conceptions in this, inasmuch as harbours with double entrances have been in existence for many centuries; neither is there any resemblance between the *boná fide* harbours of refuge proposed by the Government Commissioners to be constructed in five fathoms at low water, upon the principle of the Plymouth or Cherbourg breakwaters, and the harbours proposed by Mr. Barrett to be constructed at Dungeness, or Lowestoffe Ness; the latter being mere inland excavations, with channels of approach to them to be cut through the drifting shingle beach; but which channels and excavations are to remain for ever afterwards clear of deposit according to the theory of their projector Mr. Barrett. In my humble opinion they would speedily fill up again and become *terra firma*, notwithstanding the double entrances. Any scientific or practical man on examining Mr. Barrett's plans for harbours, will immediately perceive the error which has been made in believing that there would be any current *through* the harbour, as this could only take place if the course from one entrance to the other, *through* the harbour, were shorter than by the coast line.

In the Nautical Magazine for 1838, page 97, is a full description of Mr. Barrett's harbours of refuge, and a reply to his theories on bars. "Lowestoffe Ness is a flat point of sand and shingle, which has been slowly but continually increasing and extending further into the sea; towards the centre of this Ness it is proposed to excavate a basin of some three acres, and it is intended to open a channel north and south into the sea on either side of the Ness. These entrances being protected with short piers, and once opened to a depth of fifteen feet at low water, (no very easy job,) are thenceforth, and for ever after, so to remain at the simple *ipse dixit* of the engineer. I doubt it; I will ask any unprejudiced person acquainted with this part of the coast, the flow of tide, and the harbours in the neighbourhood, whether it is not much more likely that it will not only be barred up, but "blocked up and lost?" But Nauticus (Mr. Barrett) says, "The sole cause of bars at the mouths of harbours is the conflicting action of effluent currents passing into the ocean at *right angles* with the shore," and in reference to this theory of Mr. Barrett, and his subsequent statement that "there is no exception to this rule to be found on the whole surface of the globe," Investigator quietly observes, "assertion is not argument, nor a reference to the maps of the world, demonstration on such a point." Investigator also calls upon Nauticus (Mr. Barrett) for the names of the scientific men who he states are converts to his theories. In Mr. Barrett's letter of the 25th ult., to give weight to his statements he also adds, "numbering as I do among converts to my *thesis*, some of the most eminent scientific and practical men of the day;" and again, in reference to his theory, "I state this from observation of more than twenty years made on harbours and bars on various parts of Europe and in Africa." Now, Mr. Editor, I repeat with Investigator, that it would be far more satisfactory to be able to reason upon facts, produced by Mr. Barrett, in lieu of loose statements, and the shadows of opponents. Without troubling Mr. Barrett to give us an account of the rivers on the coast of Africa, (though by the bye I have lately seen that an attempt has been made to get rid of the bar of the Kowie River, by giving the latter a direction at right angles into the sea, in lieu of its old oblique course, which by Mr. Barrett's theory ought not to have been attended with a bar), I will merely ask if my information be correct as to the statement, that the river Yare (with which Mr. Barrett is locally well acquainted) is now made to discharge its waters at right angles into the sea, and that the depth on its bar is much greater than at any known former period; or when it discharged its waters into the sea with an acute angle with the shore, when the navigation was nearly lost, and the inhabitants had to cut a direct channel through the dunes into the sea.

I am your obedient servant,

W. A. Brooks.

Stockton-on-Tees, June 1841.

KENT, THE ARCHITECT.

Sir—While I quite agree with Mr. East in regard to Kent's merits as an architect, I cannot help regretting that he should have slurred them over—at least, have passed over them so lightly without at all dwelling upon them, or even mentioning by name, a single building by him. I am rather surprised too, that while speaking of Kent, Mr. E. should not have taken Mr. Allan Cunningham to task, for the supercilious and even contemptous tone in which he has expressed himself of one who deservedly ranked so high in his day both as an architect and landscape gardener, in which last capacity he may be considered the father of the so-called English style of laying out pleasure grounds. A just tribute to his memory, in that character, has been paid to him by the writer of a paper on the subject of ornamental gardening in the Foreign Quarterly; of Kent's abilities as a painter, perhaps, the less that is said the better, but Holkham alone, would suffice for his architectural reputation, for though susceptible of improvement in some respects, it is incontestably one of the most complete residences in the kingdom,—a perfect model in regard to internal arrangement and convenience, and likewise elegance of style, and variety of effect. Every part of the plan is carefully studied, and every apartment is beautifully finished. Though by no means aiming at architectural decoration, the statue gallery is one of the most charming rooms I ever beheld,—of a beauty actually fascinating, and the view from the octagon tribune at either end affords a most striking scenic effect. Never have I seen a single plan of Palladio's which at all approaches that of Holkham, or I may say, which is not more or less disfigured by glaring blemishes and defects. Nevertheless, Cunningham makes no scruple of saying: "little interest attaches to a controversy about such a design: it is heavy and monotonous, and stamped with all the faults, which were many; and all the beauties which were few, of him who proudly wrote himself 'Painter, Sculptor, and Architect.' "—No doubt this is a neatly turned, antithetically pointed sentence; yet it is ungenerous and unjust, particularly when it is considered what an immense stride forward Kent took, from the clumsy and monotonous arrangements which had till then prevailed in the mode of laying out houses of that description.

Such being the case, I am surprised that Mr. East should not have instanced Holkham, as being the noblest work of its class and period in our architecture of the last century. That he is not sparing of admiration towards Kent is evident enough; but at the same time he has expressed himself in such general—or rather such exceedingly vague terms, that it is hardly possible to make out any definite meaning. Nay, he almost seems to deny Kent one of his chief merits, when he talks of his being an artist rather than an architect, since the princely residence above-mentioned is one pre-eminently marked by excellence of plan, and other strictly architectural qualities. Or shall I say that Holkham did not occur to Mr. E.'s recollection when he was writing his more florid than perspicuous eulogium? If unacquainted with what Arthur Young says of Holkham, he will doubtless thank me for pointing out to him that writer, whose Tours, though professedly agricultural, contain a very great deal also of interesting matter, relative to the mansions and seats he visited in different parts of the country,—far more indeed than is to be obtained from others who have confined their attention to buildings and collections of pictures. I may also here mention a paper exclusively on the subject of Holkham, in the fifth volume of Elmes' Annals of the Fine Arts, which may be recommended as an able piece of architectural criticism.

I remain, &c.

Z.

---

versus S. L.

When S. L. spoke of my making so free with the Professor of Architecture, it certainly looked very much as if he thought it rather a piece of presumption on my part to make any animadversions at all on opinions delivered from such an authoritative quarter. Nevertheless he now professes to wonder where I find any expression of his that seems to discountenance discussion of the opinions of public men,—in which light, I presume, the Professor of Architecture at the Royal Academy may fairly be considered, in regard to his own art, although he is not a public character in the political world. Whether it be with regard to these last alone that S. L. is ready to allow "the roughest handling," I know not; but he might perhaps have spared himself the qualifying proviso, viz., "if it be kept within the bounds of truth and reason," because it would be exceedingly difficult indeed to ascertain and lay down those bounds in a clear and satisfactory manner. I myself, for instance, should say that I did not in the slightest degree transgress them. Or, "by keeping within the bounds of truth and reason," are we to understand that we are at liberty to say only just as much and no more than will be approved of, and allowed to be perfectly reasonable, by the party animadverted upon, or by those who take just the same side of the question? In such case, I most assuredly have on many occasions shown myself to be an outrageously unreasonable sort of person;—I hope I ever shall continue to do so.

To come to something more tangible,—S. L. says he cannot see the propriety of adopting the mode suggested for Gothic windows; yet to most other persons I think it must be obvious enough, because all the objections—and I will add reasonable ones—against glazing with small *quarrels* or panes set in lead, are removed at once, and still the beauty and character of the style, as regards moulded mullions, and tracery, fully preserved. Such window may very properly be compared to an open screen,—and wherever placed, a screen of that kind may, I conceived, be described as *open*, in contradistinction from one with solid panels—though filled in with glass.

When he talks of Gothic being objected to by most persons on the score of its interfering too much with comfort, if it is to be properly treated, I must confess I do not understand him; because if "properly" treated, that style may be made to conduce quite as much to comfort and even to luxurious refinement, as any other; that is provided it be treated not only "properly" in regard to the elements and details of the style, but ably and intelligently, so as at the same time to secure all those improvements in domestic architecture we are now familiar with.—As for fac-similes of old halls and manor houses, I would leave them to such fac-simile people as would relish a Gothic dinner off the wooden trenchers of the good old times. Most assuredly, George IV., who was supposed to be as studious of personal comfort and convenience as any gentleman need be, was not one of the persons alluded to by S. L.; otherwise he would have had modern sash windows put into all the private apartments of Windsor Castle.

S. L. still insists that *invention* is the *object* of the architect when he employs either the Grecian or Roman style, though he allows—perhaps upon downright compulsion, that originality is not always the result. Nevertheless it would certainly appear that *direct imitation* is not generally aimed at; or shall we say that the numerous modern copies of ancient porticos we have beheld of late years, are so many proofs of invention though unluckily no originality has ensued from it? As for the originality of St. Stephen's, Walbrook—I am S. L.'s most humble servant, but he really must excuse my admiring it. I am aware that to extol it, is perfectly orthodox; yet it never was my doxy, nor was it that of Dr. Anderson, who has given it the "roughest handling" imaginable in his Essay. With regard again to the spire of Bow Church, I admit it to be original enough—as unlike any thing in classical architecture as possible; still it is no favourite of mine; nor is it worthy of being put into competition with that of St. George's, Bloomsbury, which last I will boldly assert to be by far the finest composition of the kind in the metropolis—I might say in England; nor am I altogether solitary in this opinion, having heard nearly the same opinion of it expressed by several professional men. I am asked, however, if I can point out any modern Gothic building possessing as much originality as the two examples quoted for my edification by S. L., I therefore say that the design for the New Houses of Parliament, displays quite as much originality, and of a far better kind, and would also refer to Cossey Hall, and Harlaxton as being highly satisfactory specimens of modern buildings, in which the Gothic has been treated with originality *con amore*. The hardest charge of all against me remains to be answered: I am quite regardless, it seems, of decency in the choice of my expressions—I believe I was once so indecorous as to write at full length, the naughty word "breeches-pocket," and I may possibly on some other occasions, have expressed myself rather more energy than decorum; but I am not conscious of having ever made use of any expressions of which a gentleman would be ashamed, although of many that would shock those demure, hypocritical persons who are choice indeed as to their words, and seldom further than mere words. However, if S. L. can show up my indecencies and indecorums, he is perfectly at liberty to do so; and then I shall understand better than I now do, in what they consist. For my own part I have no great fancy for the milk-and-water style of writing, nor do I think it at all calculated to operate efficaciously. Did I consider architects to be infants, I should prepare and administer my doses accordingly; whereas there are many it would require a Sixty-Candidus power in order to make any impression upon them. Dainty drawing-room phrases are therefore quite out of the question: to use them—pshaw! it would be like trying to tickle a rhinoceros with a rose-leaf.

Candidus.

DESIGNS WANTED.

Sir—In the *Times* newspaper of to-day (June 4th) is an advertisement inviting architects to send in designs for a Corn-Exchange to be erected at Sudbury, in Suffolk, the drawings for which are to be sent in on the 10th; so that barely three days altogether are allowed for making them, and not even that, unless a person chooses to go entirely by guess, without writing to the secretary (at Sudbury) for further particulars, or rather, for particulars, no other information being supplied by the advertisement than that there will be an area of 78 by 50 feet, yet whether that is the extent of the whole site, or merely of the part of the building appropriated to the Exchange itself, does not very clearly appear.

Surely the people who insert such advertisements must suppose that architects keep a stock of ready-made designs by them, suited for every occasion; or perhaps they may imagine that architectural designs can now be manufactured by steam, and perhaps we shall next be told that the required drawings are expected to be sent down by return of coach or train.

Undoubtedly, if an architect be pricked on with a golden spur, he will be stimulated to extra exertion. But on this occasion, the golden spur has been hammered so very thin, that it is as light as a feather. Hardly, perhaps, will you believe me when I say, that the two premiums amount together to the *extraordinary* sum, as it may very properly be called, of Eight Guineas! viz. Five for the first, and Three for the second! The man who would nibble at such a bait, would nibble the cheese put as a bait upon a mouse-trap. Leaving the preposterous shortness of time allowed out of the question, no professional man, I conceive, would pay attention to such an invitation, stamped as it is with excessive paltriness on the very face of it. Therefore, if responded to at all, it is likely to be so only by junior clerks and office assistants. It might be imagined that so gross a practical blunder as that of affording no time whatever for at all considering the subject—hardly sufficient, indeed, for putting down the first rough ideas upon paper—would not be committed by even the most ignorant. Nevertheless, such we find to be frequently the case, and what is more, that the profession itself makes no effort to put an end to it. One way would be to show up and make an example of every case of the kind. And I would further suggest, that the Institute ought to keep an exact register of all competitions advertised in the public papers, and of their respective particulars and conditions. But, unfortunately, the Institute does not seem disposed to bestir itself in earnest or to the purpose on any one occasion. It seems to be not only without the power, but without the slightest inclination, to effect any good, either for the art itself, or for those who follow it.

I remain, &c.,
Anti-Humbug.

New Steamer at Brighton.—We learn from Brighton that a new steamer built at North Shields for a company at Brighton, and fitted with Mr. Smith's patent screw propeller, on the plan of the Archimedes, arrived at the Chain Pier, on Tuesday morning, from the river Tyne, after the remarkable quick passage of 48½ hours. This vessel is intended to ply from Brighton to the adjacent ports, and to be occasionally used as a tug in towing vessels in and out of Shoreham Harbour. She is about 110 tons, with engines of 45-horse power.

Steam Communication between Dresden and Prague.—The first steam boat that ever made the passage between Dresden and Prague arrived from the latter city on the 30th ult. She is called the Bohemia, and was built expressly for that service, being flat-bottomed, having 121 feet in length, 18 ft. 6 in. in breadth. Her engine is of 40-horse power, and she is of carrying 40 passengers, and a considerable quantity of merchandise. laden with a full freight she draws only 16½ inches of in about 16 hours. She is to travel

NEW INVENTIONS AND IMPROVEMENTS.

STEAM ENGINE FURNACES.

EXPERIMENTS ON THE ECONOMICAL EFFECTS OF FURNACES OF DIFFERENT CONSTRUCTION, AND ON DIFFERENT KINDS OF FUEL.

These experiments have been made by a committee appointed by the Society of Industry of the Grand Duchy of Hesse, and their object has been,

1st. To ascertain the useful and economical results of furnaces for boilers constructed on different principles.

2nd. To establish the relative value of the combustibles most generally used in the country.

We do not consider it necessary to enter into the details of the experiment; we will only mention the results.

In order to decide the first question, a common boiler was set over a furnace of brickwork provided with a chimney, and this apparatus for heating was submitted to various modifications, as regarded the form and structure of the hearth as well as the disposition of the flues.

In order to resolve the second question, experimental trial was made of good dry wood chopped from the beech tree; of good coal from Roer, called *Fettschrot;* and of square pieces of turf from Greisheimer, perfectly dried, and of the heaviest kind.

The different modifications used in the construction of the furnace were the following:

I. Furnaces without flues or draught chimneys, the boiler being suspended freely above the fire.

II. A simple flue passing round the boiler, the bottom part of which only was immediately exposed to contact with the fire burning in the grate.

III. A double flue, that is, a flue going twice round the boiler in the same direction.

IV. A stove arched in the shape of a cupola, and having an opening in the middle of the arch, which became gradually wider towards the top, and by which the heat ascended, and was communicated to the bottom of the boiler, to be afterwards conveyed by three holes, placed at regular distances, into a circular passage which surrounded the boiler; to issue thence through three similar apertures differently arranged, and which communicated with a second passage placed higher, whence the draught was at length conducted into the chimney.

V. Two half flues, that is, each of which did not extend beyond half the circumference of the division of the boiler. The fore part of the flame (on the side next the door) ascended from the stove, and was distributed half into the flue on the right, half into the flue on the left, and was finally conducted into the chimney at the point where they met.

VI. Four half flues, or two on each side the boiler (from right to left); the flame issuing from the side opposite the door entered into the lower flue, then passed half the circumference of the partition of the boiler, and entered into the upper flue, whence it was finally conducted into the chimney.

The relative effects of these different arrangements have been ascertained, both with respect to the quantity of water evaporated in the boiler, as well as that of the combustible employed; particular care being taken to keep up the same level in the boiler after each experiment.

In the following table, which contains results of the experiments, the numerals indicate the different methods of construction of the furnaces in the order in which they have been described above; the figures placed underneath indicate the relative qualities of the combustibles employed to obtain a similar result; consequently the greater amounts indicate the worst methods of employing combustibles:—

Wood	VI	V	III	II	IV	I
	63	68·8	69·69	72·19	72·23	100
Turf	VI	III	IV	V	II	I
	53	66	71	72	76	100
Coal	III	IV	II	V	IV	I
	73	76	83	85	91	100

The following are the conclusions to be deduced from the foregoing table:

1. The fire over which the boiler was placed without flues was attended with a less advantageous use of combustible than those with flues.

2. The utility of flues is much more perceptible in fires of wood or turf than in coal fires, because the result is a saving in fuel of about one-fourth to one-third with wood, and almost of one-fourth to one-half with turf, and only of one-tenth to one-fourth with coal, by the addition of flues.

3. The mode of construction with four half flues (No. VI.) may be considered to be generally the most advantageous. Next to this the construction with a double flue (No. III), which in its mode of action bears the nearest resemblance to it. With respect to the arrangements Nos. II., IV., V., the effects they produce are nearly similar.

4. The double flue (No. III), which surrounds the whole boiler, is attended with better results than the single flue (No. II); according to the same principle, four half flues (No. VI) are attended with better results than two half flues (No. V).

5. With the fire of wood and of turf, two half flues (No. V) have more effect than a whole flue (No. II), and four half flues (No. VI) more than two whole flues (No. III); in short, flues which encircle only half the boiler are in this case more effectual; while with a coal fire it is precisely the contrary. The cause of the difference is doubtless this, that in such combustibles as wood or turf, which blaze brightly, a retardation of the heated air, which in these half flues produces a sudden change in the direction of its motion, is more advantageous than with coal.

With respect to the calorific power of the different fuels, there results from equal weights of turf, 96, and of coal, 250, when that of wood is considered equal to 100.

The great difference that is found in combustibles, with respect to their natural quality and their composition, as well as in their degrees of dryness, can scarcely admit of forming points of comparison between these latter results and any other given case. It is well known that there are turfs which from an equal weight throw out more heat than wood; but the results with respect to the different methods of constructing furnaces are more to be depended on; because in these are remarked a degree of regularity in their effects, and it is easy to account for the causes on which the differences depend.—*Moniteur Industriel.—Inventor's Advocate.*

LOCOMOTIVE EXCAVATOR.

This French machine is stated to be the invention of M. Gervais, of Caen. The trial of the apparatus was made in the presence of a committee of the Society of Emulation at Rouen, and of many of the distinguished residents of the town, and the result is said to have left no doubt of the possibility of making excavations by the power of steam. It is said to be particularly applicable in digging canals, and making the excavations for railways. The apparatus is placed on a large heavy kind of carriage, in the fore part of which there is a steam-engine of six horse power, with oscillating cylinders and a tubular boiler, which works the machine, and also turns the two fore wheels very slowly, so that the whole is gradually moved forward as the work progresses, large pieces of wood being laid down to form temporary rails over which the machine is propelled. Towards the back of the machine there are two machines similar to dragging machines, which raise the earth that has been dug out, and deposit it in a horizontal endless chain of buckets, which carry the excavated earth beyond the limits of the trench, and there deposit it, forming an even and regular bank on each side. The excavating apparatus is placed about the middle of the carriage. It consists of four iron shafts parallel to each other and equi-distant, the whole four having their axes in the same plane, and forming an angle of fifty degrees to the horizon, the incline being towards the back of the machine. Each shaft has attached to it five double arms, equi-distant from the bottom to the top, and each arm is furnished with a spade-shaped tool. These shafts, therefore, present forty spades working at different heights, which dig a ditch nearly three metres in width and upwards of one metre in depth. Each of these excavating tools when in action strikes against the earth ten times in a minute. These revolving excavating shafts are put in motion by the steam-engine, and the action of the engine is so regulated that the whole machine progresses at the rate of about twelve metres an hour. The whole of the machinery, including the carriage, weighs about 24,000 kilogrammes, or 15 tons. When, owing to the nature of the soil or the presence of large stones, the action of the tools is resisted, the locomotion is stopped, and the whole apparatus is made to back, so as to enable men to remove the obstruction. The trenches dug by this machine are very exact, the sides are perpendicular and smooth, and the earth thrown out forms on each side a regular embankment. A machine of this kind was some time since shown by M. Gervais to the French Academy of Sciences, on which they reported very favourably, but it was not provided with the means of locomotion, nor was it on so large a scale as the machine at Rouen. *Ibid.*

CALOTYPE.

It has been known for some time, that Mr. Fox Talbot, in the progress of his experiments to render more perfect the art of photogenic drawing, had discovered a means by which paper could be made far more sensitive to light than heretofore. The impressions, however, so quickly obtained by this new method, are in the first instance *invisible*, but by a process similar to the first, they are made to appear with even greater power than in ordinary photogenic drawing. On Thursday evening, June 10, Mr. Talbot read a paper at the Royal Society, in which he described the new process, called, for distinction's sake, *Calotype*; and as the subject is one of general interest, we shall here briefly describe it:—The paper is covered with iodide of silver, by washing it successively with nitrate of silver and iodide of potassium. Afterwards it is washed over with gallo-nitrate of silver, the greater part of which is removed by immersion in water, but enough adheres to render the paper exceedingly sensitive to light. The paper is then dried, and placed in the camera obscura, and the image of a building, or other object, is generally obtained in less than a minute. This image, however, is usually quite invisible; and the mode of rendering it visible (which is the most curious part of the Calotype process,) consists in washing it again with gallo-nitrate of silver and then gently warming it, which generally causes the appearance of the picture with great force and vivacity in the space of a minute or less. The gallo-nitrate of silver is formed simply by mixing solutions of nitrate of silver and gallic acid. The operation requires to be executed with great care and precision, but is not difficult in other respects. The theory of the process remains, at present, unexplained.—*Athenæum.*

IMPROVEMENTS IN FURNACES AND BOILERS.

Charles Wye Williams, of Liverpool, gentleman, for certain improvements in the construction of furnaces and boilers. Enrolled at the Petty Bag Office, May 17. Claim first.—The use and application of metallic pins as conductors for transmitting heat. This part of the invention consists in inserting metal pins in the plates of which boilers, evaporating pans, &c., and pipes, &c., attached to the same, are composed; part of each pin extending through the bottom of the vessel into the liquid to be heated or evaporated, and the other part projecting outside of the vessel into the fire beneath it, by which arrangement a greater quantity of heat is transmitted to the liquid than [illegible] would be by the usual method.

Claim second.—The mode of giving the longitudinal and vertical movements to the fire-bars of a furnace; also the extension of the fire-bars outside of the furnace, so as to receive fuel from a hopper, and spread it evenly over the fire-grate.

The fire-bars are serrated (the elevated parts being wedge-shaped, and the depressions quite smooth), and incline downwards from the fire-door towards the bridge of the furnace, their lower ends resting on a bar, on which they are capable of moving vertically up and down as on a centre; the other ends terminate beneath a hopper outside of the fire-place, but within the fire-door; they are supported at this end by eccentrics placed on a horizontal shaft, which, being turned by hand, or by gearing from the steam-engine, communicates the up-and-down movements to the fire-bars, and the fuel being received from the hopper on to the outer ends of the fire-bars, is urged with a gradually diminishing force towards their inner ends, and spread evenly over the surface of the fire-grate. By the continued movements of the fire-bars the generation of clinkers is prevented.—*Inventors' Advocate.*

IMPROVED APPARATUS FOR CUTTING AND SHAPING METALS.

Joseph Whitworth, of Manchester, engineer, and John Spear, of the same place, gentleman, for certain improvements in machinery, tools, or apparatus for cutting and shaping metals, and other substances. Enrolled at the Petty Bag Office, May 17.

The first part of this invention consists of an improved die for cutting screws. The principle upon which this die is formed may be described as effecting the following object, viz. to cut a screw-thread at any required depth with dies, which have themselves been cut by a master-tap, double the depth of the thread, larger in diameter than the shaft on which the thread is to be cut. The improved die is formed from the common die, by dividing the same either into two equal parts (the plane of section being parallel to the sides of the die), or into three unequal parts, in which latter case the two planes of section are parallel with each other, but at an inclination to the sides of the die. In working this die, its plane of direction, instead of passing from the axis of the shaft on which the thread is to be cut to the centre line of the die, as in ordinary dies, passes outside of the said line. The patentee shows an improved stock, of a very simple construction, to be used with the die.

The second part of this invention is an improved mode of actuating the planing machine, described in the specification of a patent obtained by Mr. Joseph Whitworth, in 1839.

The third part of this invention consists of improvements in slotting machines, the chief feature of which is the compound moving table. This table consists of three parts, the lower part sliding along the bed of the machine; the middle part moving at right angles to the lower one; and the top one having a rotary movement communicated to it.

The fourth part is an improvement in the slotting bar. An angular groove is cut down the back of the bar to receive a strip of metal tapped for small set screws, by which the positions of the cutters are adjusted, and in the front of the bar recesses are scooped out round the cutters, to afford room for the cuttings.

The fifth part is an improvement in the slide lathe, and consists in attaching an apparatus to the headstock or mandril frame of the lathe, for the purpose of forming, together with the change-wheels, a more perfect communication between the mandril and guide-screw.

The last part consists of an apparatus for "truing up" the wheels of carriages and engines on railways. The apparatus is applied to a pair of wheels in the following manner:—one end of a connecting rod is attached by a stud to the outside bearing of each wheel below the axle, and the other ends of these rods are fastened to a horizontal bar parallel to the axle; on this bar a sliding bar composed of two parts moves, each of its outer ends being provided with a grinder or cutter, placed opposite to and in contact with the outer rim or tire of each wheel; the inner ends of this sliding bar are joined together by an eccentric pin passing through them, fastened on a horizontal wheel, which has its bearings on the under part of the horizontal bar; this wheel is turned by an endless band, from a small pulley on the axle of the running wheels. Motion being communicated to the horizontal wheel, it will, by means of the eccentric pin, cause the two parts of the sliding bar to move alternately a short space backwards and forwards, by which means the grinders on their outer ends will be caused to traverse from side to side of the tire of the wheels as they revolve, and thereby grind down any inequalities of the same.—*Ibid.*

UNIVERSAL CHUCK FOR TURNING AND BORING.

Alexander Stivens, of Manchester, engineer, for certain improvements in machinery or apparatus to be used as a universal chuck for turning and boring purposes. Enrolled at the Petty Bag Office, May 19. The patentee claims the peculiar and novel arrangement of apparatus constituting a universal chuck, without confining himself to the number, size, or dimensions of the levers working on the central boss.

The chuck is formed of two plates, viz., a front plate and a back plate, in the former of which are formed three radial mortices; the three holding nogs or dies are attached by screws to dove-tail slide-pieces, which slide backwards and forwards in the mortices. In one of these pieces a nut is formed, in which a screw works, its outer end being supported in a bearing on the edge of the front plate, so that on turning the screw round by means of a key applied to its outer end, the slide-piece will be made to traverse to and fro in its mortice. To each slide-piece is attached one end of a straight lever, the other ends of which levers are attached to an equilateral triangular lever, working loosely on the centre boss of the chuck; by this means, on the screw being turned, the slide-pieces will advance or recede simultaneously within their mortices.—*Ibid.*

IMPROVEMENTS IN DETACHING LOCOMOTIVE AND OTHER CARRIAGES.

Francis Pope, of Wolverhampton, Engineer, for improvements in detaching locomotive and other carriages. Enrollment Office, May 24. This invention consists of an ingenious piece of mechanism by which a horse can be instantly detached from the vehicle to which he is attached, or one carriage can be separated from another on railways. When applied to horse carriages, each shaft terminates in two iron side plates carrying a pin which form the axis of the shafts, and is the means by which they are attached to the carriage. There are also two side plates attached to the carriage, carrying a pin which forms the axis of motion to a bent lever or tongue; this tongue when turned back embraces the pin on the end of the shafts, and holds it securely in the recess formed for it. The tongue is held down by a peculiarly formed spring catch, to which a lever is affixed. So long as the tongue is held down by this catch, the shafts are securely held to the carriage, but on pulling the lever the catch is disengaged, the tongue flies over and the shafts and horse are released. When applied to railway carriages three of these attachments are employed, the centre one being a bar corresponding to the end of the shafts in the former case, and the two outer ones being chains. The three catches are simultaneously acted upon by an apparatus terminating in a handle which runs up to the seat of the guard. The claim is to the mode of constructing and applying apparatus as described.—*Mechanics' Magazine.*

CASE-HARDENING IRON.

Robert Roberts, of Bradford, Lancashire, Blacksmith, for a new method or process of case-hardening iron. Enrolled at the Petty Bag Office, May 25. This method consists in heating the iron and plunging it into cast iron in a state of fusion and turning it about, when it will become cased to any required thickness from $\frac{1}{16}$ to $\frac{1}{4}$ an inch, when it is to be plunged into cold water, and will then be found to be effectually case hardened. The claim is to the method or process of case-hardening iron, by coating, covering, or combining wrought iron with cast iron.—*Ibid.*

IMPROVEMENT IN PADDLE-WHEELS.

Henry Charles Daubeny, Esq., Boulogne-sur-mer, France, for a certain invention or improvement in the making and forming of paddle-wheels, for the use of vessels propelled in the water by steam or other power, and applicable to propel vessels and mills. Enrollment Office, May 25. The floats are mounted on spindles or axes, one end of which work in a box or centre, the others in the circumference of the paddle-wheel. Near the ends of the spindles which works in the box, there are short levers which work against a traverse, so as to expose their broad surface to the water, while they enter and quit it edgeways. By this feathering operation, all the inconveniences arising from back water are obviated. In order to relieve the paddles from the effects of heavy [illegible], they are provided with an escapement consisting of two or more cogs let into the box of the wheel, and traversing round with it in a groove provided for that purpose in the flanch or carrier, fixed on the end of the main-shaft; in this groove there are bridges which cause the cogs in passing them to throw up their front ends, and thus present their hind ends opposite to abutments formed in the face of the carrier, which, coming in contact with the hinder ends of the cogs, turn the paddle-wheel round. In the event of this wheel being struck by a heavy sea, the blow causes it to revolve faster than the carrier, and thereby relieves it from the injurious effects of the concussion. When the force of the sea is expended, the abutments again come in contact with the cogs, and the wheel is driven round by the effects of the engine. A mode of placing paddle-wheels in an inclined position is shown, by which means external projecting paddle-boxes are dispensed with.—*Ibid.*

IMPROVEMENTS IN STOPCOCKS.

Henry Bridge Cowell, of Lower-street, St. Mary's, Islington, Middlesex, ironmonger, for improvements in taps, to be used for or in the manner of stopcocks, for the purpose of drawing off and stopping the flow of fluids. Enrolled June 2, at the Roll's Chapel Office.

The first part of this invention consists in applying a moveable stopper to the spout of a tap, such stopper being suspended at the lower ends of two upright connecting links, one at each side of the spout, which link pass down through holes or sockets in the metal of the head of the tap. The upper ends of these links are connected to a piece of metal or collar, situated above the head, and fitted around a screw that turns in the same, so that on the screw being turned it will either rise or fall, and consequently raise or lower the stopper, thereby opening or shutting the spout of the tap. The fluid which escapes round the sides of the orifice of the spout on the stopper being lowered will be collected in the hollow mouth of the tap, so as to run out in a compact stream from the lower orifice.

The second part of this invention consists in applying to a ball-cock (similar in its parts to the tap just described) a second ball and lever, provided with a click or detent, having a tooth, which catches into a notch or notches cut in the circumference of an enlarged head on the end of the screw before mentioned. The click is mounted on a centre pin fixed in the collar of the screw, so that whenever the other ball descends the tooth catches into one of the notches, and turns back the screw, thereby opening the passage through the cock for the water. The usual ball is kept submerged during the flowing in of the water into the cistern, by means of the click preventing the screw to which it is attached from being turned; but when the surface of the water reaches the second ball, and raises the same upwards, the click will be lifted up about its centre of motion, so as to disengage its tooth from the notch in the head of the screw, whereupon the other ball will immediately rise to the top of the water by its power of floatation, and close the passage of the cock.

The third part of this invention consists of another kind of tap, similar in some respects to the one first described.—The moveable stopper is fitted in the manner of a piston into the cylindrical hollow of the head of the tap, so as to move up and down therein by the action of a screw working in a cap that surmounts the head of the tap; by turning this screw round, the stopper is pressed down on the upper orifice of the water-passage of the spout, and at the same time over the annular orifice of a circular channel formed within the head of the tap, and passing round the water-passage, through which channel the water is conveyed to the passage. Thus on depressing the stopper the flow of water will be stopped, but on raising the same the water will be permitted to flow again.—*Inventors' Advocate.*

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

INSTITUTION OF CIVIL ENGINEERS.

February 23.—William Cubitt, V.P. in the Chair.

The following were balloted for and elected: Colonel Sir Frederick Smith, R.E., William Chadwick, John Bazley White, jun., Charles Lorimer Hensman, Joseph Whitworth, and Evan Hopkins, as Associates.

"*Description of a new mode of Steering, as applied to boats of light draught of water, navigating shallow and rapid rivers.*" By Captain Henderson, Assoc. Inst. C.E.

The ordinary method of steering with a single rudder, fixed in the usual manner, will bring a vessel round in about four times its length, upon an axis at the point of union between the dead wood of the vessel and the rudder. It was found desirable for the particular service on the Ganges and Burhampooter, for which the vessel in question was designed by the Assam Company, that great facility should be given for coming round rapidly; to accomplish this, the stem and stern of the vessel are alike provided with rudders, of a form adapted to the curvature of the craft. The stern rudder is considerably larger than the other, and occupies the space usually allotted to the dead wood, which is cut away; a more immediate influence is thus exerted upon the boat. The rudders are raised or lowered according to the draught of water, by means of capstans fixed upon the projecting ends of the shaft of a pinion, which is geared into a toothed racked of peculiar construction, on the back of each rudder post. The effect of this arrangement is, that the centre of revolution is transferred to a point nearer the centre of the vessel, and deviating from the true centre, in proportion to the relative dimensions, position and figure of the two rudders, and of the lines forward and abaft the vessel, which is thus brought round in little more than its own length.

The vessel, of which a model accompanied the paper, is fitted with condensing engines working expansively, with a pressure of steam of 20 lb. in the boiler; the cylinders are placed at an angle towards the paddle shafts, and act directly upon the cranks without the intervention of side levers.

"*Description of a Coffre Dam used in excavating Rock from the navigable Channel of the river Ribble.*" By David Stevenson.

The navigation of the river Ribble being much impeded by natural bars or weirs of sandstone rock, compact gravel, or loose sand, several ineffectual attempts were made to remove these hindrances, and eventually a joint stock company, called the Ribble Navigation Company, was formed for that purpose. Messrs. Robert Stevenson and Sons (of Edinburgh) were consulted, and under their directions the present works were commenced: their plan was to cut a channel in the rock wherever it was necessary, and to remove the gravel and sand by steam dredging, forming at the same time a low rubble wall upwards of a mile in length, for the purpose of directing the course of the river so as to obtain a permanent and straight navigable track for the shipping. The first of these operations is alone treated of in the communication.

About half a mile below Preston, a bed of sandstone rock, upwards of 300 yards in length, stretches quite across the river; some portions are entirely free from any deposit of sand or mud, and the higher parts are frequently left dry during the summer months. This natural weir exerts such an influence upon the flow of the tides, that neap tides which at 12 miles distance rise 14 feet, are not at all perceived at the quay at Preston.

It was proposed to cut a channel through this bar, 100 feet in breadth, affording an average navigable depth of 20 feet at high water of spring tides. In some places, therefore, the excavation would be 13 ft. 6 in. deep. After much consideration it was determined to make use of a series of coffre dams, as the most effectual and economical mode of proceeding. Their construction may be thus briefly described:—

A double row of wrought-iron bars, 2½ inches diameter, with *jumper* points worked upon them, were inserted vertically into the rock at regular intervals of 3 feet apart laterally, the second row being placed 3 feet behind the front row. When a sufficient number of bars were fixed, a tier of planking, 3 inches thick, with clasps to enable the planks to be fixed to the rods, was placed withinside. The lower edges of the planks were cut out roughly to the inequalities of the rock; they were then lowered, and by means of an iron rod, with a crooked end, those parts which did not touch the bottom were ascertained, and a change in the form made, until the plank rested its whole length on the rock: the lower edge was then bevelled off, and being finally lowered to its place, the plank was beaten down by the force of a heavy mallet, upon an upright piece of wood resting upon the upper edge of the planks; the lower bevelled edge yielding to the blows, sunk into the irregularities of the rock, and thus ultimately, in connexion with the puddle behind it, formed a perfectly water-tight joint. The lower planks being fixed, the upper ones were placed upon them; transverse tie bars were inserted at intervals; and the clay puddle was formed in the usual manner. In order that the navigation of the river should not be impeded, the diagonal stays were all placed inside the dams. These stays had joints at the upper ends, and being slipped over the tops of the iron rods, and kept in their places by cotters, their lower ends could be moved either horizontally or vertically, as the irregularity of the rock required:—as the excavation proceeded, longer stays were easily substituted, by merely removing the cotter, sliding up the short stay, and replacing it by another suited to the increased depth. The sides of the dam were kept together by bars of iron connected to two horizontal wale pieces, 10 inches by 6 inches, placed on the outside of the vertical iron rods. When the dam was thus constructed, the water was pumped out by a steam engine of 10 horses power, with two pumps of 12 inches diameter.

The whole of the excavation, which was 300 yards in length, and 100 feet in width, was to be completed with three lengths of coffre dams, so contrived as to include within the second stretch the lower side of the first dam, in order to excavate the rock in which that row of piles was fixed. The first and second lengths have been most successfully executed; the third is now in progress, and the excavation is proceeding very rapidly. The sandstone rock does not require gunpowder. The total quantity to be excavated is estimated at 31,000 cubic yards; all the stone which is raised is used in the construction of the wall for directing the course of the lower part of the river.

Some doubt existed in the mind of the engineer as to the security of the fastening of the iron rod piles by merely jumping them from 15 to 18 inches into the rock; they have, however, proved to be perfectly firm during heavy floods, when the whole dam has been submerged, and the velocity of the current which was rushing over it was not less than five miles per hour.

This paper was accompanied by two drawings, showing the general arrangement of the work, as well as the details of the construction of the coffre dam.

March 2.—The President in the Chair.

The following were balloted for and elected: Peter Hogg, Henry Oliver Robinson, Thomas Oldham, Edward Jones Biven, and Robert Ransome, as Associates.

"*On a new form of Railway Chairs and improved Fastenings.*" By Charles May, Assoc. Inst. C.E.

At the suggestion of Mr. Cubitt, V.P., a series of experiments was instituted at the works of Messrs. J. R. & A. Ransome, of Ipswich, for the purpose of determining the most advantageous form of the chairs, and most secure mode of fastening them upon the sleepers of the South Eastern Railway. The result of these experiments has been to produce the cast iron chairs, and wooden treenails as fastenings, which were exhibited at the meeting, and described by the author.

In the event of a chair breaking, it is desirable that the fracture should occur in such a manner as to prevent any of the loose pieces being thrown into situations where they would interfere with the passing trains; to ensure this, the weakest part of these chairs is across the seat—they are, however, stronger in that part than any other chair now in use. In order to ascertain the proper relative proportion between the strength of the jaw and that of the seat, many experiments were made by varying the forms, and wedging the chairs, until they broke, sometimes in one and at other times in the other part; it was then easy to add so much strength to the jaw as would, without waste of metal, cause the fracture to take place invariably across the seat.

For the purpose of ensuring perfect accuracy of form, with a smooth internal surface, so that wedges of a uniform shape and size might be used, the chairs are cast upon metal cores; the joint-chair has an upper piece, overlapping the wedge, to keep the rail in a perpendicular position, and to prevent the end of it from being thrown up or forced away laterally, if the wedge should accidentally be removed. This form of chair was originally planned by Mr. John Harris, the engineer of the Stockton and Darlington railway, where it has been in use above twelve months, giving perfect satisfaction. The rail is so placed in the intermediate chairs, that when it receives the pressure of the wedge, it is held firmly down on the seat, against the lower part of the jaw, and at the upper part against a slightly projecting rib, which bears against the neck of the rail.

The holes for the fastenings are so arranged as not to be in the same line; a large portion of the current expense of the maintenance of way on railroads arising from replacing the sleepers which have been split by the spikes being driven in the same line in the grain of the wood.

The mode of fastening adopted in this case is, to use treenails of dry English oak, compressed into two-thirds of their original bulk, by being forced under a fly press, into metal tubes, in which they are placed in a chamber heated to about 180°, where they remain 16 hours: the pressure upon the body of the treenail (the head not being compressed) is sufficient to materially increase the specific gravity without injuring the fibre, or diminishing the strength of the wood, and it retains the form thus given until it has been driven into a damp sleeper, when the expansion is sufficient to fix it firmly.

The ordinary mode of fastening chairs with iron spikes has been found disadvantageous, because one blow too many causes a reaction, and frequently loosens them, whilst treenails may be driven to any depth, and the heads subsequently split with small wedges if necessary.

Rails should be 'keyed-up' so tightly as to ensure security, still leaving a large amount of surplus strength in the chair to resist any shock to which they may be exposed:—with wedges of varying dimensions, the chairs, which are frequently of unequal quality, and carelessly cast, are liable to be brought nearly to the breaking point, and to give way as soon as they are subjected to any additional strain. This has been avoided in the chairs and wedges under consideration, by giving them exact uniformity of dimensions.

The wedges adopted are of English oak, cut out of square timber, so formed as to drive equally well with either side to the rail, and compressed into five-sixths of their bulk, by the same process as is used for the treenails.

Many advantages will result from this form of chair and wedge, with the treenails for fastening; the time occupied in laying the rails is diminished; the holes for the fastenings may be bored in the sleepers by machinery, at a diminished cost, and greater accuracy of gauge obtained at the same time; the required inclination of the rail being given in the chair, no cutting away of the sleeper is necessary; the sole of the chair is fixed horizontally upon the surface of the sleeper, and all of them may be placed accurately in the same plane, thus bringing to bear upon the hitherto roughly executed details of railway engineering, those mechanical contrivances by which the cost is diminished, whilst the dependance upon the skill and attention of the workmen is avoided; at the same time insuring the accuracy of the line, upon which so large a portion of the economy of working a railway depends.

Specimens of the chairs, wedges, and treenails, accompanied this communication.

Mr. Cubitt observed, that two modes of preparing treenails had been hitherto adopted: one was, by forcing the wood through a steel die, in which case neither the form nor the diminished bulk was preserved, as on leaving the die it swelled nearly to its original size. The other was by passing the wood between rollers: this latter process had been found to cause permanent injury to the fibre of the wood, by crushing the capillary tubes, and consequently depriving it of much of its strength. To the mode of preparing the treenails under consideration, neither of these objections existed. He anticipated many advantages from the use of this form of chair, wedge, and fastening. They would certainly be cheaper even in the first cost than the ordinary chairs, fastened down by iron spikes. The usual calculation for a double line of rail was 880*l.* per mile for the chairs, wedges, and spikes. The cost of these chairs, with the compressed wedges and treenails, would be 786*l.* per mile. The price of the compressed treenails for railway purposes would be 5*l.* 10*s.* per thousand; that of iron spikes was 6*l.* 5*s.* per thousand. The wedges 2¼ inches square, cost 2*l.* per thousand for each inch of their length, so that those for the joint-chairs, which are 8 inches long, average 16*l.*, and those for the intermediate chairs, of 6 inches long, cost about 12*l.* per thousand. Each joint-chair, with wedge and treenails, costs 2*s.* 10*d.*; and the intermediate ones, with their appendages, 2*s.* 1*d.* each.

One great cause of expense on railways was the fracture of the chairs during the laying. He knew an instance where in a length of 20 miles of railway 180 tons of chairs had been broken, either by wedging or in driving down the spikes. This was in the ratio of one chair in ten. In the ordinary mode the oak wedges are driven home by a 14 lb. sledge hammer, whereas with the new chair the compressed wedges and trenails are driven by a light wooden mallet.

Mr. Pim remarked that the wood fastenings used for the chairs on the Dublin and Kingston Railway had been compressed by rolling. He considered the present plan much superior.

Mr. Vignoles corroborated the statement of the [illegible]t of chairs of the ordinary construction. On the railways of the north of England oak treenails had been used as fastenings for a considerable period. The plan now proposed presented many advantages, not only in the construction of the chairs, which appeared well designed and excellently cast, but in the form and mode of preparation of both the wedges and the treenails.

In answer to a question from the President, whether the compressed treenails could be applied with advantage in ship building—Mr. Mills was of opinion they could be so employed, provided the fibre was not injured by the process. He believed that sound wooden treenails were better fastenings for ships than iron bolts, and quite as good as copper, whilst by their use the expense was materially reduced. Turned treenails of locust wood were at present preferred to all other kinds.

Mr. S. Seaward understood that, at the Royal Dockyards, treenails which were crooked as much as three times their own diameter were preferred to straight ones. He believed that the late Mr. H. Maudslay had constructed some machinery expressly for turning them crooked.

Mr. Hawkins remarked that the treenails were frequently crooked, because the rending caused them to follow the direction of the grain of the timber. Twenty-two years since, Mr. Annesley took out a patent for building ships without ribs. He used for fastenings, treenails compressed by being forced through steel dies, just before driving them into the planks, so that their expansion fixed them firmly in the planking. He built a vessel of very light construction, the sides of which were formed of five thicknesses of ½-inch boards, held together by compressed treenails, without any ribs. It had proved very stiff and durable.

In reply to a question from Mr. Vignoles, whether the swelling of the compressed treenails in the ribs would not have the effect of preventing the possibility of the "butt end" of a plank starting—Mr. Mills believed that such an event was of rare occurrence; treenails were subjected more to a lateral strain; they were frequently "backed out" after the planks had been fitted into their places; when the latter were properly bent they retained their shape, and had no tendency to spring out.

Mr. S. Seaward, in support of the opinion that leaks did occur from planks starting, instanced the "Marquis of Huntly," East Indiaman, which was injured in the Downs, by a collision with another vessel; she proceeded on her way to China, but during the whole voyage out and home forty extra men were employed at the pumps. On being taken into dock, it was found that the "butt end" of one of the bow planks had started for 8 or 9 feet in length, and nothing but constant labour and attention had kept the ship afloat, at an expense of 7,000*l.* to the owners.

March 9.—The President in the Chair.

The following were balloted for and duly elected: Joel Spiller, as a Member; John Pope, as a Graduate; Thomas Routledge and Frederick Taylor, as Associates.

"*Description of a Bridge for a Railway crossing above a Turnpike Road, where the depth between the soffit of the Bridge and the surface of the Rails is limited, to twenty-one inches.*" By John Pope, Grad. Inst. C.E.

This bridge was designed by Mr. W. Cubitt, V.P., to meet the conditions of a clause in a Railway Bill, which required that there should be a clear width of opening for headway through the bridge in every part, 30 feet wide by 20 feet high, whilst at the same time the height of the embankment limited the space between the under side of the bridge and the surface of the rails to 21 inches.

The railway is carried on three cast iron girders, each 3 feet deep at the centre, diminishing to 6 inches at each end, with a bearing of 2 feet on cast iron wall-plates, supported by brickwork abutments. The flanches of the girders are 8 inches wide, and the metal every where 2 inches thick. Balks of Memel timber, 12 inches square, are laid transversely, close jointed, their ends bearing upon the flanches of the girders: on these timbers the chairs are fixed, and the rails are laid. The whole depth employed is—

The flanch of the girder	- -	2 inches
Thickness of timber balks	- -	12 "
Depth of the rail and chair	- -	6¼ "
		20¼

One of the girders on each side supports the parapet wall in which it is completely encased, and being faced with cut stone, assumes the appearance of a flat camber arch, 3 feet in depth.

A detailed drawing, showing minutely the construction, accompanied this communication.

ARCHITECTURAL SOCIETY.

Conversazioné held Tuesday evening, the 1st of June, 1841, William Tite, Esq., President in the Chair.

After the report of the proceedings of the Society during the session was read, the President delivered a very interesting lecture, "*On the researches made in Egypt, at the expense and under the authority of the Tuscan Government.*" By Signor Rosellini. The lecture was illustrated by a variety of drawings, models, and valuable engravings, which very considerably enhanced its interest.

At the completion of the lecture the President announced the agreeable duty which he had to perform, in the distribution of the prizes which had been awarded by the Society for competition during the past session; at the same time he expressed his regret that the students had not been more active in the other classes of competition, and stated that although prizes had been offered by the Society for competition in the class of original design, in the class of measured drawings from a public building, and also for the best fairly transcribed notes of the Professor's lectures, yet it became his painful duty to state that no competition whatever had been attempted in either of these classes; neither was there any competition for the prize offered for the best drawing of the human figure from a plaster cast in the possession of the Society. Having made these observations, the President proceeded to the distribution of the two prizes which had been awarded, viz., to Mr. Arthur Johnson, for the greatest number of the most approved sketches from subjects given by the Architectural Society during the session 1840 and 1841; and to Mr. Frederick Johnstone, for having produced the best drawing from a plaster cast in the possession of the Architectural Society, session 1840 and 1841. The President called the attention of the meeting to some specimens of a patent which had been obtained for uniting lead and other metals without solder, which he was of opinion was worth the consideration of persons connected with building. He then announced that the business of the meeting, and of the session was concluded, and in so doing directed the attention of the visitors and other gentlemen present to the various specimens of art contributed for the evening's entertainment; among which was a very beautiful drawing, being a representation of the shield to be presented to Lord Eglinton, in commemoration of the late tournament held under his superintendance, both the design and drawing were by Mr. Henry Nixon. Also a newly invented ball-cock patented by Mr. Henry Abraham, the architect; likewise a cast in bronze of an elaborately chased Roman vase, together with sundry specimens of Roman tesselated pavement.

There was also exhibited a very beautiful model in plaster of Mr. Tite's (the President) portico of the New Royal Exchange, as approved and decided by the Gresham Committee, to be erected—it elicited considerable praise and attraction. There was another model of the New Church now erecting at Muswell Hill, under the direction of William Barnes, Esq. Also sundry models by Mr. Samuel Nixon, as well as numerous drawings by Henry Nixon, Clayton, G. B. Moore, Punnett, Meredith, William Barnes, G. Mair, William Grellier, William Nunn, &c. &c. The meeting was numerously attended, and was favoured by the presence of many of the leading and most scientific men of the day.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

June 7.—A paper was read by the Rev. R. Burgess, Hon. Member, on the Roman temples. Mr. Burgess traced, in a most interesting and entertaining narrative, the history of the temples of antiquity, from the rays encircling the heads of the heathen deities, originally applied as a protection to the heads of their statues, and the niches in which they were subsequently ensconced, down to the gorgeous edifices of the Roman empire.

June 21.—Mr. T. L. Donaldson, Fellow, read a description of the column erected at Petersburg in honour of the late Emperor Alexander. The construction of this monument rivals that of the best ages of antiquity. The shaft is monolithic, of polished granite, 84 feet in length. The pedestal is also a single block of the same material, and so carefully has the durability of the work been considered, that two vast masses were successively rejected after they had been extricated from the quarry as not being sufficiently perfect. Possessed as we are in Great Britain of granite quarries capable of supplying stones of almost unlimited dimensions, it is to be regretted that such an example should be lost upon the directors of our public works. Unfortunately the example is likely to excite nothing but feelings of horror and contempt for so outrageous a dereliction of the principles of economy!

A paper was afterwards read on the open roofs of the middle ages, by T. Morris, Esq.,—many examples were exhibited and described. It appeared to be the general opinion of the meeting, that the scientific skill displayed in these beautiful and picturesque combinations of timber work has been greatly overrated. Some have signally failed, as at Eltham, while in others, as at Westminster Hall, the principle resolves itself, on examination, into the simplest elements of [illegible]. The durability of these structures seems rather due to the mechanical construction of the carpentry, in which they are worthy of the greatest admiration.

MESSRS. COOKE AND WHEATSTONE'S ELECTRIC TELEGRAPH.

(From the Railway Times.)

We have given many occasional notices of this admirable invention—of its adoption on the Great Western and Blackwall Railways, and its surprising performances in both instances—but it still remains to us to lay before our readers such a detailed account of the apparatus as may enable them to comprehend fully the mode of its operation, and to estimate duly its great practical efficiency. We cannot help thinking that it must be owing in a great measure to a prevailing paucity of information on the subject of the invention, that it is not making its way more rapidly into use, and believe we shall render good service to the railway interest by doing our best to make its value more clearly, distinctly and generally known. For the following descriptive details, and the numerous engravings by which they are illustrated, we are indebted partly to the evidence given by Professor Wheatstone before the Select Committee of the House of Commons on Railways, and partly to a set of drawings with explanatory letter-press recently published by the Professor's managing partner in the invention, Mr. Cooke. Some doubts it will be recollected were raised respecting the proportions in which Messrs. Wheatstone and Cooke divided between them the merit of the invention; but these doubts have been for ever removed by the statement on the subject which we published three or four weeks ago, drawn up at the mutual request, and (we believe) to the satisfaction, of these gentlemen, by their friends Sir I. Brunel and Professor Daniell.

Professor Wheatstone having been requested by the Committee of the House of Commons to explain to them the mode in which he proposed to communicate intelligence between two distant points, made the following answer:—

I have here a copy of the drawing of the specification to the first patent taken out by myself and Mr. Cooke; in all essential particulars, the instrument here represented resembles the one at the Great Western Railway. Here is what may be called a dial (see Fig. 1,) with five vertical magnetic needles. Upon this dial 20 letters of the alphabet are marked, and the various letters are indicated by the mutual convergence of two needles when they are caused to move; if the first needle turns to the right and the second to the left, H is indicated. If the first needle deviate to the right, and the fourth to the left, then B is indicated; if the same needles converge downwards, then V is pointed to. These magnetic needles are acted upon by electrical currents, passing through coils of wire placed immediately behind them; here is the representation of one of those coils, with the position of the magnetic needle with respect to it (Fig. 6). Each of the coils forms a portion of a communicating wire, which may extend to any distance whatever; these wires, at their termination, are connected with an apparatus, which may be called a communicator, (Fig. 1,) because by means of it the signals are communicated; it consists of five longitudinal and two transverse metal bars, fixed in a wooden frame; the latter are united to the two poles of a voltaic battery, and, in the ordinary condition of the instrument, have no metallic communication with the longitudinal bars, which are each immediately connected with a different wire of the line; on each of these longitudinal bars two stops are placed, forming together two parallel rows. When a stop of the upper row is pressed down, the bar upon which it is placed forms a metallic communication with the transverse bar below it, which is connected with one of the poles of the battery; and when one of the stops of the lower row is touched, another of the longitudinal bars forms a metallic communication with the other pole of the voltaic battery, and the current flows through the two wires connected with the longitudinal bars, to whatever distance they may be extended, passing up one and down the other, provided they be connected together at their opposite extremities, and affecting magnetic needles placed before the coils which are interposed in the circuit, there must be a similar complete apparatus at every different station.

"There is another very essential part of the apparatus I wish to mention, which is, the means we have of ringing a bell before the communication begins, in order to call the attention of the observer. The general principle of the alarum is this; to the detent of an alarum, on the ordinary construction of a clock alarum, a piece of soft iron is fixed, and opposite to it there is a bar of soft iron bent to the form of a horse-shoe; round this bent bar, wire, covered with silk, is wound, forming numerous coils; it is a property of soft iron to become powerfully magnetic when an electric current passes through a coil thus surrounding it. When the horse-shoe bar thus becomes magnetic, it therefore attracts the detent, and the bell immediately rings; when the current ceases the magnetic power ceases also, and the bell

Fig. 1.—Original Electric Telegraph.

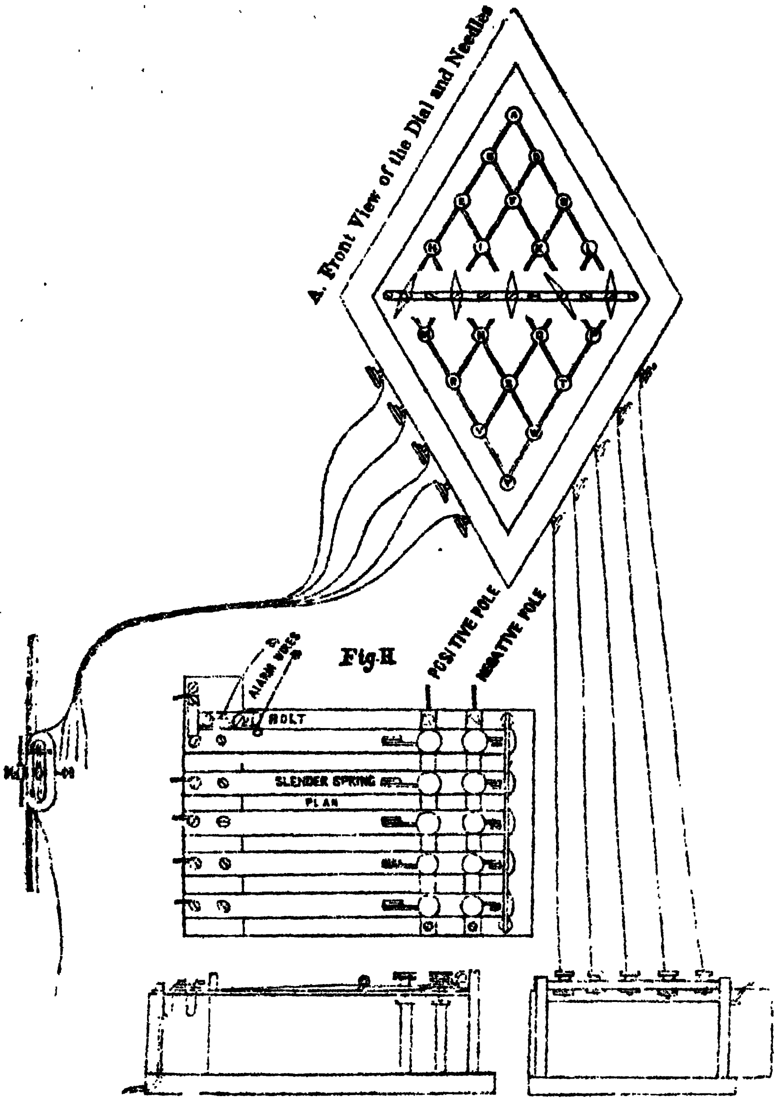

Fig. 2, Perspective view of a Tunnel.

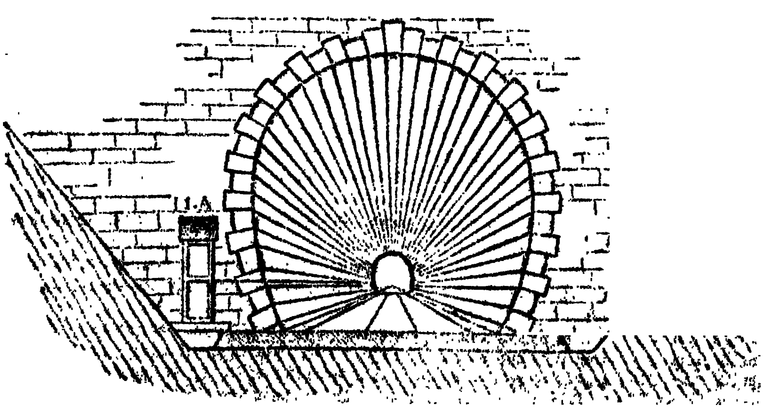


discontinues to ring. There are several other contrivances made to effect this purpose. Some other arrangements there are to which Mr. Cooke has [illegible] his attention, relating to the means of establishing communications at intermediate parts of the line where no fixed stations exist. To effect this, posts are placed at every quarter of a mile along the line, for the purpose of establishing a temporary communication with either of the adjacent stations; the guard of a train may thus carry with him a portable instrument, by means of which he can send up a message to a station either way, whenever it may be required. The wires are kept insulated from each other by a mixture of cotton and india rubber, which is a very good insulating material; then these prepared wires are all passed, with certain precautions, through an iron tube, which in some parts of the line is buried beneath the ground, and in other parts of the line is raised above it."

Lord Granville Somerset put this case:—"Suppose the Great Western Railway were completed between London and Bristol, do you contemplate the possibility of carrying your telegraph through the whole way, so as to signify from London to Bristol any thing you wish to communicate, and *vice versa* from Bristol to London?"—Professor Wheatstone replied, "The experiment has not been tried, but I have every reason to believe that it can be done. One very important circumstance I have ascertained is the little power requisite to produce this effect; it was formerly thought, that to send a current to any considerable extent very strong batteries must be employed, but in fact a very weak battery is sufficient, provided only it consist of a number of elements proportionate to the distance. So far as my experiments have gone, I think I should be able to effect a telegraphic communication between Bristol and London. Possibly several stations might be required, but, at any rate, the stations may be at far greater distances from each other than would be required for any ordinary system of telegraphs; my opinion is, that the intermediate stations will not be required."

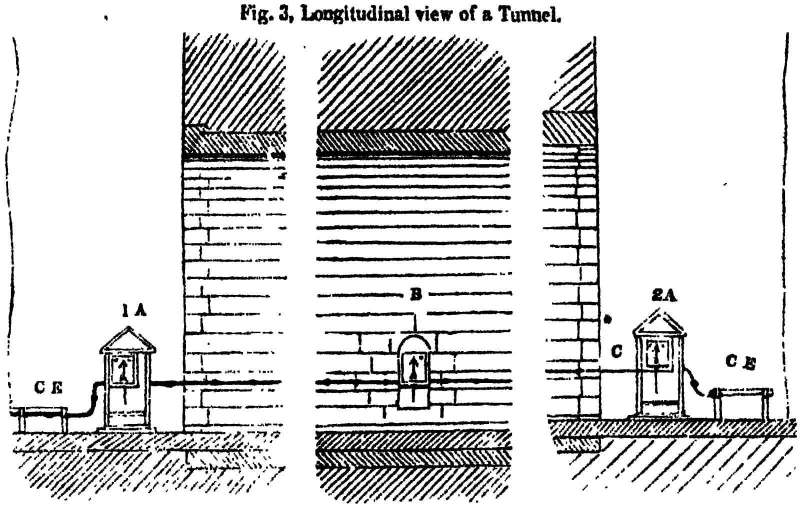
Mr. Loch asked whether there was any appreciable loss of time in making a communication from the Paddington station to the extremity of the line to which the telegraph is now carried? Professor Wheatstone: "From some experiments I made some years ago, published in the *Philosophical Transactions*, when I first turned my attention to the possibility of effecting telegraphic communications, I ascertained that electricity travelled through a copper wire at the rate of about 200,000 miles in a second; consequently there is no appreciable time lost in the communication of the electrical effect; the only time that would be lost would be at relay stations, if they were necessary."

Chairman: "Could you communicate from Dover to Calais in that way?—I think it perfectly practicable."

Professor W. added the following observations:

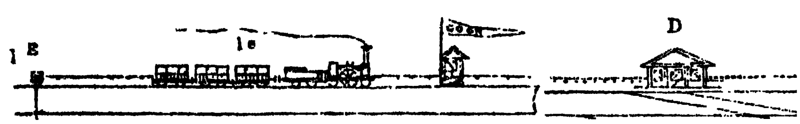
"An electrical telegraph offers a great many advantages over an ordinary telegraph; it will work day and night, but an ordinary telegraph will act only during day; it will also work in all states of weather, an ordinary telegraph can only work in fine weather. There are a great number of days in the year in which no communication can be given by an ordinary telegraph, and besides, a great many communications are stopped before they can be finished, on account of changes in the state of the atmosphere. No inconveniences of this kind would attend the electrical telegraph. Another advantage is, that the expense of the separate stations is by no means comparable to that of the ordinary telegraph; no look-out men are required, and the apparatus may be worked in any room where there are persons to attend to it. There is another advantage the electric [illegible] over the ordinary telegraph, viz. the rapidity with which the signals may be made to follow each other. Thirty signals may be conveniently made in a minute; that number cannot be made by the ordinary telegraph. There is one thing I will take the opportunity to mention—I have been confining the attention of the Committee to the telegraph now working on the Great Western Railway, but having lately occupied myself in carrying into effect numerous improvements which have suggested themselves to me, I have, conjointly with Mr. Cooke, who has turned his attention greatly to the same subject, obtained a new patent for a telegraphic arrangement, which I think will present very great advantages over that which at present exists. It can be applied without entailing any additional expense of consequence to the line now laid down, it will only be necessary to substitute the new for the former instruments. This new apparatus requires only a single pair of wires to effect all which the present one does with five, so that three independent telegraphs may be immediately placed on the line of the Great Western; it presents in the same place all the letters of the alphabet according to any order of succession, and the apparatus is so extremely simple, that any person, without any previous acquaintance with it, can send a communication and read the answer."

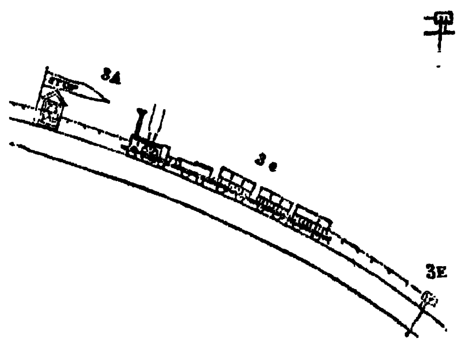
Fig. 3, Longitudinal view of a Tunnel.



Entrance. Interior. Entrance.

Fig. 4.—Application of the Telegraph to Crossings, &c.

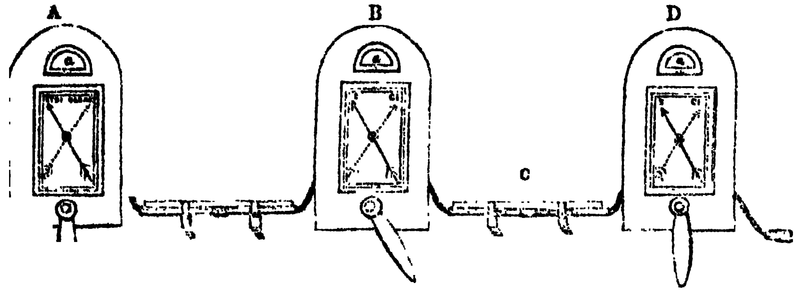




The drawings and letter-press description to which we have referred as recently published by Mr. Cooke, furnish (we presume) the further improvements referred to by Professor Wheatstone in the preceding evidence.

The annexed engravings (Figs. 2 to 11, inclusive,) are reduced copies of the drawings, and subjoined is Mr. Cooke's explanation.

Fig. 5.—Telegraphs for giving Two Signals.



Figs. 2 and 3 show the application of the electric telegraph to tunnels.

1 A, 2 A. Telegraphs fixed in policemen's boxes near the entrances of tunnels.

B. Intermediate telegraph near a shaft within a tunnel, always ready to work with 1 A, 2 A, in case of need.

C. Protecting tube for conducting wires.

C E, C E. Tube leading to engine-warner; *vide* Figs. 4 and 5 with explanation.

Fig. 4. Application of the electric telegraph to level crossings, approaches to stations, and switches, &c.

1 A, 2 A, 3 A. Telegraphs fixed in policemen's boxes, one or two miles from a level crossing or station.

C. Protecting tube for the conducting of telegraph wires, either carried on posts with a railing over it or under ground.

D. Telegraphs at stations or level crossings, corresponding with 1A, 2A, 3A.

1 E, 2 E, 3 E. "Engine-warners," (for details *vide* Figs. 5, 6, 7 and [illegible] by which an engine gives notice of its approach, at the distance of one or two miles, both to A and D, Fig. 5. If the station or crossing be clear, D replies to the policeman at A to allow the train to "Go on," or else to "Stop," [illegible] circumstances; the engine-man never venturing to pass A till [illegible] signal to "Go [illegible] even in case of his absence, the conductor would inquire by the telegraph A for permission from D to proceed. In the figure, the policemen at 1 A, 2 A, Fig. 4, have received permission from D (as is indicated by the pointing of the handles of the telegraphs at D, corresponding with the indications on the telegraph both at D and 1 A, 2 A,) to allow their respective trains to proceed. The policeman notifies in the usual manner, by the white flag, or signal that the line is clear. The train 3 e had been stopped by the policeman at 3 A, in obedience to a signal from the station D, in reply to the "warning" given by the engine of its approach from 3 E.

N.B.—The signal given from the "engine-warner" E, at A and D, is "Stop," accompanied by the ringing of an alarum. This signal remains till answered from D.

Fig. 5.—Telegraphs for giving two signals, as represented above at A, B, and D, each having an alarum (a), which sounds when a signal is given either from E, D, A, or B.

Thirty-one telegraphs, giving two such signals, are working from eight in the morning till ten at night, on the Blackwall Railway, between the stations and the termini, to direct the working of the fixed engines.

E represents the details of the "engine-warner."

An upright bolt passes through one rail of the "approaching" line of road, the upper end rising slightly above the rail, so as to be depressed by an engine or other very heavy body passing over it. The lower end of the

Terminal Telegraph.

Fig. 6

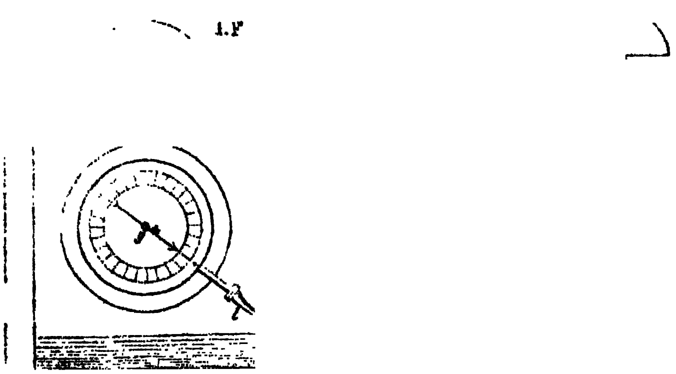


Fig. 8, An Intermediate and Portable Telegrap

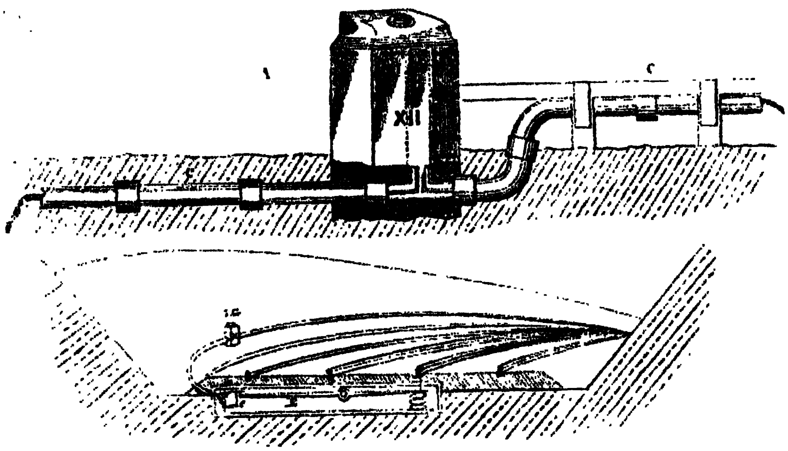
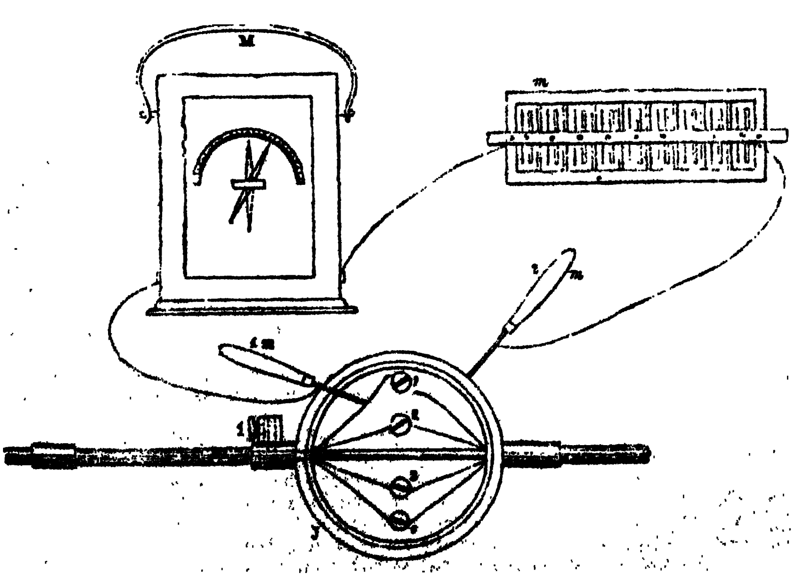
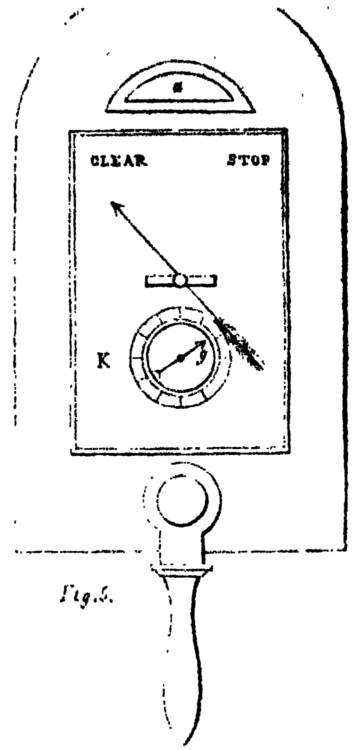


Section of Railway.

10, The Electric Detector, for detecting injury caused to the wires,



g. 9, Telegraph of a simple form.



bolt rests upon the arm of a lever supported by a spring capable of offering a resistance equal to at least half the pressure of one wheel of a carriage.

Upon a train passing, one arm of the lever is depressed, which, raising the other arm, breaks the electric circuit at e, and causes the alarum to be sounded and the warning signal to be given at A and D; the other wheels of the train produce no further effect till the warning has been replied to from D, which at the same time restores the electric circuit of the "warner" for another signal. Though the "warner" might be let off by mischievous persons with a crowbar, no inconvenience would be occasioned beyond arousing the expectation of the policeman for the time occupied by a train in passing the space between E and A, when the fact would be discovered, and reported by a signal to D. The object of the "warner" may obviously be attained by a variety of simple mechanical means.

Figs. 6 and 7.—Terminal telegraphs, for more extensive communications than those already described, giving 30 or 60 signals by the pointing of a revolving index-hand at letters on a fixed dial, as in a common clock; the person giving the signal turns the concentric hand *t*, till its pointer stands opposite the signal to be given, as shown in Fig. 6, when instantaneously, the index hand *g* in all the corresponding telegraphs in the circuit, viz. Figs. 6, 7, 8, &c. point at the same signal. Fig. 8 is an intermediate and portable telegraph, to be carried with each train, and applied, in case of need, to convenient arrangements at each mile-post or bridge along the line. The section of a railway below Fig. 8 illustrates this subject. An iron cap to the mile-post being unlocked and taken off, the portable telegraph is placed within a ledge fitted to receive it, making thereby the necessary connexions with the conducting wires, when it is at once fit for working with the "terminal telegraphs." This form of telegraph can be worked by any person at first sight, and requires no battery to be carried with it. It is fitted up with a water-proof cover and lantern, for rainy weather and night use.

N.B.—All forms of this electric telegraph are "reciprocal" in their action *i. e.* they give the same signals, in the working as in the recipient apparatus, and work equally from either end or from intermediate points.

Fig. 9 represents a very simple form of telegraph, on exactly the same principles as Figs. 5, 6, and 7, but combining the powers of both; the arrow giving two signals, for the purposes explained when applied to tunnels, level crossings, &c., and the small index K being adapted for a more extensive communication, when circumstances require it.

M. Detector, for detecting [illegible] ed to the pipe or with each other, fracture, or water.

m, is a small battery; 1 m, 2 m, are "feelers," in connection with the battery and detector. Whenever these feelers touch each other, an electric current passes from the battery and influences the index of the detector M, by turning it on its axis. J J are iron boxes which occur at short intervals along the line, each fitted with a screw lid, and so connected as to render them continuous with the tube C. The terminations of each length of wire rope one introduced into the box and each wire screwed with its fellow to a piece of wood fitted to the bottom of the box, so that the wire marked 1 is continuous throughout its length and always connected by the screw 1, by which it can be recognized at every box along the line. The openings by which the wires enter the box are hermetically sealed with composition; but a small tube passing through the box admits of a free communication of air from a distant reservoir. Suppose wire 1 to have become in partial contact with the tube, either by the metals touching or the presence of water: upon opening the box at which the wire is to be proved, the screw 1 must be taken out, and the feeler 1 m brought in contact with one end of the separated wires, the other feeler being kept in contact with the pipe. If this portion of the conducting wire is sound, the detector needle remains stationary; but upon removing the feeler, 1 m, to the other liberated end of wire, the detector index moves on its axis, and indicates on the graduated scale the degree of contact existing between that portion of the wire and the tube. Supposing the experiment to be tried again at the next box, and the contact proved to lie between the two boxes, the intervening faulty portion of wire is exchanged for the sound wire marked 0, (which is a spare wire introduced by such repairs) by this means the wire 1 is again restored to soundness; it is obvious that different portions of the spare wire, 0, may thus be employed to repair a damaged wire, at numerous short intervals along the line, without rendering it necessary to disturb the line generally; the minutest changes in the insulation of the wires from dampness, &c., can be detected by this valuable instrument, and corrected by blowing through the pipe a draught of dry air from the reservoir.

When a length of wire-rope has to be removed, in consequence of accidental injury, the connecting screws in the boxes at each end of the length are taken out, and one end of the wires to be removed is bound to the end of a fresh length of wire-rope conveniently wound upon a drum. The further end of the faulty length is then drawn out of the tube and wound upon an empty drum, as the new rope gradually takes its place. The screws again unite the ends of the wires, and the line is restored. The faulty length of wire, after undergoing examination and repair, is again fitted for use.

Each wire is separately covered with cotton and India-rubber solution, and the set of wires made into a rope, which is passed through a hot resinous varnish before being introduced into the tubes.

Fig. 11.

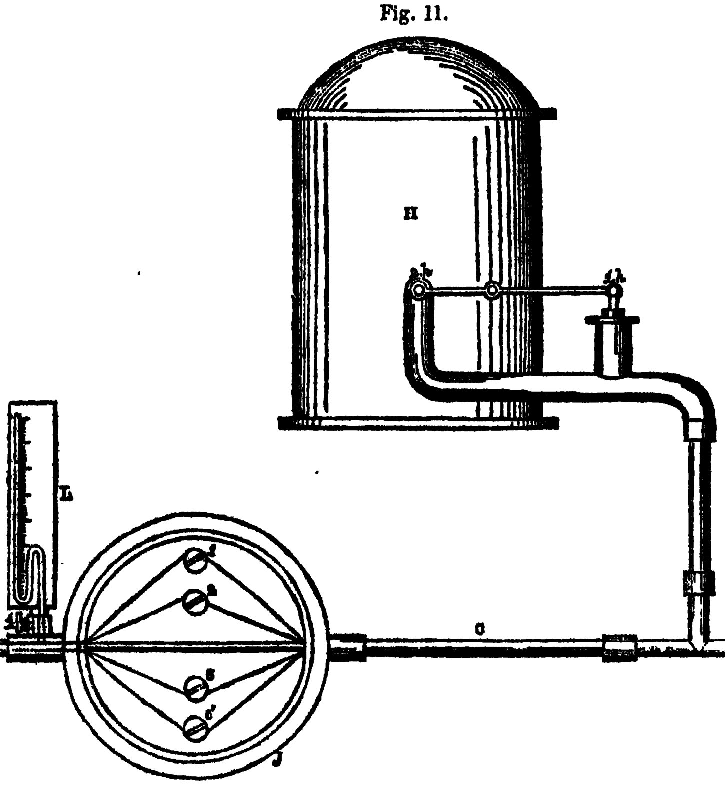


Fig. 11. Air-pressure apparatus, employed for excluding water from the tube, when carried underground; and for giving notice of defects in the tubing.

H is an air-pressure apparatus, or air reservoir, of convenient size, charged with dry air to any pressure. 1 *h* is a pressure balance, in the form of a lever; 2 *h* a valve communicating, by a minute opening, between the reservoir H and the protecting tube C. Suppose it to be found desirable to keep the interior of the tube under a pressure of two or three pounds (that being calculated as sufficient to exclude the greatest pressure of water to which the tube is liable), the balance 1 *h* must then be loaded to that amount; on any escape of air taking place from the tube, the lever arm, 1 *h*, would descend and open the valve 1 *h*, till the high-pressure reservoir had increased the pressure of the tube, which by raising the pressure-balance 1 *h*, would close the valve 2 *h*. A barometer, L, may indicate the change of pressure either in the reservoir or tube. The reservoir is supplied by an air-pump, when nearly exhausted by any leakage, which, under the light pressure of two or three pounds, should be very trifling. Should the barometer, however, indicate a sudden escape of air, attention must immediately be directed to the proving-boxes J, which occur at short intervals along the line.

In or near the box, conveniently connected with the tube, is a three-way stop-cock, to the pipe of which a portable barometer or detector, L, can immediately be applied. When the tube is faulty, upon turning the cock in one direction, the pressure on the barometer will remain steady, but in the other direction it will rapidly diminish, from the escape of the air. By proceeding with a similar experiment at other proving-boxes, the two boxes will be readily ascertained between which the escape of the air takes place; when the tube lying between the last proved points must be carefully examined to discover the faulty part.

THE ARTESIAN BORING AT PARIS.

In the Journal for April last, we gave an account of the successful operations in sinking the Artesian well at Grenelle; we are now enabled to furnish some farther detail of the geological formation through which the boring passed, from the observations of M. Mulot given in the *Revue Générale*, together with some additional information as to the size of the bore, and the geological character of the circumjacent country.

Table of the depths of the strata measured from the surface in metres and reduced to English feet.

Metres.	Feet.	
10	33	Alluvial formation, the former bed of the Seine.
41	134	Plastic clay and quartzose sand.
140	459	White chalk with black flints.
165	541	Gray chalk and flint.
506	1660	Gray chalk, very hard, with layers of micaceous clay.
546	1791	Blue clay, green clay, micaceous black clay, with fossils and iron pyrites.
547	1794	Argillaceous green sand.

Beyond here the sand continues and has not as yet been quite explored, it is in this stratum that the water is obtained.

The boring was commenced at a diameter of 0·51 metres (20 inches) and diminished by degrees as the tubes descended, the first four columns of tubing diminishing in just [illegible] to the depth of [illegible] metres (576 feet); at this point

A 5th column of tubing goes down to 350 metres (1148 feet), with a diameter of 0·26 (10 inches.)

A 6th to 410 metres (1345 feet) diameter 0·21 (8¼ inches.)

A 7th to 540 metres (1771 feet) diameter, 0·17 (6¾ inches).

The last 7 metres (23 feet) are not tubed.

The fixing of the ascensional tube is always an operation very important and delicate, and will on this occasion in particular present serious difficulties. Indeed one would suppose that it was almost impossible to lower perpendicularly a tube 547 metres (1794 feet) high into the earth, but from M. Mulot's skill, of which he has given so many proofs during the work, we are completely assured of its final success.

The quality and kind of metal which composes the ascensional tube have been studied by persons interested in the construction of the well; for many tubes of this kind have been constructed of wrought iron, and have not answered the expectations of the parties interested. A remarkable instance may be cited which happened at Saint Cyr, near Tours, at Dr. Bretonneau's artesian well. The water there rises from the sand beneath the chalk, and was tubed with iron, yet every successive year the quantity of water was sensibly diminished, and at last gave only an insignificant supply. M. Bretonneau caused the tubing to be drawn up, and although it had at least a thickness of 8 millim. ($\frac{3}{10}$ of an inch) and was well preserved, yet at the joints of each pipe there was one, and sometimes several circular holes two and even three centim. diameter, (about an inch diameter,) of which the edges were perfectly sharp, as though they had been cut out by a pair of nippers. This phenomena was probably due to an electro-chemical and it shews that iron ought to be entirely rejected in the construction of ascensional tubes. Tubes of oak or elm are certainly those to which preference is always given; but the thickness which is indispensable for them, would diminish the interior diameter too much in the Grenelle well. Copper tubes of a thickness of two or three millim. (about $\frac{1}{10}$ of an inch), not only possess a sufficient resistance, but also the property of being indestructible. It is with these latter, therefore, that the Grenelle well is to be tubed.

Independently of the importance of M. Mulot's undertaking for the useful purposes to which it may be applied, it is also of great interest for the geological study of the strata through which it traverses with regard to the central heat of the globe. Taking as our starting point the constant temperature of the cellars of the Observatory, which are 28 metres (91 feet) deep, the temperature would present a uniform increase of a degree centigrade for every 32 metres (105 feet) in depth. The temperature of the water of this well has been calculated at about 27·6 Cent. (8·17 Fahr.)

The cretaceous formation, passed through by the well of Grenelle, has been deposited in successive layers in an immense basin, formed by the formations anterior to this part of the secondary formation; the borders of the inferior strata of the chalk formation, crop out in many places, some on the edges of the basin and others a little below the soil; they not only receive the infiltrations of the rain water, but also those of rivers that flow over the exposed strata. A complete identity has been found to exist between specimens of brown free stone and green sand obtained in very different places, and very far one from another, and specimens from M. Mulot's boring. At Lisieux in Normandy, the inferior part of the cretaceous formation reposes on the Jura formation;—the limit of which formation extends towards Mans and La Flèche, and receives in this part considerable infiltrations from the Loire, which flows direct upon it N. E. of Angers. The Loire ought also to furnish water to the lower part of the formation near Saumur; the boundary then passes south of Paris by Loudun, Châtellerault, to the north of Bourges, and then to Sancerre. In all these different localities it receives the waters of the Vienne, Creuse, Indre, Cher and Loire; at Sancerre this limit takes a north-east direction passing near Auxerre, Joigny, and Troyes, and receiving the waters of the Yonne, Seine, Aube, and a great many other rivers of less importance. Near Troyes,* at Lusigny, and at the Abbey of Monster-Rancey, at four leagues south-east of Troyes, the brown free stone and the green sand crop out. In its northern direction through Sainte-Menehould this boundary receives the waters of the Aisne very considerably. Lastly, this formation forms the bottom of the tertiary formation of Belgium, where it receives other infiltrations that feed the Artesian wells of Picardy and Artois, &c.

All these waters filter freely enough through the sand of the cretaceous formations, and from thence pass and accumulate at the bottom of the basin, continuing to be in direct communication with the points of infiltration. As these points are so much elevated above Paris, the waters rise, and will rise still more in the Grenelle well when it is completely tubed, to a height which will be a measure of the amount of pressure exercised on the layer which forms as it were the roof of the bottom of the basin.

ON THE GIVING WAY OF EMBANKMENTS.

The following remarks on the giving way of embankments, by M. Colin, principal engineer of the bridges and embankments of one of the largest canals in France, are the results of many years practical acquaintance with the subject.

The first appearance presented by a slope that has given way is that of an alteration more or less complete of its primitive form, whether natural or artificial. On examining the facts which strike the eye of the observer it must be at once admitted that the cause of the fall of a mass of moving earth must have operated either at a certain depth, or near the surface of the slope; therefore it is requisite, in all cases, to distinguish the superficial slips of earth from those that have a deeper origin.

When a mass of homogeneous earth is composed of argillaceous matter, which is liable to give way, the strata may be more or less inclined to the horizon. When the slip occurs on a pre-existing surface, the following considerations will not be applicable; the slips of this kind are very rare, and are only accidental occurrences, which we should be careful not to confound with the general facts examined by M. Colin.

The mass of fallen earth whether natural or artificial, could not have been in a state of equilibrium in relation to the cohesion of its particles, which on the one hand tended to hold it together—and to gravity, which, on the other hand, tends to destroy the cohesive attraction. When this equilibrium is destroyed it must happen that the slope, or a part of it, will experience a spontaneous fall.

When by the action of the fall the moving mass is detached at such a depth that it preserves its central cohesion notwithstanding the fracture, which has destroyed the cohesion only on the surface of the slip, and notwithstanding that relative alteration in the angle of the strata which compose that mass,—in such case the cause of the slip must be pronounced to have proceeded from below, in contradistinction to [illegible] when the moving mass is detached nearer the surface, and when the cohesion of the mass is more or less destroyed by the action of external agents. It often happens, however, that both these kinds of slip occur at the same time.

This characteristic difference depends on the chemical nature of the soil, so that the same kind of slope may in one case experience a falling away from the surface alone, when in another case the cause of the slip may be more deeply seated.

There is another important difference between slips of earth proceeding from the surface and from below, which is, that the extent of the former is immediately known, while that of the latter may go on gradually increasing, according to the influence of rain, frost, and thaw. In every case, however, it is the action of gravity which causes the disturbance of the equilibrium; for the destruction of cohesion by the external agents is only an action eminently statical; the force of gravity alone causes the movement. It is therefore natural to infer, that as the principal cause of the destruction of the equilibrium is the same in all cases, the dynamical results must also be the same. Consequently the surfaces of slips, whether they proceed from below or from the superficies, ought, theoretically speaking, to be of the same kind, and to present, as regards their material points, a striking resemblance.

On examining with great care the general facts concerning these two kinds of spontaneous slips of earth, the angle of inclination of the falling earth, and that of the surface on which it falls, and comparing them with a great number of facts collected in various places, with different kinds of soil, and under different circumstances, by other engineers, as well as by M. Colin himself, he thinks he has established as a principle the following proposition:—

"When masses of earth nearly homogeneous, whether natural or artificial, are composed of such materials that the action of gravitation may, under the influence of certain physical circumstances, overcome the cohesion of their molecules, the results are spontaneous movements, which are called slips. These movements are independent of the height of the slopes on which they occur; they always present, nearly in the same degree, the character which appertains to them; lastly, and above all, the natural surface of separation, or the surface of the slip, has no pre-existence, and possesses a constant and regular form, which approaches more or less exactly, according to different circumstances, to a surface of a cycloidal shape, which brings the causes of its formation essentially within the domain of mechanical science."—*Inventors' Advocate.*

HEREFORD CATHEDRAL.

The public are already aware that very extensive improvements have for some time been going on in this beautiful edifice under the superintendence of Mr. Cottingham, the celebrated architect. We have already described the various restorations in the choir, Lady Chapel, &c., but all the interest in these (and it has been very great) is altogether lost in the discovery by the architect that the tower of the cathedral, with its immense superincumbent weight, is in imminent danger of falling, and crushing the mighty fabric in one general ruin. Before entering into a somewhat technical description (which may perhaps be understood only by a few) of the appearances that lead to this conclusion, we may observe, that we have examined the present state of the tower most minutely, and the fissures in the masonry at the angles of the Norman arches of the transepts are truly frightful. In some places the workmen may insert a piece of wood or any implement to the depth of two feet; and we particularly noticed that one of the stones forming the masonry had given way, not at the joining, but in the solid part itself, being literally split in two. It appears that some cracks in the chief wall of the tower led Mr. Cottingham to examine into the cause. He accordingly proceeded first to ascertain the state of the main piers below in the body of the church, and these he found to be all solid. He next explored the masonry of the unsightly piers under the Norman arches of the north and south transepts, and ascertained that the arch was quite independent of this enormous body of masonry; that is, that the Norman arch had "stuck firmly to its work," and that, as has long been suspected, the piers were no support whatever. Mr. Cottingham next examined the string course round the bell chamber, which supports the 52 solid stone columns above that chamber, and he found that this course (or wall, as we should call it) was rounded in the centre, and dipping down at the angles of the tower. This proved that the ancient Norman arches were still in their original position, and that the fractures which now exhibited themselves in every direction were occasioned by some defect in the main piers of the tower. On taking up the bell-ringers' floor, Mr. Cottingham found the stone groining (which was put up about the time of Edward IV.) also pressing upon the four angles of the tower. It is singular that the "pockets," or angular spaces of this groining, were filled up to the level of the floor with solid rubbish. On removing this, a most extraordinary failure in the masonry fully developed itself. At each end of the four angles was a hollow chamber running diagonally through the main wall, which, from the pressure of the enormous stone piers above alluded to, was crushing in in every direction. All the bond of the interior ashlaring was ascertained to be broken, and the stones fractured into innumerable pieces; indeed, the failure is awful to contemplate, and we may congratulate the public that the discovery was made previously to any further pressure, which must have occasioned the total destruction of this magnificent tower, together with the choir, the transepts, and the eastern portion of the nave. When, or

* The specimens from Lusigny were presented by M. Volfardric, who observes that the height of the well above the level of the sea is 130 metres, whilst that at Paris is only 31 metres.

under what circumstances, so awful a catastrophe would have occurred, of course not even those best acquainted with the subject could pretend to describe. Mr. Cottingham has caused about 150 wagon-loads of rubbish to be removed from the tower in order fully to ascertain its state, and there can be no doubt that the measures he intends to adopt will give full security. One great advantage, too, of his plans will be to expose the 52 stone columns of the tower (a remarkably fine piece of masonry) to the view of persons in the church. In the mean time, so imminent does he consider the danger, that he will not suffer the bells to be rung, and all attention to the other parts of the works is suspended until satisfactory reparation has been made. The restoration will now be effected at a comparatively trifling expense; had the discovery not thus timely taken place, the cost would have been enormous. It is worthy of remark that so little were these subjects understood only a comparatively short period ago, that the western front was declared to be secured for hundreds of years, and yet in six weeks only from the time of that declaration it was a mass of ruins.—*Hereford Journal.*

LIVERPOOL DOCKS.

It will be recollected that in the last February number of the Journal, we gave a letter of Mr. Hartley's, the Dock Surveyor, addressed to the Liverpool Dock Committee, in consequence of certain charges being brought against him by a Member of the Committee, whereupon a Sub-Committee was appointed to inquire into the charges. This Committee have lately made their report which is now before us, we are happy to announce, what we feel assured the whole of the profession were prepared for, that it completely vindicates Mr. Hartley from the charges. The report is too long for insertion in our Journal, but the following announcement we are sure will be all that is necessary for us to give.

"The sub-committee, having personally examined the accounts at the Dock-yard, and the system of checks on labour and expenditure of stores, are unanimously of opinion, after a very strict investigation of the stock accounts, and careful examination of the books, which show in detail the expenses incurred in every department of work, and making allowance for the expense of the establishment and maintenance of a large stock, that the various works have been executed on very reasonable terms, and at lower rates than they could have been in any other way. The interests of the Dock Trust, in the conduct and management of the mechanical departments of the Surveyor's establishment, have been materially promoted by the system which has been pursued; and, as long as that system is kept up in the same orderly, vigorous, and efficient manner, no better system can be devised for the general benefit of the trust, the establishment being highly creditable to the Dock Surveyor, *whose indefatigable zeal, honour, and industry cannot be too highly commended.*"

Removal of Sunderland Light House.—At a late meeting of the Commissioners of the river Wear, the taking down of the Light House being discussed, as part of the plan of building the new North pier at the mouth of the harbour, Mr. Murray, the engineer, suggested the removal of the Light House, in its present entire state, to the eastern extremity of the new Pier, a distance of about 420 feet, so as to make it serve the double purpose of a stationary and a tide-light. Mr. Murray exhibited a model of the building, and after explaining how he proposed to effect this undertaking, the Board decided that he should proceed forthwith to remove it. This Light House was erected about 40 years ago, by the late Mr. Pickernell, then engineer to the Harbour Commissioners. It is wholly composed of stone; its form is octagonal, 15 feet in breadth across its base, 62 feet in height from the surface of the pier to the top of the cornice, where it is 9 feet in breadth across, and the top of the dome is 16 feet above the cornice, making a total height of 78 feet; and its calculated weight is 250 tons. Mr. Murray intends to cut through the masonry near its foundation, and insert whole timbers, one after another, through the building, and extending 7 feet beyond it. Above and at right angles to them, another tier of timbers is to be inserted in like manner, so as to make the cradle or base a square of 29 feet; and this cradle is to be supported upon beazers, with about 250 wheels of 6 inches diameter, intended to traverse on 6 lines of railway to be laid on the new Pier for that purpose. The shaft of the Light House is to be tied together with bands, and its eight sides are to be supported with timber braces from the cradle upwards to the cornice. The cradle is to be drawn and pushed forward by powerful screws, along the railway above mentioned, on the principle of Morton's patent slip for the repairing of vessels. However surprising the removal of such a building may appear to many, yet in New York, for some years past, large houses have been removed from their original situation to a considerable distance, without sustaining any injury. The immense block of granite, serving as the pedestal of the equestrian statue of Peter the Great, at St. Petersburgh, was conveyed four miles by land, and thirteen by water. Several Obelisks have likewise been transported at different times from Egypt to Europe; and lately, one was conveyed from Thebes, and erected by the French at Paris. But the fact that the Light House on our North Pier is composed of stones of comparatively small dimension, its great height, and small base, make the operation of removing it much more difficult than any thing of the sort ever attempted. We heartily wish the enterprising engineer every success in his bold and novel undertaking, which is to be carried into execution in the course of a few weeks from this date.—*Sunderland Herald.*

COMPETITION FOR THE MARSEILLES EXCHANGE.

The following conditions of competition for designing an Exchange at Marseilles, we have translated from *Revue Générale de L'Architecture.*

1st. The situation will be chosen in a *perimètre* commencing at the "Rue de la Prison," and proceeding up to the "Place de Justice," the Grand Rue as far as the Courts.

2nd. The competition designs must contain, not only the Exchange strictly so called, but also the Chamber and Tribunal of Commerce, the syndicat of the money-changers, the royal brokers, the merchant counsel, and all the necessary appendages to these, such as peristyle porticos, vestibules, vestries secretary's office, registry office, bureaux, counting houses, &c. &c. Also a dwelling place for the porter, a guard-house for a detachment, and a place to deposit cloaks, umbrellas, and walking sticks.

3rd. The great hall of the Exchange, including the interior porticos must contain at least 3000 persons, and consequently have a superficies of not less than 1000 square metres.

4th. The drawings must be done with care, the sections to be in a pale colour, the horizontal sections in Indian ink, and carmine for the vertical sections, yellow for the wood, Prussian blue for the iron, grey for the metallic roofs, and brick red for the tile roofs.

5th. Each design must be composed of the following separate pieces.

1. An explanatory and justifiable report.
2. A general plan of the whole.
3. A plan of the ground floors at one or two metres above the level of the great hall, and the same of the first floor.
4. Longitudinal and a transverse section through the interior of the edifice.
5. Front and back elevations.
6. Profiles and details of execution (this need not be paid so much attention to).
7. A descriptive device containing a scale of the works, and the cost after the current price of the country; the whole exactly and summarily expressed.

6th. As to the order of architecture, the best in whatever order it may happen to be chosen, and even the several orders may be blended, but keeping at the same time a tone of convenience, solidity, elegance, good taste, a noble simplicity, and a wise economy.

7th. The scale of the general plan to be, 2 millimetres to a metre, that of the sections and separate plans a centimetre to a metre, and that of the details of execution 5 centimetres to a metre.

8th. The competition is fixed at six months date from the 1st April. During the following fortnight the competitors to deposit their designs at the secretary's office, at the Chamber of Commerce, where they will receive a certain number according to the order of presentation, the names and address of the competitors must be enclosed in an envelope carefully closed, to which the same number will be affixed. Each competitor to have a receipt stating the formal deposition, the number of plans, and the particular number given them, but without indicating name or person.

9th. When the term for the preparation of the plans has expired, the designs will be submitted to the judgment of a committee chosen from the members of the Chamber of Commerce, and an equal number of artists. The decision will not be definitive until the sanction of competent authorities be given, and then the names only of the authors of the three best designs will be announced.

10th. The first design will receive the prize of 3000 francs (120*l.*), and then, without further remuneration or honours, will remain the property of the Chamber, who will have the right to alter it at their will, and to confide the execution to whom they please. The names of the other two authors of the second and third best designs will be honourably mentioned.

11th. Every design (No. 1 excepted), will be restored to their authors, as well as the sealed envelopes containing their names, on the production of the previously delivered receipts.

Marseilles, March 30, 1841.

CANAL STEAMER FITTED WITH MR. P. TAYLOR'S REVOLVING SCREW PROPELLERS.

On Wednesday the 5th of May, we had the pleasure of inspecting a new steam boat on the river Irwell, fitted by Messrs. Peter Taylor and Co., of Hollinwood, near Manchester, with steam engines and propellers of an entirely new construction, both inventions of Mr. Peter Taylor, and for which he has obtained patents. The vessel is 75 feet long and 10 feet wide, and built (with the exception of the gunwale and paddle-box,) entirely of iron. She appeared to perform very satisfactorily; at a speed varying according to the depth of water from about eight to nine miles per hour, which upon a confined water we believe has never been attained by any steam vessel. In noticing a trial some months ago of another vessel belonging to Messrs. Taylor and Co., which had then been newly fitted with similar propellers, we gave a description of the apparatus, which consists of a number of continuous curved vanes or segments of screws, or wings on two axes. In the instance now under notice five pairs are affixed upon one axis, and five pairs upon the other; the number being regulated by, and varied according to, the power of the steam engines and the extent of surface of the vanes or blades, which have the appearance of small windmill sails, and have been very appropriately named *revolving screw scullers*: each set consisting of five pairs are six feet in diameter. The vanes of one set work betwixt the vanes of the other in the same manner as the teeth of cog wheels; by this arrangement the two sets, although six feet in diameter, are together contained in a paddle-box (there being only one): it is 9 ft. 8 in. in width, and placed at the stern of the vessel; the smallness of the space occupied offering great convenience for passing locks.—The scullers are well protected from the banks or sides and bottom of the canal, with which it is almost impossible they can ever come in contact. The paddle-box occupies seven feet in length, and has the effect of extending the boat so much. The width or breadth is regulated by the width or breadth of the boat, which in the present instance is 10 feet outside. The two shafts or axes are placed at an equal distance from each other, as well as at equal distance from the sides of the boat or box containing them, and with which they run parallel; and as we have before observed, the shafts or axes are so arranged in respect to each other, that the vanes or oblique surfaces of the one can enter between the vanes of the other shaft or axis; thus obtaining a great extent of propelling surface within a very confined space. The axes are placed considerably above the water line, and the curved oblique vanes or scullers are affixed upon the shafts or axes in opposite directions, that is, they are affixed upon one shaft or axis in such a manner that they may be said to form parts of a right-handed screw, and upon the other shaft or axis, so that they may be said to form parts of a left-handed screw. This novel propelling apparatus is worked by a pair of *semi-rotatory steam engines*, also Mr. Taylor's invention. The steam boiler is of the same description as those used upon the railways. It is placed towards the stem of the vessel, and the steam engines close up to it. To one axis of the propelling apparatus is coupled a shaft, which runs lengthwise to the steam engines. The starting, reversing, and stopping apparatus is connected with the regulator of the steam engine, and affixed at the stern of the boat, within reach of the steerer, who manages the whole when necessary. This is a most simple and beautiful arrangement, the helmsman being altogether independent of the engineer. He can start, stop, or reverse the engines at his pleasure. The helm or rudder is placed in the usual position, and is immediately behind the propellers.

The vessel has been engaged during the last month on the Bridgewater Canal towing boats; at one time she towed six boats, their united cargo being equal to nearly 600 tons, at the rate of three miles per hour, and at another time she towed four fly boats equal to 60 tons, a distance of six miles in one hour 16 minutes.—*Manchester Times.*

BENEVOLENT INSTITUTIONS OF THE ENGINEERS.

Since the notice which we gave in our last, the promoters of the plans for giving relief to the members of the profession and workmen employed by them, have succeeded in organizing an institution for each of their respective objects. That for the relief of distressed engineers has received the countenance of the Institute of Civil Engineers, and the Society for the workmen goes on, receiving increased support from the mechanical engineers, who we trust will give every support to an object so well deserving; a subscription list is now open, it has been, we are happy to say, liberally signed by the masters.

KING'S COLLEGE.

We are glad to learn that the department in King's College hitherto devoted to engineering, and to the mechanical and manufacturing arts is about to be extended, so as to embrace also the principles and practice of architecture. The existing provision in King's College for the education of the engineer having also drawn thither students in architecture in search of instruction adapted to their pursuits, the desirableness of the proposed extension became evident. King's College is then likely to be the first collegiate establishment to undertake the preliminary education of the architect as such, as well as in literature and science generally, and we cannot doubt of its success in so doing, nor of the good that will be thereby effected both to the profession and to the public.

Monument in Westphalia.—A remarkable monumental structure is at present raising, or about to be raised, in that part of Westphalia where Arminius overthrew the Roman legions, commanded by Varus, to commemorate that event. The monument is to consist of a statue of the German hero, similar to the many images which may still be seen under the name of "Ermin Saulen," in various parts of Germany, and which became, in the early periods of the Christian era, objects of idolatrous worship. The statue is to be of copper, 42 feet high, and to the point of the uplifted sword 75 feet! It is to be placed on a circular temple 90 feet in height, on the top of the hill Teut, in the Teutoburger forest. The monument promises to do honour to German art, and the idea of erecting such a work is a proof of the patriotic feeling of the Germans. The expenses are to be defrayed by subscription, and all the sovereigns of Germany have contributed.

SEVERN NAVIGATION IMPROVEMENT.

Abstract of the Engineering evidence for improving the River Severn, given before the Committee of the House of Commons, on the Bill, May 5, 6, 7, 10, 11, & 12, 1841.

Mr. E. L. Williams, Engineer, was examined and stated that the fall in the Severn is slight compared with the Thames. The fall in the Thames from Abingdon to Henley is 2 feet per mile. The fall in the Severn in this district is about 9 inches per mile. On the Thames also there were the conflicting interests of millers and others who had private rights connected with the water which was not the case with the Severn. The operations on the Thames have been to the benefit of the navigation. The course of the Severn is comparatively straight, and its width comparatively uniform, which circumstances are favourable for our operations. I attribute the shoals of deposit to variations of width. There is little tide above Gloucester, and this will not affect us. Our first weir is below Upton. We propose there to make a lateral cut, with a lock in it with a lift of five or six feet. Between Upton and Gloucester below the lock we propose to equalize the area, or water-way of the river, by contracting it by embankments in certain parts and widening it in others. The effect of contracting it will be to preserve clear what we have dredged. We shall contract the area by decreasing the width and lining the banks with stone. I have experience of the natural way in which the water-way is preserved. The finest channel in the river is from Sandy Point to the Mythe Bridge near Tewkesbury, which preserves the water-way throughout from the quality of the sectional area. I infer that if we form the same results we shall produce the same effect. The average depth there at low summer water is from 10 to 12 feet throughout. I anticipate that the artificial banks will be principally confined to the district between the Mythe and the Haw Bridges. This space includes the Deerhurst and other shoals which we propose to dredge. I have here the sections of what we propose to do. The first shoal of importance we propose to dredge is at Gloucester, in the eastern channel alongside the Quay at Gloucester, extending from the lock of the Gloucester and Berkeley Canal to the other bridge. In fact we propose to dredge to a trifling extent from the Westgate Bridge to Sandhurst, a distance of two miles. In the western channel we propose to dredge sufficiently to allow canal boats to enter the Gloucester and Hereford Canal. We then come to Wainlode Hill; there is not much dredging to be done there. We then come to the Haw, which is laid down for dredging to a certain extent, but not requiring the shoal to be taken out. There is a section laid down for the other channel, and there is sufficient water for the purposes of navigation under one arch of Haw Bridge. We then come to Deerhurst, where the area is to be equalized and the channel dredged. At Sheplock we do the same thing; also at Lower Lode up to Cumberland, where similar operations are required. We then come to Bushley Reach and Saxon's Lode, where we dredge and equalize the area. Then we come to Upton, where we make our first lateral cut. There will be no interruption to the navigation while the cut is being made, and when the weir is being made the lock will be open. The lock will be 20 feet wide, 100 feet long, with 5 ft. 6 in. lift. We then place our weir obliquely to the current, about midway between the upper and lower entrance. The length of the weir is 600 feet. It will be constructed with sheet piling and rubble stonework. The height of the weir above the surface of the present bed of the river will be seven feet. The effect of this weir will not prejudicially affect the drainage of the surrounding district. I have surveyed the falls of the lowest drains in the district, and find the lowest will be above our permanent water line. This answer will apply to all the drains throughout our operations. I have taken the greatest pains to satisfy myself on these points. We do not raise the water there in any way; and I believe the effect of the works will be to expedite the passage of flood water and not to detain it, because we clean out the channel. Above Upton we do raise the level of the water in some places, but in all cases it will be below the drains. I have made a section of Lord Sandy's drain. I find there is a fall of 9 feet in the first 100 yards of the land drain. The drain itself is below the weir, and consequently cannot be affected by it. We then come to the shoal at Ryal Watering, and take a little off the top of it by dredging. At Hanley we do not dredge, as we shall get sufficient water from the pound to pass over. Dredging with simultaneously pounding back the water would produce a bad effect. At the Rhydd we take the top of the shoal off. At Clevelode, Pixham, and Kempsey, we do the same. These are the shoals mentioned as affected by dredging. We then come to the Ketch shoal, which is to be dredged. The Silver Ford shoal is to be dredged slightly. We then come to lock No. 2, which will be similar to the previous one, a cut with a lock in it, each of the same dimensions as the other, with a lift of 7 ft. 6 in. and a weir. The water is penned back sufficiently at Upton Bridge by the shoal; the height of the weir will be 11 ft. 6 in. from the bed of the river, the length 400 feet; it will also be placed at a sharp angle, and constructed in the same manner as the other; the piles are elm, oak, and fir. After the water has passed over the dam of sheet piling, it will fall on a dam of stone work, and we thus prevent a pool there; this will remove the obstructions immediately above. We have now passed Worcester and are come to Bevere Island, where is our third lock; the river there divides itself into two branches, which supersedes the necessity of an artificial cut, and we deal with it as such, placing a lock of the same dimensions in one branch and a weir in the other; the lift is 4 ft. 6 in., the length of the weir is 400 feet; it will be placed obliquely as the others; with some trifling dredging this is sufficient up to Holt, where we have another lock, No. 4. The length of the proposed cut is about a quarter of a mile on the Ombersley side, on Lord Sandys' property. I know of no damage that the estate can suffer by our taking that bit of ground. Our works will not be in sight of Ombersley House, which is a mile and a half to the left; the length and construction will be the same, the lift 4 ft. 6 in.; the locks will be built of brickwork; the length of the weir there will be 880 feet, the height 7 feet from the bed of the river; the obliquity is to give facility to the passing of the water, this will [illegible] dredging except very slightly up to Lincombe Hill, where is our fifth and last cut;

the lateral cut is shorter here than the others, it is about 14 or 15 chains or 350 yards, the lift is 7 ft. 6 in. the dimensions are the same as the others, the length of the weir is 350 feet, the height from the bed of the river is about 11 ft. 6 in., the width of the river is from 100 to 130 feet. This takes us up to Red Stone Rock, and Cloth House, and to Stourport; the weir is to be in the cut there and the lock in the river, because the towing path is on the eastern side of the river, and we should have to pass over if we put a lock in the cut; I can't give the height of this weir. We dredge between Gloucester and Upton, because the shoals fall so much less in this district and are of a different character; they are shoals of deposit formed by the inequality of the sectional area of the channel. The shoals above Upton are hard beds of gravel and marl, which pen the water over in the summer season. The effect of dredging from Upton to Worcester would be to increase the liability of the banks to tumble in, and would also be inconvenient to the trader from the increased height of the banks, which are already too high: the same effect would be produced in a greater degree by dredging Upton shoal, unless there was something above. Compared with the present plan, dredging would be much more expensive, supposing it formed part of a continuous plan up to Stourport. If you removed the lock from Upton and put it at Diglis, you must have a double lift there, which would be inconvenient to the trade, as in point of fact it would be two locks. The extent of dredging in such a case must be to the extent of from 7 to 10 feet, which would be a serious matter, and would make cataracts from the locks. By the system of weirs we shall have 6 feet of water at all times from Stourport to Gloucester, which I believe would be sufficient for all purposes of trade on the Severn; I do not think it would be more than necessary for the canal boats. The build of vessels would alter if the water were deeper. In my opinion the trade of the river will be increased if these improvements are carried into effect. In my opinion if the maximum toll is imposed, these advantages will counterbalance it to the trade; I found that opinion upon the excessive delays, cost of lightering, pilferage, wear and tear, the increased power required to draw vessels up, the limited number of voyages and the light cargoes, which exist at present. The trade of Gloucester has suffered much in consequence, and has gone to other ports; to my knowledge many cargoes which, but for this, would have gone to Gloucester, have gone to Liverpool; this has been especially the case lately. I believe also that railways have increased the prejudice to the Severn. The cost of these improvements I estimate at £150,000, which will be sufficient, and more than suffice, and include contingencies, which I have estimated at 10 per cent. I am prepared to state in detail how it will be expended.

Cross-examined by Mr. Austin.

The original plan was made by Mr. Rhodes. I have been acting under Mr. Cubitt since Nov. 1825. I consider the merit or demerit of the present plan belongs to him. Mr. Cubitt was employed as consulting engineer, and Mr. Rhodes as acting engineer. I was employed by the committee of the late Severn Navigation Company. This is not the same plan as theirs, but the same with some alterations. Their plan was first made in 1838. There was a plan and sections. The original plan is at the Guildhall at Worcester. I have a reduced copy of it as altered. I took part in the formation of the original plan. It was adopted and altered by Mr. Cubitt. I said the deposit of shoals would depend on the drifts of the river. The river is divided in the plan into districts. The area of the first is at Upton, 3480 feet. That supposes a line drawn at the top of the bank and the bed of the river. The width is 104 feet, the average depth 11 feet. The next district is half a mile lower down, and has the same area; width 101 feet, average depth 10 ft. 6 in. The third is, area 3126 ft. width 98 ft. depth 11 ft. The fourth is, area 3401 ft. width 104 ft. depth 10 ft. 9 in. The fifth is, area 3529 ft. width 107 ft. depth 12 ft. The first section is half a mile below the Barley House, the second a mile ditto, the third a mile and half ditto, the fourth two miles ditto, and the fifth two miles and half ditto. That gives an average of 100 feet width and 10 feet depth, which is plenty of water for the necessities of the trade. There are no shoals there. When the water rises it expands also. The fall from Upton to Gloucester is about 7 inches, or 2·8 inches per mile. We propose to alter the whole river from Upton to Gloucester, to assimilate it at this part, and to maintain an uniform depth of 6 feet. The width of the river varies from 150 feet to 170 feet. I am not now prepared to give the Committee the detail of the cost of the works. Mr. Provis made the original calculation of the expense. The average dredging of the whole line will be less than 5 feet. The general estimate of the present plan was made by Mr. Cubitt at Worcester, in the autumn of last year. We had not a detailed estimate until within the last two months. I do not know that it is determined to lay down a quantity of rubble stone to be used between Upton and Gloucester. The depth of the water at the Upton weir immediately above is 7 feet, and below, 3 ft. 7 in. We propose to use the stuff dredged up in equalising the width. Mr. Provis took the price of the stone from me. It was from 3s. to 3s. 6d. per yard, delivered not at the spot, but on the Severn. Part of it comes from between Worcester and Stourport, and the other part from Malvern. I can't tell the cost of the stone and timber between Worcester and Upton. We propose to coffer-dam at Bevere Island. The soundings for the shoals were under my direction. The borings were in many instances from 8 feet to 10 feet. Maisemore shoal was not bored, it being out of the direct line. We bored all the other shoals. We took 26 borings in the Worcester shoal.

By Mr. Serjeant Wrangham.—I do not know the quantity of work to be done for the purpose of improving the navigation. It will be a work of considerable amount to get a depth of five feet at Deerhurst shoal with a width of from forty to sixty feet. The dredge below Upton Lock will be on an average of from 4 to 5 feet for the same width for the length of a mile. I believe these excavations will not depress the level of water because they are shoals of deposit and not natural formations, and there is no fall from them. By dredging to Worcester you would be making the river a succession of rapids; if we deepened to a sufficient extent in low summer water we should get rid of the rapids, but we should lower the ponds above; it would do so even with the same sectional area. By narrowing the banks and increasing the depth the stream would flow faster; the shoals do not pen the water back except where it acts as a natural dam. From Diglis lock to Upton weir the total depth is 4 ft. 6 in.; this space contains a great number of rapids; the fall is 4½ inches per mile, with a soft bottom, but with a shoal of hard gravel and marl. I think that dredging up to Upton would not retain the level; there would be a diminution at Diglis lock of 3 ft. 9 in. by dredging, if the water was not penned back by our lock; that would leave a fall of 9 inches from Diglis lock to Upton. The river is not so broad from Diglis to Upton as below Upton; and being so, the fall above is greater than the fall below, but it must not be naturally so; it depends upon the inclination of the bed of the river, and the quantity of water carried. Many rivers, particularly the Thames and the Kennett, have had their navigation improved by artificial means. The current of the Thames is much faster than in the Severn. The velocity of the flood of the Severn is from 2½ to 3 miles per hour. Mr. Provis can give you a more satisfactory answer than I, as to the force with which that would strike our weirs. I have seen a portion of the surface of the weirs in the Thames washed off by the water. They are made in a very simple way—by piles, filled up. Our weirs will be much stronger than the Thames. During the six years I have been engaged on the Severn my attention has been particularly directed to these subjects, and the information I have given to the committee is the result of that investigation. Mr. Provis was called in about two months since. I have made a calculation of the time at which the river may become free again; and taking all things into consideration, I think it may become a free river again in forty years, with the exception simply of a toll for keeping the works in repair. My estimate applies itself to the cost of tonnage. I am sure I furnished Mr. Cubitt and Mr. Provis with sufficient information to give an opinion on the subject. The time now lost in consequence of the shoals is much greater than will be lost in going through the locks. The impediments to the navigation of the river now are much greater than can possibly exist under the improvements. I have passed vessels through the locks on the Thames in 3½ minutes; about 5 minutes is a fair average. Supposing a boat to start to Gloucester in a fresh, which, before the alteration, could get back in the same fresh, it would have greater facility for doing so in consequence of the improvement of the river, notwithstanding the locks.

Mr. Provis, Engineer, examined by Mr. Serjeant Merewether:—I have executed works for Mr. Cubitt, and other engineers. The Menai Bridge was one of those works. The Birmingham Junction Canal was another, and I am now employed on works to the amount of £60,000 or £70,000. I was called in to give an estimate for the proposed works on the Severn, and Mr. Williams and I went down the river from Gloucester to Stourport, and I made my own observations in addition to the information given me by Mr. Williams. I have an estimate of the whole cost of the works, including 10 per cent. upon the cost of the works for contingencies, but exclusive of the land to be taken, which I do not pretend to value. The amount of that estimate is £133,108 12s. 3d., being £121,007 16s. 7d. for the total cost of the works, and £12,100 15s. 7d. for contingencies. I have made such a calculation that, if the work were offered to me, I should have no objection to undertake it at that contract, providing the supervision was such as I liked. Were I employed as an engineer to examine that estimate, I should say that it is a fair sum to give to any man to do the required work. The cutting required at Upton will cost £4656 17s. 6d.; the lock at Upton (including the building, the gates, and every thing necessary to complete it,) £6321 4s. 2d.; the weir at Upton, (including all that is necessary, rubble stone, &c.) £3887. [It was here understood that the odd shillings and pence should be left out to simplify the statement.] This would make the total expense at Upton £14,865. Worcester: cutting £4210, lock £6231, weir £2848; total £13,379. Bevere: cutting £1082, lock and coffer-dam (which I think will be required there) £10,768, weir £1569; total £13,421. Holt Fleet: cutting £3347, lock £5863, weir £1658; total £10,869. Lincombe Hill: cutting £5126, locks and dams (not coffer-dams but embankments) £8072, weir £2016; total £15,214. Total of the five totals £67,750. The five lock-houses will cost £1250. This includes all the work except the equalisation and works below Upton. The total dredging will cost £18,141. Protecting the sides of the river, £33,866. These two items make £52,007. The three totals make £121,000. With the best judgment I can form, I think this is sufficient for the work. I have made estimates to the amount of millions.

Cross-examined by Mr. Austin.—The quantity to be dredged between Upton and Gloucester, including both branches of the river, is 311,000 yards, which I estimate at 1s. per yard. I believe that to be the full price, and I include the taking away and depositing the soil, the whole of which is proposed to be used in narrowing the river. There is no intention to take any away, except, perhaps, throwing a little into some of the deep holes, and putting some of the best gravel on the towing paths, which are very bad. This work, will come to £15,500, which is a very large proportion of the total cost of dredging, leaving only £3000 more to be expended on dredging between Upton and Stourport. It is proposed to face the channel with rubble stone, at an inclination of 3 to 1, extending from the bottom of the dredged channel to the height marked in the section to represent the spring-tide level. There will be 193,520 square yards of rubble stone facing between Upton and Gloucester, or about 132,000 cubic yards, at 3s. 6d. per square yard, or 5s. 3d. per cubic yard. The stone can be procured at the Red Stone Rock, at Lincombe Hill, and at Holt Fleet. The mode in which the facing is to be done, is first to set the dredging machine at work, and then to throw the stone promiscuously into the channel, marks being set up for the guidance of the men who discharge the cargoes of stone. The rubble stone facing was my suggestion, and Mr. Cubitt has adopted it. I cannot tell how much sand or how much gravel will have to be dredged above Upton, as the quantity of dredging is so very small that I did not consider it worth while to examine very minutely. It would be a little harder to dredge stones than gravel, but not much, because if the stones were large we should remove the buckets from the machine and replace them with claws, which would take up detached stones. I estimate the excavation at 10d. per yard, which includes the removal of the soil, placing it behind the stone walls, and sloping it from the top. We shall be driven to the plan of dropping in the stones for [illegible] surface, when they will be placed by hand, excep[illegible] then all the stones will be laid by hand. At the foot of the weirs it is proposed to have rubble stone, sloping at an angle of 3 to 1. We propose to make our weirs water-tight by having the sheet-piling jointed and grooved, and, as it will be driven comparatively dry, the swelling of the wood when it comes in contact with the water will be quite enough to make every joint water-tight. We do not resort to puddling. I have not made any estimate of the cost of the land which will be taken, nor for any compensation in case the drainage is affected. I have only estimated the cost of facing one side of the river at any place. This estimate has been in progress two months. I have not made any alteration in it from the first, saving to correct some little [m]istake respecting the quantities.

Re-examined by Serjeant Merewether.—The reason why I use stone instead of dwarf piling is because it is more durable than timber, and more proper to be used; but if it became a question, and it was deemed desirable to use timber in any particular part, then I should adopt timber. There are localities near the river where we can get stone very easily. The price I have stated is quite sufficient to cover any difference in the nature of the soil to be dredged. In constructing a weir we first put in piling. I have no reason to apprehend that the stone will be carried away, because there will be a great mass of it, placed at a considerable slope; I think the weirs will be quite strong enough to resist all pressure. I have not made any of these weirs myself, but I have taken drawings of some which have well answered the purpose for which they were designed. The walls are of the same description as those adopted by me in the river Dee, which is a rapid river. My cross-examination does not shake my conviction in the least, as to the strength of the wall.

Mr. Cubitt examined by Mr. Serjeant Merewether. The following are the principal items of his evidence:—Our plan will not affect the drainage below Upton at all, and will be the best with reference to expense. The dredging at Maisemore will be so small that the effect of it upon the Gloucester channel will be inappreciable. We shall dredge in the deep water channel. The plan [illegible]ed above Worcester has been adopted because in that district our object can be better and cheaper attained by it and with less injury to the surrounding lands. As an explanation of this, six inches of water going over a weir 600 feet long would take all the summer water in the Severn; 25 inches over a weir so constructed would make a good navigation and effect a good drainage of the land, and before injury could ensue the weir would become obsolete. We seek a channel of 45 feet from Upton to Diglis, with a rise at three inches per mile. The amount of dredging here would be upwards of 300,000 cubic yards, at 1s. per yard, which would be £15,000, which is the price of all the works at Upton. The lift between Worcester and Upton Bridge must be the sum of two lifts. If the two falls be brought to Worcester there must be two locks at the double fall, which would be more expense, in addition to the cost of £15,000 for dredging. I therefore think this is a sufficient reason why the weirs and locks should begin at Worcester. I apprehend there will be no difficulty whatever in the works answering their purpose when made. In putting the weirs across the river quite square it becomes a dead stop in proportion to the height and width of the weir to a portion of the section of the river, and backs up the water; but the quantity of water that falls over the weir is never of a longer sheet than the breadth of the weir, so that were the banks full there must be an obstruction. An oblique weir is the simplest, cheapest, and most efficient to dam up the river without injury. [To elucidate this, Mr. Cubitt produced a model of the pro[posed] works and explained them in detail to the Committee, and also the scientific principles on which they were adopted.] I have considered the [illegible] the sluices in the weir. I think them inexpedient. The flood gates would have no perceptible effect in such a case; and flood gates, as such, in the weirs would cost more than the weirs themselves. The weir is quite as capable of penning off the water without flood gates as with them.—If any works are put to improve Lord Sandys' drain it would not impede the navi[gation]. My object has been to raise all the works, towing paths, &c., above [illegible] —I do not intend to dredge away the quantity Mr. Provis stated at Maisemore shoal, or to do more to it than will be necessary to let the Maisemore boat pass. There is more in the Parliamentary sections than is necessary to be done, and so far there is a greater degree of safety.—I was first employed to make observations on this river by Mr. Lea, the Chairman of the Association at Worcester. I made my report to Lord Hatherton, the Chairman of the Committee of the Severn Association. I had met Mr. Williams professionally before. I was engaged with Mr. Rhodes in the plan of 1836; that was a plan involving the erection of weirs above and below Gloucester; the weir below Gloucester would have been in a portion of the river now avoided by the Gloucester and Berkeley Canal. The plans of the present day are the same amended; I approved of them in general, but not in all things. I have no doubt that we might get six feet of water by dredging up to Worcester, but it would be much more expensive. It is proposed to place a wall where we dredge. I have estimated for eight miles of walling and dredging; that will answer the double purpose of narrowing the river and securing the [illegible]

[illegible] cross-examined by Mr. Wortley.—Mr. Williams correctly de[scribed the mo]de of laying down the rubble stone. At one time I proposed [illegible]ing in some places; and I still intend to do so, where I think it will be as cheap and efficient. In some respects it is preferable to stone, in others it is not so. I can't mention any part of the river in which I think it will be preferable. I do not propose to make the slopes of the banks perfect in all places, as Mr. Provis did, because I think there will not be stuff enough to do it. The channel of the Deerhurst shoal is rather straight; the deepest water is towards the left bank going down. It is not absolutely necessary to stone up to the high-water mark. The length of the dredging on the river between Upton and Gloucester upon my scheme, as marked on the sections, is between eight and nine miles. I should remark, that it is marked deeper than will be necessary for the navigation. I do not [illegible] works below the Gloucester and Berkeley Canal, nor below [illegible] the Gloucester and Hereford Canal. The continuous length o[f] [illegible] the sections, from Upton to Diglis is [illegible]. We propose to start from Upton at a depth of 7 ft. 8 in.; and we do so because I don't think 6 feet sufficient. By the 6 feet spoken of as the depth we seek, I mean 6 feet above the lock sills. I save all the dredging there by penning the banks. Were we to dredge from Gloucester to Worcester to a width of 45 feet at the bottom, to the level of the lock sill of the Gloucester and Berkeley Canal, 3 feet in depth, with a slope of two to one, and rising 3 inches per mile, the quantity to be dredged would be 328,183 cubic yards. [Witness then answered a series of [illegible] the volume of water that would flow in channels of different widths.] We shall scarcely affect the fall below Upton. We propose at [illegible] to form a close jointed waterproof weir, slanting, 600 feet long, with pilings drawn into the river, 10 feet apart; behind this we propose to drop stones into the river, without masonry. The expense of having the lock at Diglis, instead of Upton, would be very much increased on account of the additional fall. In some places where we construct our weirs we widen the river, in which cases the cross sections would be as great or greater than at present. I measured that section across the river at right angles to the stream. The height of the water above the weir is 6 inches. I know by principle, and partly by practice, that when the water is 2 feet above the weir the boats will go over. The water, in coming to the weir, does not diminish its velocity, and no more water would pass over the weir in consequence of its being oblique than if it were right angled. I do not make a pond, and therefore I do not cause a deposit. If you do any thing to diminish the velocity of the water coming through the weir it will tend to form a deposit; but if it be so constructed that the water coming through can keep moving on with the same velocity, it will have no more tendency to form a deposit than before the weir was put in. If I were to carry out the works at once I do not intend to make any alteration in the length of the weir; and if I did so at all, it would be to meet the views of others rather than my own convictions. If the river be increased beyond its natural width it will be more liable to deposits. The expenses of general maintenance of the works can never cease while the works exist. The expense of the navigation of the Ayr and Caldwell is very considerable. We do not alter the natural surface of the water at Diglis locks to any extent; if the weir were placed above the entrance to the canal, vessels would have the same depth of water. The reason I have for not placing it higher up the stream is that it would lengthen the cut very much, take more land, and much reduce the water to what I may call the harbour of Worcester. The length to the harbour is 1000 yards; it would increase the length of the cut about nine chains. There would be great passing of vessels from all places at the point, and therefore I think there should be a good harbour. If the vessels coming at the same time had to wait for the lockage, it would be the best place to wait in, but there would be little or no waiting, as they would pass the lock in three or four minutes. At Bevere Island I propose to put the weir below the mouth of the Salwarp; Mr. Rhodes in his last plan has placed it in the same place. By putting a weir in a shallow stream we raise the water; but the instant it gets so much above the weir as to lose a fall, from that instant the weir is no obstruction. I have had but little experience in salmon rivers; I understand there are good salmon in the Severn, and I should be very sorry to do anything to destroy them; I have nothing to do with how far these works will affect the rights of piscary; I have considered how to form the weirs so as not to obstruct the salmon in passing up the river; the weirs will not afford any facility for taking the fish. The average yield of the river at low summer water is from 40 to 60,000 cubic feet per minute above the Avon; the quantity of course differs below the Avon.

By Mr. Lowndes.—I have not personally taken the levels of the drains on the river Severn; I received information from Mr. Williams, and a great deal from Mr. Rhodes; I don't know that Mr. Rhodes personally took the levels. I received the greatest information on this point from the documents. I examined the drain on Lord Sandys' property myself; if you proved there was an under-drain there it would not matter on atom. I consider the sole operation of a drain to be to take the water off the surface of the land; the effect of an under-drain is to take off that which gets below the surface of the land. If there is an under-ground drain it does not follow that the level must be the same as that of the open drain. I do not know whether there is an under-ground drain at this place, but I believe all the drains on Lord Sandys' property come into the Severn below the weir.—When a fresh comes down the river the surface of the river will remain nearly the same as before the weir was put in. The works will raise the water on the river at Salwarp perhaps four feet. The value of the land to be taken will be proved hereafter by other witnesses. If it should be proved that 2000 acres for instance would be injured in their drainage by the bill, there has been no estimate made of the amount of compensation for that. I can't give any opinion as to the permanency of any damage that might ensue. I admit that the consequences of imperfect drainage would be to effect the atmosphere of the district. The state of the towing paths is not good; they give way on both sides of the river. When they have given way, it is generally the case that the land is encroached upon for a fresh one, which they are entitled to do. If they are entitled by their Act to take 10 feet on the side of the river, and that falls in, I am of opinion they can take 10 feet more; notwithstanding this, I do not think it is imprudent in us to undertake their management.

Mr. Mc'Neil examined by Mr. Serjeant Merewether.—I am a civil engineer, and have been engaged in many extensive works for a period of 20 years. I have been present during the last few days of this enquiry. I have been en[ga]ged in works of a similar description to the present. Having heard the plan, I think it would effect the desired object. I think it would be best [to] dredge up to Upton. I think, also, that the weirs will effect Mr. Cubitt's object. With reference to expense, I think it is [illegible] [illegible] adopted. I think the explanation given by [illegible] [illegible] [illegible] to be added to it.

[illegible] by Mr. Austin.—I was called in on this [illegible] I had not made a previous examination of the [illegible] [illegible] I have been across it at Upton, but [illegible] it. I do not know any other river of a similar [illegible]

[illegible] opinion on the effect of the weirs. I do not give any opinion of the proper mode of dealing with the peculiarities of the river Severn. I form my opinion on general scientific principles—that the effects described by Mr. Cubitt will take place. I am now constructing sea walls where there will be a weir, but I have never constructed one across a river. The present weirs are of great length. I have heard of the mode in which it is proposed to construct them. I see no use for a foot frame in the present case. I think it will stand, as the stones are to be dropped in. I do not think the water will have any effect upon the stone so deposited. The pressure is removed to a great extent by the sheet piling. The water will go over the top of the sheet piling, and find its way through the stone works. It will perforate in a gentle manner, and not disturb the stone work. In flood there will be no fall at all, because it will be the same height above as below. I don't think I ever saw a large weir of this kind; I have seen small ones in canals, and I can apply the effect produced in other places to the present case. Many weirs in this country and others are formed simply by loose rubble stone. The finest I ever saw, which is on the Boyne, is so constructed. A weir of this description is made water-tight by the sheet piling above it. If it should slip I should pack it again with fresh stone; it would be little expense. I am getting packing done now at 6*d.* per yard for labour. The former stone would be available. I am aware of the object of putting the weirs across the river; it is for the purpose of getting a higher level above. It is placed obliquely, to afford greater facility for the passage of flood water. I am of opinion that it would. I have myself proposed it. It is now being done in the river Shannon. I am not engaged there, but I have made many experiments on the subject. When the weir is placed right across the river it diminishes the water way by the whole superficial area of the weir. It is the same when it is placed obliquely, until the water flows over. As soon as the water rises over the weir the circumstances are altered, and there would be less obstruction, in proportion to the length of the weir, when it is placed at right angles. The summer water would be at the same level, above and below, in either case. In time of floods the water comes down at all points of the weir at equal depth. It would always do so with an oblique, but not with a right angled one. I don't see any reason why, in an oblique weir, the water should make to the lower angle; it would pass down parallel with the axis of the river, or to the banks, if the banks are parallel. That is my deliberate opinion. This principle may be applied in all cases of flood. The water will not fall in the same manner, but will take the shortest line. If the water is rapid it will form an acute angle at the crown of the weir. I don't think water a foot deep will fall in this way. If you want to double the capacity of the weir you should more than double its length. If you did so with a weir directly across, you must widen the river.

Mr. Cubitt explained, that wherever he proposed to put a weir, if the river was not wider at that part than above and below, he proposed to widen the river at that part for the whole extent of the weir, to an extent at least equal to the cross section of the weir; the consequence of which would be, if they took the cross sections, the channel would amount to the sectional area, at least, to the section of the river above and below.

Mr. Mc'Neil's examination, resumed.—I have made experiments as to carrying a double quantity of water over a weir. I simply speak of the quantity passing over, not of its approach. Not knowing the river, I can say nothing about the dredging.

By Serjeant Wrangham.—I do not know how much it is intended by the Upton weir to pen up the water at the tail of the weir above. Whatever height of water is penned back above the present summer level at half a mile above Upton weir, will be so much abstracted from the water-way of the river. When the current passes over the weir, it will pass at a higher level than before the weir was there, by very nearly the depth of the water penned back by it, added to the depth of the column of water passing over the weir. In cases of flood the section of water-way for carrying off the flood will not be diminished to the extent of the water penned back, because the dam below is at the same time increasing in height, until it comes to the same level, when the weir becomes no weir at all. Supposing the water to be penned back within a few feet of the top of the bank, the river above being contracted, all the water that can pass will pass over the weir.

Re-examined by Mr. Serjeant Merewether.—The question just put to me relates solely to the capacity to retain, and not to obstructions and the facilities of avoiding them. The discharge of water over the weir will be in proportion to the length of the weir. I have heard of this principle for seven or eight years. The construction of the Breakwater in the Plymouth Sounds is the same as it is proposed to construct these weirs. I consider it to be the best mode of constructing weirs.—I have been professionally employed on many rivers. The weir on the Boyne stands very well. If the force of a river be five miles per hour, it would strike a weir directly across at the same force, but if the weir is oblique, the force which strikes against it is represented by a line drawn at right angles, and if the hypothenuse is five, the force that would strike that side would be nearly three. If a weir pens up five feet of water for a mile the water becomes stagnant, while it fills up to the weir; but if a fresh should come it would not produce any impediment to its passing over an oblique weir.

(To be continued.)

MISCELLANEA.

Daguerreotype Portraits.—A new discovery was communicated at the last sittings of both the Royal Society of London and the Institute of France in Paris, which is one of the most important improvements made in the Daguerreotype process, particularly when applied to the art of taking portraits. Mr. A. Claudet is the inventor of this discovery, which consists in the combination of chlorine, with the usual preparation. It is sufficient to expose the plate for one or two seconds to the vapours of that gas, to render it so sensitive to the effect of light, that the time of exposure in the camera obscura is shortened from 4 or 5 minutes to 10 or 15 seconds. This result must be of the greatest importance in taking likenesses, as the great difficulty in getting a person to sit immoveable for so long a period as was formerly required, always acted as a serious obstacle. Mr. A. Claudet is entitled to the warmest acknowledgments for his invaluable discovery, and for having been liberal enough to communicate it to the public. We understand that the inventor is carrying on his process at the Adelaide Gallery, and that his likenesses are exquisitely executed.

The Princess Royal Steam Pleasure Boat.—On Wednesday June 9th, this newly-built pleasure boat, propelled by the Archimedes screw, made her first pleasure trip from Brighton to Arundel and back. She was very recently built on the Tyne (under the direction of Messrs. Bass, W. Catt, jun., and Collins, the committee of the owners) from which port she arrived on the 8th June, in the short space of 48½ hours, the distance being upwards of 400 miles. She is of the following dimensions: length of keel 81 feet, breadth of beam 17½ feet, depth of hold 10 feet, of immersion 6½ feet, tonnage 101 tons register. There are two engines each of 23 horse power, the screw is 5 feet diameter, 6 feet pitch, and 34 strokes of the engine making 170 evolutions is the regulated speed. The velocity of the boat is about 8 knots an hour (equal to about 9½ miles.)

Horsham.—The new church of St. Mark's (the first stone of which was laid in April 1840), was consecrated on the 3rd instant. It is in the early English style. The new school-room adjacent is also completed. Now the work is finished it is due to the architect, Mr. Mosely, and the builder, Mr. Darby, to say that both design and execution are highly creditable. Still, the continuation of the parapets the whole length of the building, and the adoption of stone in lieu of slate for the roof would have been decided improvements. Doubtless the *funds* influenced these matters. The church contains 900 sittings, and the cost, including gas fittings, boundary wall, and a few other extras, is less than £3500. It must, however, be stated that the ground was a gift, as was also the use of a stone quarry.

Faculty of Engineering in the University of Dublin.—The authorities of Dublin University seem to be anxious to aid in the present movement for extending instruction in the practical sciences, and have given notice of their intention to form a faculty of engineering in Trinity College. The faculties now are London, Durham, Glasgow and Dublin, and the schools Woolwich, Chatham, Sandhurst, Addiscombe, King's College, University College, Museum of Economic Geology, Putney, Durham College, Edinburgh Academy, Glasgow College, Dublin College, and the Mining School of the Royal Dublin Society.

Société des Architectes.—A Society of Architects is in progress of formation at Paris, on the model of the Institute here, which we hope it will worthily emulate.

Powers of Locomotive Steam.—A steam coach running at a moderate rate, which is about 21 miles per hour, would run over a distance of 500 miles per day of 24 hours, and at that speed would reach British India from London in about 8½ days—or Pekin in China in 11 days—or from Gibraltar to the Cape of Good Hope in 10 days—or from Quebec to Cape Horn in 17 days—or once round the globe in 51 days—or 7 times round the globe in one year—or a distance equal from the earth to the moon in about 16 months, or from the earth to the sun in 500 years.—*Greenock paper.*

Pompeii.—A search among the ruins of Pompeii, which took place lately, led to the discovery of a marble statue, a silver vase, and a quantity of gold, silver, and bronze medals, in a good state of preservation.

Locomotive for Common Roads.—A gentleman residing at Southwell, Dr. Calvert, has constructed a machine, which he purposes to call "The *Alternate*," because he rides or walks in turn according to the ascending or descending inclination of the road he travels. By merely rising from his seat, and throwing part of the weight of the body upon the hands placed on a guiding bar, he *walks* with less fatigue than he could do without the machine, especially where the ascent is not very steep. On descending he sits down and *rides* at his ease with considerable speed. The propelling action (the most powerful that can be exerted, and one of the most lasting is that of rowing. *Nottingham Journal.*

Paper from Asparagus.—We have pleasure in hearing that one of the most famous paper manufacturers, M. Diercks, of Ghent, has collected all the stalks of asparagus that come from the tables d'hôte and great houses of the town, in order to convert them into paper. Every evening two or three loads of these fibrous stalks are carried to the rolling mill, and thence to the stamping machine, which triturates them in the course of a few hours. The kind of paste which is thus produced does not require bleaching. It is put into a tub, and taken to the paper-making machine, from which it issues converted into excellent white paper, the expense of which is not half that of paper made from rags. We have no doubt that when this secret is once known, it will be eagerly appropriated by all large manufacturers. Asparagus mixed with the pulp of beet-root produces a kind of paper, which is even superior. —*La Fanal.*

A Steam Organ.—M. Lax, jun., has just invented a steam organ, which can be heard through the extent of a whole province. This instrument, consisting of vibrating plates of metal, is so regulated that it is acted on by steam of four or five atmospheres of pressure. These plates are merely very large steel bars, which can only be made to vibrate by very high pressure steam. This monster organ is fitted for popular solemnities and inaugurations of railroads. It may be placed upon a wagon in front of the engine, which will supply it with the same steam that moves the piston in the cylinders. The sound of this stupendous instrument would overpower the noise of the issuing steam, the working of the wheels, and the roaring of thunder.—*Le Fanal.*

of the rope manufactory at Boston. "The ropewalk of the navy-yard is one of the finest I ever remember to have seen. It is nearly half a mile in length, two stories in height; it is built entirely of the same beautiful granite as that used in the construction of the dry dock, and is roofed with iron and slate. The window shutters are all cased with iron, and the whole is rendered fire-proof. Some very recent and excellent improvements have been introduced into the machinery here, by a native American engineer, Mr. Treadwell, by which a steam engine at one end of the building is made to furnish the requisite power for performing all the operations for rope-making, with very little aid from the labour of men, from the first combing of the hemp, and spinning it into threads, to the tarring and twisting the yarn, and the winding of the whole into the hawser or the cable required. I had seen some of the best ropewalks in England, both in the royal dock-yards, and in the private establishments of London, and other parts, but I remember nothing equal to this of Boston, either in the beauty and perfection of the building and the machinery, or the admirable uniformity of strain in every strand and every fibre in the rope produced; or the finished roundness, smoothness and flexibility of the hawsers and cables, of which several were submitted to our examination, both in progress and completed."

Steam Navigation on the Meuse.—One of the new steam-boats intended for the Liegeian Company of Navigation, was last week launched in the Meuse. It was towed as far as the railway to Val-Benoit, in order to put in the boiler. Without the boiler, and with the engine alone, the draught of water of the boat was 21 centimetres (8 inches); with the boiler it is 25 centimetres (10 inches). The engine, which is a low-pressure one, and according to the Jackson plan, weighs only 2,400 kilogrammes. It was constructed in the manufactory of Messrs. Derosne, Cail, and Co., at Charenton, near Paris. Excepting in England and on the Loire, there are not yet any engines like it. The engines of the steam-boats which were in operation last year on the Meuse, were considerably heavier. The vessel which has just been launched is 3 metres and 50 centimetres (11 feet) in depth, and 36 metres and 50 centimetres (118 feet) long. Every thing on deck is nearly finished, and it will soon be able to commence working. Great progress is made in the construction of the second vessel, and it will be ready for service in a short time after the first. It is estimated that the draught of these boats, with their load of fuel, will not exceed 35 centimetres (14 inches), while that of the former boats amounted to nearly 60 centimetres (24 inches); we are, therefore, induced to hope that steam navigation, unless when the waters are excessively low, may henceforth be generally adopted on the Meuse.—Another steam-boat of iron is now constructing in the manufactory of M. Petry, an engineer, at Grevegnée-les-Liége. Persons experienced in the art of boat-building, who have had opportunities of seeing this fine vessel, consider that the country has not produced any equal to it.

LIST OF NEW PATENTS.

GRANTED IN ENGLAND FROM 27TH MAY, TO 25TH JUNE, 1841.

Six Months allowed for Enrolment.

[illegible] BENT OLLIVANT and ADAM HOWARD, of Manchester, mill-[illegible], for "*certain improvements in cylindrical printing machinery for printing calicoes and other fabrics, and in the apparatus connected therewith, which is also applicable to other useful purposes.*"—Sealed June 5.

[illegible] MEE, of Leicester, framesmith, for "*improvements in the manufac-[illegible] fabrics.*"—June 5.

[illegible] HANNIS TAYLOR, of Lambeth, Esq., for "*certain improvements* [illegible]"

JOSEPH GIBBS, of the Oval, Kennington, civil engineer, for "*certain improvements in roads and railways, and in the means of propelling carriages* [illegible]."—June 5.

MILES BERRY, of Chancery-lane, patent agent, for "*certain improvements in machinery or apparatus for ruling paper.*" (A communication.—June 5.

JAMES COLLEY MARCH, of Barnstaple, surgeon, for "*certain improved means of producing heat from the combustion of certain kinds of fuel.*"—June 8.

HENRY RICHARDSON FANSHAW, the younger, of Hatfield-street, Surrey, [illegible]mist, for "*improvements in curing hides and skins, and in tanning, washing, and cleaning hides, skins, and other matters.*"—June 10.

JOHN GEORGE BODMER, of Manchester, engineer, for "*certain improvements in machinery for propelling vessels on water, parts of which improvements apply also to steam engines to be employed on land.*"—June 10.

[illegible] EDWARD HAMMOND B[illegible], of Heybridge, Essex, [illegible]"—June 10.

[illegible] WAITE, of the "Morning Advertiser" office, Fleet-street, [illegible] "*certain improvements in machinery or apparatus for letter-press printing.*"—June 12.

JOHN ANTHONY TIELENS, of Fenchurch-street, merchant, for "*improvements in machinery or apparatus for knitting.*" (A [illegible])—June 12.

[illegible] for "*im-*

[illegible] ALEXANDER HORATIO SIMPSON, of New Palace-yard, Westminster, gentleman, PETER HUNTER IRVIN, and THOMAS EDWARD IRVIN, both of Charles-street, Hatton-garden, philosophical instrument makers, for "*an improved mode of producing light, and of manufacturing apparatus for fusion of light.*"—June 17.

THOMAS WALKER, of North Shields, engineer, for "*improvements in steam* [illegible]."—June 18.

[illegible] PETRIE, of Croydon, gentleman, for "*improvements in obtaining mechanical power, which are also applicable for obtaining rapid motion.*"—June 19.

JOHN HAUGHTON, of Liverpool, clerk, master of arts, for "[illegible] *in the method of affixing certain labels.*"—June 19.

JAMES HENRY SHAW, of Charlotte-street, Blackfriars, jeweller, for "*improvements in setting wheat and other seeds.*"—June 19.

SIR SAMUEL BROWN, knight, of Netherbyers-house, Ayton, Berwick, for "*improvements in the means of drawing or moving carriages and other machines along inclined planes, railways, and other roads, and for drawing or propelling vessels in canals, rivers, and other navigable waters.*"—June 19.

JOHN GEORGE TRUSCOTT CAMPBELL, of Lambeth-hill, Upper Thames-street, grocer, for "*improvements in propelling vessels.*"—June 19.

JOSEPH GAUCI, of North-crescent, Bedford-square, artist, and ALEXANDER BAIN, of Wigmore-street, Cavendish-square, mechanist, for "*improvements in inkstands and inkholders.*"—June 21.

MILES BERRY, of Chancery-lane, patent agent, for "*a new or improved engine, machine, or apparatus for producing or obtaining motive power by means of gases or vapours produced by combustion.*"—June 23.

WILLIAM WALKER, the elder, of Standish-street, Liverpool, watch-finisher, for "*an improvement or improvements in the manufacture of the detached lever watch.*"—June 23.

GEORGE THOMAS DAY, of Upper Belgrave-place, Pimlico, gentleman, for "*an improved apparatus for creating draft applicable to chimneys and other purposes.*"—June 23.

JOHN HENRY LE KEUX, of Southampton-street, Pentonville, for "*an improvement in line engraving, and in producing impressions therefrom.*"—June 23; two months.

JOHN GOODWIN, of Cumberland-street, Hackney-road, piano-forte maker, for "*an improved construction of piano-fortes of certain descriptions.*"—June 23; two months.

JAMES SIDEBOTTOM, of Waterside, Derby, manufacturer, for "*certain improvements in machinery for apparatus.*"—June 23.

WILLIAM CHESTERMAN, of Burford, Oxford, gentleman, for [illegible] *ments in filtering liquids.*"—June 23.

ROBERT STEPHENSON, of Great George-street, Westminster, civil engineer, for "*certain improvements in the arrangement and combination of the parts of steam engines of the sort commonly called locomotive engines.*"—June 23.

JOHN LEE STEVENS, of King Edward-street, Southwark, general agent, and JOHN KING, of College Hill, printer, for "*certain improvements in candle-sticks and other candle holders.*"—June 25.

TO CORRESPONDENTS.

Mr. Mushet's papers; and Mr. Davies and Mr. Ryder's reply to Mr. [illegible] *answer, that appeared in last month's Journal, were not received until the latter part of the month, they will appear in the next Journal.*

M. Q.'s communication will appear next month—tracings will be returned when required.

"The Mammoth" is to be worked by the Screw, unless new orders have been lately given to the contrary.

[illegible] *must beg of our American correspondents not to forward Pamphlets* [illegible] *we have had several demands upon us for 5s. and 6s. postage for each.*

A lengthened abstract of Mr. Hood's excellent paper "on the Properties and Chemical Constitution of Coal," has already been given in the Journal, and the paper besides has appeared in another periodical.

Works received and will be noticed next month—Mr. Rankin's Patent Wood Pavement, Report on "the Improvement of the Navigation of the Forth Stirling and Alloa," "Irish Railways," Mr. Sopwith's description of Geological Models, and Mr. Williams's work on the Combustion of Coal, 2nd edition.

Communications are requested to be addressed to "The Editor of the Civil Engineer, and Architect's Journal," *No. 11, Parliament Street, Westminster.* [illegible] *sent early in the month, communications on or before the 20th (if with drawings, earlier), and advertisements on or before the 25th instant.*

Vols. I, II, and III, may be had, bound in cloth, price £1 each Volume.

ERRATA.

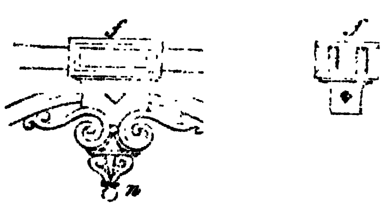
Scale of inches and feet for detail.

RAILWAY STATIONS.

The Revue Generale contains a description of several Railway Stations both in England and on the Continent, illustrated with details of their construction, from which we extract the following information relative to the Paris Station of the *Left Bank Versailles Railway*, situated near the barrier of Maine.

The terminus of the railway is on an embankment 23 feet high, which offers serious impediments to the construction of buildings, turn tables, and other works requiring solidity. The terminus consists of three ways with a platform on each side for the passengers on their arrival and departure. The whole of this was covered over with a semicircular roof of iron, which fell down soon after its construction, during a hurricane on the 16th of September last. The semicircular form without any stays forming direct angles is at all times a bad mode of constructing buildings, where they are subject to the powerful action of the wind, as its force impinging upon any part is transmitted through the whole, and when successive gusts of wind are continued, this transmission of the force becoming more and more formidable like a wave in a tempest, must in the end lead to the destruction of any building that is built of such slender materials as the one now before us. The roof possesses considerable ingenuity in its construction, for its lightness and elegance of its form, we shall therefore notwithstanding its failure, proceed to give some account of its construction.

Fig. 5.



The roof is of a simicircular form 161 feet long, and consists of 13 main ribs or arches placed 12 ft. 6 in. apart in the clear, 10 of which were 57 feet span, and three at the extreme end of the station 70 feet span. A section of the roof is represented in figs. 1 and 2, with four of the tangential curvilinear stays omitted. The main ribs spring from an upright cast iron base (fig. 2,) standing on the timber piles which carry the passengers promenade platforms, these piles are tied across the railway transversely at about 4 feet below the top of piles, or 3 feet below the surface of the rails by strong wrought iron ties, to prevent them spreading. The ribs are composed of 5 bars of wrought iron up to the top of the column, fig. 2, the two external bars ½ inch by inch, the two next ½ by 1½ inch, and the centre 1½ by 2 inches, all bolted together; above the column and up to about two-thirds the height they have only 4 bars, omitting the centre, and the remainder have only the 2 external bars. These ribs are strengthened by tangential curvilinear stays, consisting of wrought iron bars ¾ inch square placed diagonally and secured in the centre by the ornamental coupling *n*, fig. 5, and at each end by the pendant *x*, shown more in detail in fig. 6, and secured to the main rib. There are also similar tangential curvilinear stays springing from the same pendants at right angles to carry the purlin bars as shown in the lower part of fig. 3, for the support of the rafters and covering, the lower tangential stays abut upon the top of the wrought iron column 1½ inch diameter (fig. 2). The pendants (fig. 6,) consist of a cast iron baluster, the 2 bars of the main rib passing through the head (*a*), and also at right angles the purlin bar. The 4 ends of the tangential bars are secured in the holes at the 4 angles of the base *c*, which is hung up to the bars of the rib by a nut and screw bolt passing through the centre of the pendant; the d an *c'* shows the position of these holes, that in the centre receiving the bolt just described, and those at the 4 angles the tangential stays; the drop *e*, with the collar *d*, is fastened on to the top of the pendant and conceals the bolts, the bottom part of the baluster fits in with the conical shaped end (*b*) into the embrasure (*c*).

Fig. 6.

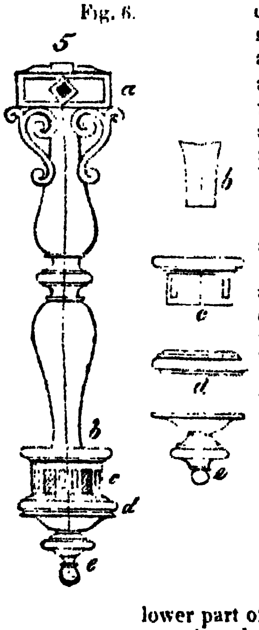


Fig. 7.

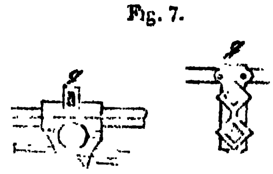
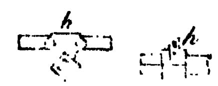


The purlin bar and the curvilinear stays were secured by the coupling *g*, fig. 7, and fig. 8 shows the coupling of the purlin and the rafter *h*, which were of wrought bars 3 by ¾ inch placed 18 inches apart, as shown in fig. 4. The covering was of galvanized sheet iron laid with a folded seam similar to zinc.

Fig. 8.



The upper part of the roof was covered entirely by a skylight, laid to an angle of 25°, the lower part was supported by the light ornamental iron work shown in fig. 3, supported by the tangential stay bars.

We here give the weights of the principal parts.

Base of the column	- - -	5 lb.
Capital	- - - - - -	9¼ lb.
Pendants of cast iron	- -	26 lb.
Great S shaped guard of the lantern	-	36¼ lb.
The parts *m*	- - - - -	10½ lb.
n	- - - - - -	7¾ lb.
o (cast iron)	- - -	7¼ lb.
p	- - - - - -	3¾ lb.
h	- - - - - -	¾ lb.

The total weight of the casting of the roof was 5 tons 6 cwt.

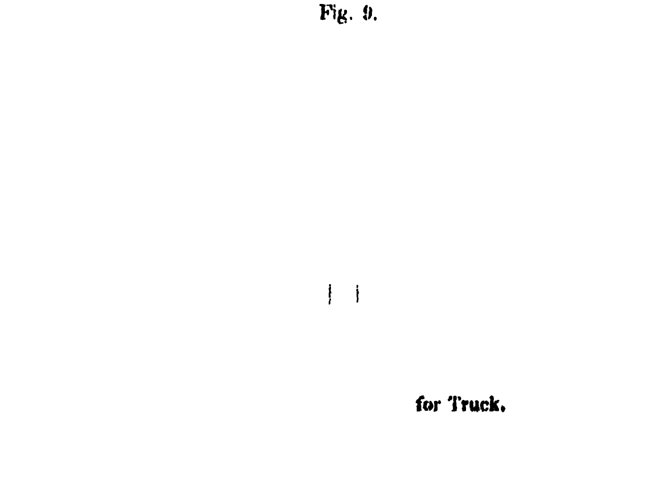
That of the other iron work 13 tons 5 cwt.

The total cost including painting and glazing was 25,000 francs, (1000*l*.), and as there were about 1000 square yards of surface, that gives 1*l*. per square yard covered, undoubtedly an exceedingly low price.

It will be seen from the preceding description what a great number of cast iron pendants and couplings compose this roofing, but at the same time that the different shapes are not numerous, and that the models are few. In wrought iron in order to obtain this variety of shape, it would have been requisite to have forged each piece separately, and to have had much manual labour. It will be further perceived that all the pieces are simply cut in lengths, without being reforged or filed. The iron on coming from the forge, is bent cold according to the form required, and then fixed in the cast iron pendants by means of bolts, so that it is not necessary to employ iron of superior quality that can be worked hot; it is only necessary that it should not be cold short. It is this arrangement to which we principally wish to call attention, as it is the reason which has induced us to publish the preceding description, as an instance of an iron roof easily put together and composed of a minimum weight of cast and wrought iron. It will be seen that such work can be made at a distance and then put up on the spot. It is only necessary to send the pendants and couplings, and the bars of rough iron, which are to form the roof, and which can be cut up on the spot, and bent according to circumstances. As the coupling pieces are of cast iron, ornaments can be introduced in the casting, and an elegant appearance given without much expense. With these advantages had M. Fauconnier designed it with lines so as to have formed geometrical figures of fixed position, we have no hesitation in saying that it would have been a most remarkable work.

At the same station for the purpose of communicating between the main rails and the carriage house, which is parallel to them, a siding is carried from the main line to the front of the carriage house, as shown in fig. 9. The latter contains four lines of ways running from

Fig. 9.



from front to rear, and outside of it are five more lines of way for the luggage trucks. Along the front of the carriage house, and at right angles with the rails is a pair of rails laid to a gauge of 7 ft. 4 in., and 9 inches below the lines of way, upon which runs a carriage, shown in figs. 10 and 11. On the top of this carriage, and on a level with the

Fig. 10. Plan of Truck.

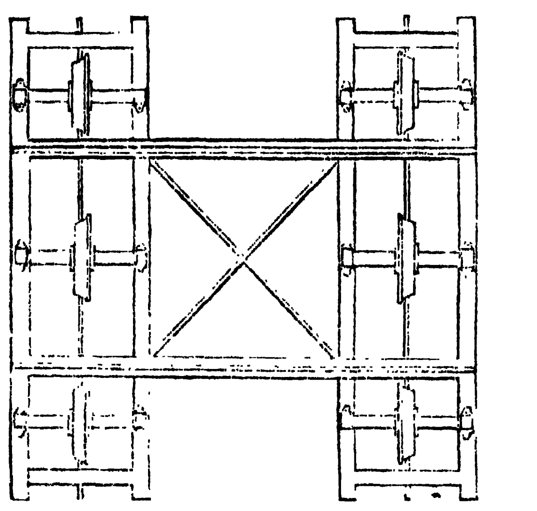


Fig. 11. Section of Truck.

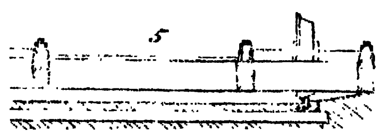
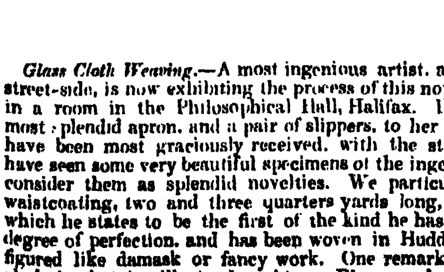


rails of the main line are corresponding rails supported on timber framing, which is suspended to the axles of six cast iron wheels, 20 inches diameter. These wheels run on the 7 ft. 4 in. gauge for the purpose of removing the carriage or truck which is put upon the frame to any pair of the reserve rails in the carriage-house. This saves the trouble and expense attendant upon turn tables opposite to each pair of rails.

Fig. 12.



The engine house is a polygonal building containing twelve lines of way, in the middle of which is a turn table communicating with the whole. The construction of the points is shown in the annexed figure 12.

Glass Cloth Weaving.—A most ingenious artist, a Mr. Barker, from Ossett-street-side, is now exhibiting the process of this novel species of manufacture, in a room in the Philosophical Hall, Halifax. He has lately forwarded a most splendid apron, and a pair of slippers, to her Majesty the Queen, which have been most graciously received, with the strongest approbation. We have seen some very beautiful specimens of the ingenious inventor's skill, and consider them as splendid novelties. We particularly noticed a piece of waistcoating, two and three quarters yards long, and half a yard in width, which he states to be the first of the kind he has been able to bring to any degree of perfection, and has been woven in Huddersfield. It is beautifully figured like damask or fancy work. One remarkable circumstance in glass cloth is that it will stand washing. We were shown a piece of pure white, which has six times undergone that process. We hope the ingenious and persevering man who has already spent two years and a half in bringing his invention to a state fit to meet the public eye, will reap his reward for his invention.—*Halifax* "

ON THE ECONOMY OF FUEL IN LOCOMOTIVES CONSEQUENT TO EXPANSION AS PRODUCED BY THE COVER OF THE SLIDE VALVE.

SIR—With a view to economy of fuel, locomotives are now generally constructed so that the slide valve shall have what engineers call "cover on the steam side," the effect of which is, that steam is admitted to the cylinder during only a part of the stroke of the piston, and during a part of the remainder that steam by expanding to occupy a greater volume propels the piston; which expanding increases the work performed by a given quantity of steam to an extent depending on the ratio of that part of the stroke, during which the steam is admitted to the cylinder, and that part of it during which the steam is expanding; and as the consumption of fuel is dependent on the work performed by a given quantity of steam, an analytic investigation of the cover of the slide valve is the object of the following.

In the figure* let F' G, represent the connecting rod, F' E the engine crank, E A' the eccentric crank, F E the engine crank when the piston commences its stroke, and E A the corresponding position of the eccentric crank, B C, D C valve levers. Put E A' $= a$, E F' $= d$, cover of valve $=$ c, lead of valve $= l$, B C $=$ D C. To diminish complication neglect the radiation of the eccentric rod and connecting rod, which may be done without sensible error, since their length is great in proportion to the lengths of the cranks.

Draw L E perpendicular to E B, and any angle L E A has its sine proportional to the distance that the valve is from its position when L E A $= o$. When the piston is commencing its stroke the valve is open, the quantity (l), and therefore it has travelled the quantity ($l + c$) from its position when L E A $= o$; hence $a \times$ sin. L E A $= l + c$

$\therefore$ sin. L E A $= \frac{l + c}{\ }$, and cos. L E A $=$

Again, if the engine crank travels over any angle (φ) from its position, F E the descent or progress (y) of the piston is equal to d × ver- and $\sin \phi = \sqrt{\left(\frac{2y}{d} - \frac{y^2}{d^2}\right)}$. The travel ($x$) of the valve corresponding to the travel (y) of the piston, is equal to (a sin. (L E A $+ \varphi$) $- a$ sin. L E A), $\therefore \frac{x}{a} =$ sin. L E A cos. $\varphi +$ cos. L E A sin. $\varphi -$ sin. L E A, and by substituting for the functions of the angles their values found above, and reducing we get

$$\frac{2y}{d} - a^2 \frac{y^2}{d^2} - (l + c)^2 \frac{2y}{d},$$

an equation expressing the relation of (x) and (y) in terms of known quantities.

When the piston begins its stroke the valve is a little open, and steam continues to enter until the valve in its retrograde motion shuts the passage; expansion then commences and continues until the eduction passage is opened. When the eduction passage is opened on one side of the piston it is shut on the other, which gives rise to the compression of steam on the educted side of the piston, and this compression continues until the valve opens for the lead of the next stroke.

In figure let A B C D be a steam cylinder, stroke $=$ A D $= 2\,d$, $a' =$ distance from commencement of stroke to commencement of expansion, $b =$ distance from commencement of stroke to end of expansion; $c' =$ distance from commencement of stroke to position of piston when the valve opens for the lead of next stroke. To find by the above equation the travel of the valve corresponding to the travel (a') of the piston substitute $x = -l$, for the travel corresponding to (b) $x = -(l + c)$,

* The figure is not quite correct; the line should be drawn from f to e and not from f to a'.

for the same in relation to (c') $x = -(l+2c)$. And we have

$$x = -l \text{ and } y = a' = \frac{d\,(a^2 - lc - c^2) + d\sqrt{(a^2 - lc - c^2)^2 - a^2 l^2}}{a^2} =$$

$$d\,(1 - lc - c^2) + d\sqrt{\left\{(1 - lc - c^2)^2 - l^2\right\}}. \quad \text{When } a = 1$$

$$x = -(l+c) \quad y = b = \frac{a^2 d + d\sqrt{a^4 - a^2 (l+c)^2}}{a^2} = d + d\sqrt{1 - (l+c)^2}$$

$$x = -(l+2c) \quad y = c' =$$

$$\frac{d\left\{a^2 + lc + c^2\right\} + d\sqrt{\left\{(a^2 + lc + c^2)^2 - a^2 (l+2c)^2\right\}}}{a^2} =$$

$$d\,(1 + cl + c^2) + d\sqrt{\left\{(1 + cl + c^2)^2 - (l+2c)^2\right\}}$$

Having now found the values of $(a'\ b$ and $c')$, we must next find the effect gained by the expansion of the steam from $(a'$ to $b)$, and the effect lost by the compression of the steam from $(b$ to $c')$. But expansion may take place in two ways, the operations of which are quite distinct, first, the cylinder may remain of the same volume and the steam be increased in pressure before entering them; or, the cylinders may be enlarged and the pressure of the steam be constant, which is the plan virtually adopted in locomotives; for those of them that do not work by expansion when properly constructed, are so made that their cylinders are not capable of consuming a greater volume of steam than the boiler can furnish of the greatest safe pressure.

The eduction passage being shut by the time that the piston arrives at the end of (b), saves, or at least prevents from flying to the atmosphere a quantity of steam of a pressure (t), that fills $(2d - b)$ of the cylinders, which at a pressure (p) would fill $\frac{(2d-b)t}{h}$ of the cylinders hence when the steam is cut off at (a'), there is only admitted so much fresh steam as fills $(a' - \frac{(2d-b)t}{h})$ and since the quantity of fresh steam admitted must (whatever the expansion is) be constant, we have $s\,(a' - \frac{(2d-b)t}{p}) = 2d \times 1$, $\therefore s = \frac{2dp}{a'p - 2dt + bt}$, (s) being the area of the piston.

Again in figure let (x) be any portion of the stroke greater than (a), and less than (b), and let p' be the pressure into which the steam has expanded at the end of (x) then $x : a' :: p : p'$, $\therefore p' = \frac{ap}{x}$ $\therefore$ effective working pressure $= \frac{ap}{x} - t$.

$\because$ differential of work performed $= d$ efficiency $= s\,(\frac{ap}{x} - t)\,dx$,

$\therefore$ efficiency in part (b) of the stroke $= s\,ap\,(\log\frac{b}{a} + 1) - s\,t\,b$.

Again, for the effect of compression caused by the shutting of the eduction passage let (x) (measuring from DC) be any portion of the stroke between $(b$ and $c)$, and (p') the pressure, to which the confined steam has been compressed, then $x : 2d - b :: t : p'$ $\therefore p' = \frac{(2d-b)t}{x}$, $\therefore$ effective working pressure $= \frac{(2d-b)t}{x} - t$ $\therefore d$ efficiency $= \left(\frac{(2d-b)t}{x} - t\right) s\,dx$, $\therefore$ whole effect of compression $=$

$$s\,t\,(2d-b)\left\{\log.\frac{2d-b}{2d-c} - 1\right\} + s\,(2d-c)\,(p+t.)$$

By deducting the effect of compression from the efficiency of the part (b) of the stroke, we have whole work performed $=$

$$s\,a'p\left(\log.\frac{b}{a'} + 1\right) - s\,t\,b - s\,t\,(2d-b)\left\{\log.\frac{2d-b}{2d-c} - 1\right\}$$

$- s\,(2d-c)\,(p+t)$. Put $2d = 1$, $t = 1$ and (p) is then expressed in multiples of (t). $\therefore$ whole work performed $=$

$$s\,a'p\left(\log.\frac{b}{a'} + 1 - s\,b - s\,(1-b)\left\{\log.\frac{1-b}{1-c} - 1\right\}\right.$$

$$- s\,(1-c)\,(p+1).$$

$$\text{But } s = \frac{p}{a'p - 1 + b}$$

$\therefore$ Whole work performed $= \frac{p}{a'p + b - 1}$ multiplied into

$$\left\{a'p\log.\frac{b}{a'} - (l-b)\log.\frac{1-b}{1-c} + a'p - 2b - p + pc + c.\right\}$$

An expression for the work performed by a unit of volume of steam, formed of known quantities, or rather of quantities which become known when (l) the lead, and (c) the cover of the valve are given.

Let the safety valve be so loaded that (p) is equal to (s), and let the lead (l) of the slide valve be nothing, and the cover (c) be nothing. Then $a' = 1$, $b = 1$, $c' = 0$, $\therefore$ whole work performed $= p - 1 = 4$, which is exactly what another mode of proceeding gives for when the valve has no cover and no lead, the work performed is evidently $= 2d\,(p - t)\,s$. But $2d = 1$, $t = 1$, and when the valve gives no expansion $s = 1$, therefore work performed $= p - 1 = 4$.

Again, let the lead (l) be equal to $\frac{1}{8}$ of the breadth of the port, and the cover (c) equal to $\frac{1}{4}$ of the breadth of the port. And then
$a' = 0{\cdot}888$ $\quad b = 0{\cdot}9545$ $\quad c' = 0{\cdot}992$ $\quad \therefore$ whole work performed $= 4{\cdot}2378$.

Again, let $l = \frac{1}{8}$ breadth of port, $c = \frac{1}{2}$ breadth of port, and then
$a' = 0{\cdot}656$ $\quad b = 0{\cdot}873$ $\quad c' = 0{\cdot}99$ $\quad \therefore$ whole work performed $= 4{\cdot}8966$.

Again, let $l = \frac{1}{8}$ breadth of port, $c = \frac{3}{4}$ breadth of port, and then
$a' = 0{\cdot}2884$ $\quad b = 0{\cdot}7$ $\quad c' = 0{\cdot}975$ $\quad \therefore$ whole work performed $= 7{\cdot}1$.

Again, $l = \frac{1}{100}$ breadth of port, $c = \frac{3}{4}$ breadth of port, and then
$a' = 0{\cdot}43$ $\quad b = 0{\cdot}825$ $\quad c' = 0{\cdot}999$ $\quad \therefore$ whole work performed $= 4{\cdot}97$.

Hence the following conclusions:—In a locomotive in which the stroke of the cylinder is 18 inches, and breadth of port 1½ inches, if the work it performs with a ton of coke when the valve has no cover be called 1; then by giving the valve ⅛ of an inch of lead, and ⅜ of an inch of cover, the steam will be cut off at 15·98 inches from commencement of stroke, and the work performed by a ton of coke will be 1·0591.

Again, by giving the valve ⅛ of an inch of lead, and ¾ of an inch of cover, the steam will be cut off at 11·8 inches from commencement of stroke, and the work performed by a ton of coke will be 1·2241.

Again, by giving the valve ⅛ of an inch of lead and 1⅛ inches of cover, the steam will be cut off at 5·2 inches from commencement of stroke, and the work performed by a ton of coke will be 1·75.

Again, by giving the valve $\frac{1}{100}$ of the breadth of the port of lead, and 1⅛ inches of cover, the steam will be cut off at 7⅞ inches from commencement of stroke, and the work performed by a ton of coke will be 1·242.

In the two last examples the cover of the valve is the same, but in the latter the lead is much less than in the former, which has diminished the efficiency of a ton of coke from 1·75 to 1·242, or nearly in the ratio of 3 to 2; and if the lead was still a little less the advantage gained by the cover would be altogether neutralized. Hence it appears that the lead is an important feature in the construction of the slide valve, and might be a good subject of enquiry as to what relation it ought to bear to the cover so as not to interfere with the operation of expansion.

I am, Sir, your obedient servant,

J. G. Lawrie.

Cartsdyke Foundry, Greenock,
June 27, 1841.

N.B.—Should you consider this letter worthy of insertion in your Journal, I shall probably request insertion of another in continuation of the same subject, in which the lead will come under consideration.

J. G. L.

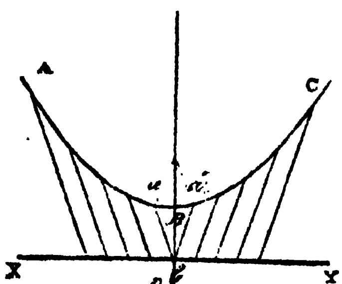
REMARKS ON MR. DREDGE'S SUSPENSION BRIDGE.

Sir—Feeling some interest in the subject of suspension bridges, I was gratified to find in a recent number of your instructive publication, a description of Mr. Dredge's newly invented suspension bridge, represented as offering such superior advantages, in all the essential particulars of strength, durability, and economy of construction. At the same time, however, I was somewhat disappointed when, having perused the article in question, I found that no attempt had been made to demonstrate the possession of such desirable qualities, by a reference to those well known principles and laws which govern the forces to which a suspension bridge is subject, and not having subsequently seen in the Journal or other publications, any such investigation of the subject, I am induced to forward to you the few remarks which follow, in the hope that you may think them deserving of a place in your forthcoming number.

The two characteristic features of Mr. Dredge's bridge appear to be the unequal thickness of the chains which taper from the middle point of the curve to its extremities, and the inclined position of the suspension rods.

A chain whose thickness is equal throughout being suspended from its extremities, assumes the form of a curve which has received the name of the Catenarian curve; the tension to which the chain is subject by its own weight, varies as the secant of the angle made by the tangent on any point, with a horizontal line, or, which is the same thing, as the secant of the angle contained by the tangent and ordinate. It is obvious, therefore, that the tension will be least at the lowest point of the curve, and increase towards the points of attachment, where it will be a maximum. In a chain of equal thickness its strength cannot therefore be proportionate to the stress to which it is subject, and it therefore naturally occurs that the chain should not be of equal thickness throughout, but be increased in sectional area from the lowest point of the curve to the highest. By mathematical analysis, the form of chain has been determined whose sectional area is always proportional to the tension; and a chain constructed upon this principle has, I believe, been actually adopted for the large suspension bridge erecting over the Avon by Mr. Brunel.

The idea of a chain of varying thickness is not therefore *new*, and as regards Mr. Dredge's bridge, the utility of the form of chain he has adopted appears to depend upon whether the sectional area varies as the tension at each point. Considering the chain in the first instance, as simply affected by its own weight, this point would be determined by comparing its form with that in which it is known the sectional area varies as the tension. I have not at this moment with me the means of making the comparison, but it is evident that if the two forms are identical, there is no *novelty* in this part of the invention, and if they are not, Mr. Dredge has proposed a form which is inferior to one that would always be employed when rendered proper from attendant circumstances. Except in large bridges it has not, however, been considered desirable to vary the thickness of the chain according to the tension, as the difference of thickness at different points is found too inconsiderable to merit attention. It seems, therefore, extremely probable that Mr. Dredge by varying the thickness of his chain in a very rapid ratio has far exceeded the increased thickness required by the tension.



Abstracting now for the sake of argument, the effect produced by the weight of the chain itself, and regarding only that occasioned by the tensions of the rods, it will be observed that these tensions are much increased by the inclined positions which the rods are made to assume. This is illustrated in the figure. A B C is the chain, X Y the horizontal platform, and $a\ b$, $a'\ b$, &c. the suspension bars. Let us suppose that the tension of the bars has been adjusted so as to be equal for all, and that the weight of the platform is known. If it be homogeneous in its structure, the centre of gravity will be at b, and the weight may be conceived as a force B D, acting in a vertical direction through this point. Each of the pairs of forces acting along the rods $a\ b$, $a'\ b$, &c., will have a resultant acting in the direction D B, opposite to that in which gravity acts. These resultants will also be equal to one another, and, supposing the platform suspended from two chains, their sum will be a force equal in magnitude (though opposite in direction) to half the force B D, the weight of the platform. Hence if this weight be given, we obtain the resultant of each pair of forces acting along oppositely inclined rods, by dividing half this weight by half the number of rods attached to one chain. Let the angle made by the rods with the vertical be θ, w half the weight of the platform, and n the number of rods, then the resultant of each pair of forces $= \frac{w}{\frac{1}{2}n}$.

And b the tension of each rod is $\frac{1}{2} \times \frac{w}{\frac{1}{2}n} \times \frac{1}{\cos.\theta} = \frac{w}{n \cos.\theta}$. Hence $b \propto \frac{1}{\cos.\theta} \propto \sec.\theta$, and is consequently least when $\sec.\theta$ is least, *i. e.* when $\sec.\theta = 1$, or the rods are vertical. This arrangement, then, is disadvantageous, since it not only requires that the rods should be made of increased size to resist the increased tension to which they are exposed, but subjects also the chain to increased pressure from the rods in the ratio of $\sec.\theta : 1$.

Although the forces acting upon the two halves of the chain are inclined in opposite direction, it will be observed that the two halves are precisely similar, for if we imagine one-half to revolve round the axis B D, till the plane in which it is situated, coincides with the plane of the other half, the suspension rods of the two halves will exactly coincide, and consequently as the forces produced by them are equal, coincident in direction, and have similar points of application, the curves produced will be identical in all respects. Being produced by equal and parallel forces uniformly distributed along the curve, they belong to a Catenary whose ordinate is at right angles to the directions of the rods. Hence the tension caused by the action of the rods varies according to the law already stated, and if it be required to equalize the sectional area and tension of the chain, it must be constructed of the form already determined for the Catenarian Curve. Whether, then, we consider the effect of the weight of the chain itself, or the pressures produced by the suspension rods, the chain should be constructed upon precisely the same principles as in the ordinary suspension bridges. For these reasons I cannot but regard the plan proposed by Mr. Dredge as inferior to the ordinary method of construction, and I have accordingly, a contrary opinion having been maintained in your pages, ventured to offer these remarks to the consideration of your readers.

I am, Sir, your's obediently,

G. F. F.

Sandon Bury, July 14, 1841.

MR. PARKES' NEW THEORY OF THE PERCUSSIVE ACTION OF STEAM.

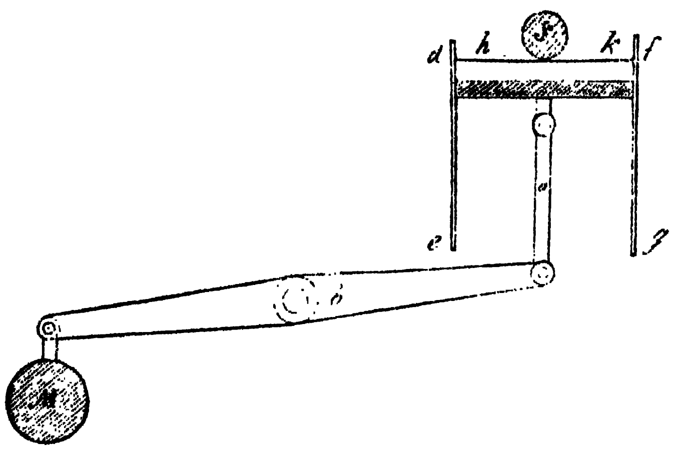
In this highly enlightened age, when long established theories crumble to dust under the all-searching glance of modern science, and the discoveries of our fathers, eclipsed by the surpassing splendour of the productions of modern genius, hide their diminished heads, it would perhaps be a mark of weakness of intellect to express astonishment at any new doctrine, however contrary it may be to our preconceived notions, or apparently so to the fundamental laws of nature. If, then, we were not surprised, at least our interest was excited in a high degree by the perusal of Mr. Josiah Parkes' Paper "on the Action of Steam in Cornish Single Pumping Engines," published in the Transactions of the Institution of Civil Engineers, Vol. 3, Part 4, wherein he developes, or rather announces a new principle of Action of Steam in Cornish Engines, which seemed at the first glance to point out a means of increasing almost indefinitely the dynamic effect of steam in steam engines; though why he considers it to operate in these engines only we know not—we are of opinion, that, if it obtains in them, it should obtain *à fortiori* in Locomotives, where the density and velocity of the steam entering the cylinder are so much greater. This new Principle is denominated by its discoverer the *Percussive Action of Steam*, and is announced in the following words, page 268:

"Steam, in its action on the piston of an engine, has hitherto been considered as simply exerting elastic force."

"Steam, however, possesses another important property, equally inherent in its nature with pressure and expansibility. This property is the velocity and consequent momentum due to steam of high elasticity: a force which comes into play under the peculiar conditions of a Cornish engine. The velocity of steam, in passing from a dense into a rarer medium, is immense; and the momentum of this steam must be very considerable. On the sudden and free communication effected between the cylinder and boiler of a Cornish engine, the steam in the cylinder receives an instantaneous action, proportionate, in amount, to the velocity of the entering steam, and this action, by the property of fluids, is transmitted to the surface of the piston. This action, thus transmitted to the piston, and due to the communication suddenly established between the highly elastic steam in the boiler, and the steam in the cylinder, may be likened, I conceive with great propriety, to the force of percussion; by which term I propose to distinguish it from the action of the steam's simple elastic force."

This force is illustrated in a note at the foot of the page by a comparison with the Pile-driving Machine and Hydraulic Ram; we think the following illustration much more appropriate.

Let $d\ e\ f\ g$ in the annexed diagram represent the section of a cylinder, in which the piston p can move air-tight, let the latter be connected by a link a to one end of the vibrating beam b, a mass M being



suspended at the other end; further, let $h\ k$ represent an inflexible circular plate fitting air-tight into the cylinder, but supposed to have no weight, and let there be a space c between this plate and the piston p filled with air of a given density.

The piston p being near the top of the cylinder, the circumstances are analogous to these of the Cornish single-acting engine just before the commencement of the working stroke, the air in the space c above the piston representing the cushion of steam against which the piston is brought to rest at the end of the return stroke, the beam b the balanced portion of the moving parts of the machinery, and the mass M the unbalanced portion.

In order to form an idea of the manner in which the momentum of the steam, admitted suddenly above the piston at the beginning of the stroke, is transferred to the latter, and thus increases the effect above what is due to the simple elastic force of the steam, let a mass S (say equal to the mass of steam admitted in the stroke) impinge against the plate $h\ k$ with a given velocity. The result of this impact is, obviously, that the mass S loses a portion of its velocity, and consequently of its momentum, which is transferred to the air contained in the space c, which in its turn, communicates the chief part of this momentum to the piston p, the beam b and the suspended mass M. If the mass S be supposed to strike the plate $h\ k$ with a velocity equal to that of the steam at its entrance into the cylinder of the Cornish engine, its percussive effect may be assumed to be the same as that of the latter, though it will in reality be greater on account of the *simultaneous* action of the whole mass, whereas the mass of steam arrives in the cylinder *gradually*. The interposition of the air c is essential to the perfect conformity of the two cases, for the entering steam no sooner passes the contracted orifice of the throttle-valve, where it impinges, as it were, against the steam already in the cylinder, than it expands and loses the greater part of its velocity, at the same time compressing the steam with which it mingles.

The necessity of adopting this theory (of the Percussive Action of Steam) was forced upon Mr. Parkes by his inability to discover, in the simple elastic force of the steam employed, an amount of power adequate to accomplish the actual duty ascertained to have been performed by several of the Pumping Engines in Cornwall, the facts observed admitting of no question. This is, in our opinion, the only valid argument brought forward by the author in its favour, though he has adduced several others in corroboration, which, however, require the co-existence of the former to give them weight, and even so they are but of a negative character, amounting in substance to this: since the amount of power due to the steam's elasticity alone is less than the amount of work done, an additional quantity of power must be derived from other source; and whence can it be derived but from the instantaneous action transmitted to the piston, on effecting the sudden communication between the steam in the cylinder and that in the boiler.

Assuming the data furnished by experiment to be correct, (and we have no reason *à priori* to doubt their accuracy), the above reasoning appears to be conclusive, at least in so far as the additional power required to realize the observed dynamic effect must be sought in some property of steam distinct from its elastic force; and its Momentum, or rather Inertia, is the only property which suggests itself as capable of supplying any additional amount of power.

Admitting, therefore, the inadequacy of the simple elastic force of the steam to accomplish the work actually performed, and assuming the deficiency of power to be supplied by the Steam's Percussive Action, the next step naturally, is to examine into the causes and effects of this action.

The cause is obvious, and is almost sufficiently explained in the illustration which we have given above. A mass of dense steam passes through the throttle valve at a great velocity, the chief part of which it loses by the time it comes to act by its elastic force upon the surface of the piston. This mass of steam must, therefore, in losing its velocity, impart its momentum to some other body or bodies, through the medium of which it may afterwards be utilized in increasing the dynamic effect of the steam. The body which receives the shock of the entering steam, and transmits its momentum to the moving parts of the engine, is the steam cushion represented in the illustration by the air c, and the entering steam by the mass S. It is this imparting of its momentum which is called the Percussive Action of the steam.

In investigating the effects of this action, our object is to ascertain the amount of momentum transmitted thereby to the piston and other pieces of machinery connected with it, and we looked in vain to Mr. Parkes' work for assistance in this inquiry; there is, indeed, an article (page 269), headed: *Determination of the quantity of Percussive Action*, which commences with the statement that "the dynamic effect, or quantity of action, due to percussion, is discoverable, and assignable for each example: but the only method employed by the author for its determination is that of elimination, that is, by deducting from the total dynamic effect of the steam found in the quantity of work done, the amount due to its elastic force, including expansion, the remainder, which is the deficiency of power according to the ordinary theory, being attributed to the percussive action. In a note at the foot of the same page Mr. Parkes says: "It forms no part of my task to investigate the abstract question of the quantity of this species of force to be obtained from steam; my present purpose is confined to the determination of the effect attributable to it in the three engines subjected to analysis." It is a pity he did not make it part of his task to investigate, not *the abstract question of the quantity of this species of force to be obtained from steam*, but *the practical question* of the quantity which the steam would afford in the three cases under consideration. This inquiry would, doubtless, have been full of difficulties, should the result not turn out to be equal to o, which we much suspect would be the case if the investigation were based on the laws of percussion as laid down in the treatises on Mechanics; and if the new principle is to be established in opposition to these laws, it is necessary first to demonstrate their fallacy; but that this is not the view of the case taken by the author is evident by his merely comparing the percussive action of the steam to the shock of a solid body, without intimating in any way that the laws laid down for solid bodies do not obtain equally with regard to steam. He overlooks, however, the important consideration that the shock of the entering steam is not received immediately by the piston, but by the steam previously occupying the space above it, and likewise that the reaction is necessarily equal to the force of impact.

By reason of this latter condition the entering steam can only part with its momentum as fast as the steam in the cylinder is capable, *by its simple elastic force*, to oppose a resistance, or reaction, equal to the force of percussion. The latter is therefore always strictly measured by the elasticity of the steam in the cylinder, the dynamic effect of which thus includes that due to the Percussive Action. If, then, the Indicator diagram exhibits a faithful representation of the elastic force of the steam as it varies from the commencement to the termination of the stroke of the piston, it must necessarily furnish us with the means of determining the whole amount of dynamic effect which can be obtained therefrom. It may also be observed that the effect of the Percussion is transmitted, "by the property of fluids," to the Indicator piston as well as to the working piston, so that, even if there were a Percussive force which acted on the latter in addition to the elastic force of the steam, its influence, being felt by the former also, would be indicated in the diagram by an additional elevation of the pencil.

The above discussion convinced us, as it may also some of our readers, and perhaps Mr. Parkes himself among others, that the difference observed between the amount of power due to the elactic force of the steam and the duty actually performed by the engines subjected to analysis cannot be attributed to the Percussive Action of the steam; and, as there appears to be no other source of power to which it can be ascribed, we are compelled to conclude that the supposed difference does not exist in fact, and consequently that either the experimental data, or the calculations based upon them, are erroneous.

We have said above that we had no reason *à priori* to doubt the accuracy of the observations, and we will therefore now examine into the details of Mr. Parkes' calculations relating to the Huel Towan engine, with the view of discovering whether the discrepancy observed between the power developed by the simple elastic force of the steam and the actual work done be not attributable, either wholly or in part, to some error in his deductions from the data furnished by observation.

Mr. Parkes says (page 261): "The absolute resistance consists of the weight which performs the return stroke, plus the value of engine and pitwork friction, and of the elasticity of the uncondensed steam." To this should be added, for each forcing pump, the weight of a column of water whose base is equal to the sectional area of the plunger and altitude to the mean height of the bottom of the plunger above the level of the water in the cistern whence it is drawn, and for each lifting pump, the weight of the whole column lifted, from the level of the water in the cistern; and we should deduct the amount of assistance, though small, given by the atmospheric pressure on the top of the piston rod.

We are not informed of the value of any of these quantities, except the last, from direct experiment, but we know that the weight which performs the return stroke is necessarily slightly in excess of that of the average column of water raised, augmented by the friction of the water and machinery, and the difference between the atmospheric pressure and that of the steam, during the return stroke, on the area of the piston rod; and the excess (which is necessary to set the engine in motion with its load of water) is counterbalanced at the end of the stroke by the cushion of steam which brings the engine to rest.

Mr. Parkes substitutes for this weight, in his calculations, the water load, which, he says, can alone be termed a positively ascertained quantity; but in computing this load he commits two errors, which, however, compensate each other. He calls the mean diameter of the pumps 14·625 inches, instead of 14·968, which renders it necessary to assume a cubic foot of water to weigh 65·47 lb., instead of 62·5 lb., in order to make the water load equal to 686664 1 lb.. in which he agrees with Mr. Henwood, by whom the experiment was made. It is permitted, in calculating the effective resistance on the piston, to use the total height of the column of water, since it is equal to the sum of the average heights mentioned above; so that the absolute resistance will be equal to the weight of the total column of water raised, *plus* the friction of the water in the pipes, twice the friction of the machinery, and the elasticity of the uncondensed steam, *minus* the difference between the pressure of the steam during the return stroke, and that of the uncondensed steam during the working stroke, on the area of the piston rod. The diameter of the piston being 80 inches, and that of the piston rod 7 inches, the area of the former minus that of the latter, or the effective area of the piston, is equal to 4988·08 square inches, and the resistance on the piston due to the water load is consequently 11·01 lb. per square inch. (Mr. Henwood by some mistake made it only 10·2 lb. per square inch, which he also called the whole resistance of the engines). The elasticity of the uncondensed steam is estimated at 1·25 lb. per square inch, and that of the steam in the cylinder during the return stroke appears, by Mr. Henwood's indicator diagram, to have been about 6·4 lb. The difference between these two last quantities, reduced in the ratio of the area of the piston rod to the effective area of the piston, becomes 0·04; and we find the whole resistance per square inch of the piston (assuming with Mr. Parkes that the frictions, the actual amount of which we have no means of ascertaining, cause a pressure of 5·75 lb. per square inch) equal to

$$11{\cdot}01 + 5{\cdot}75 + 1{\cdot}25 - 0{\cdot}04 = 17{\cdot}87 \text{ lb.}$$

We think, with Mr. Parkes, that this amount is by no means exaggerated, but more likely the reverse, particularly in the evaluation of the frictions, and must therefore conclude that the error, if any, must be in the calculation of the power from the indicator diagram. Now we have satisfied ourselves that the mean elasticity indicated by the diagram would not produce sufficient power, so that we have no alternative left but to prove the diagram false or to confess ourselves unable to account for the facts observed by Mr. Henwood.

If we admit the pressures to have been as shown in the diagram, and that the equilibrium value was closed when the piston was 9 inches from the end of the return stroke, we must either suppose the unreasonably large space of 68·089 cubic feet to have existed below the piston at the bottom of its stroke, or, (if we allow thirty cubic feet,) we must assume a waste of 7·4 per cent. of the water expended. On the latter hypothesis, the volume of steam of 6·4 lb. pressure discharged from the cylinder every stroke was 352·886 cubic feet, which is the capacity of the space below the piston when the equilibrium valve is closed, and the volume remaining above the piston was 25·979+c, calling c the capacity of the space above the piston when at the top of its stroke, or the volume of the steam-cushion. The whole quantity of steam in the cylinder of this elasticity is therefore equal to 378.865+c, and its relative volume 3668. The space it occupied before the equilibrium valve was opened was 346·393+c, its elasticity was 7 lb. per square inch, and its relative volume 3877, so that we can find the value of c from the following proportion,

$$32{\cdot}472 : 291 :: 346{\cdot}393+c : 3877,$$

whence

$$c = 30{\cdot}438 \text{ cub. ft.}$$

The absolute volume of the steam which formed the cushion was, before compression, 56·417, and its relative volume 3668; after compression its absolute volume was 30·438, which makes its relative volume 1979, and its elastic force 12·48 lb. instead of 10·7, as shown by the diagram. Mr. Parkes gives 9·176 cubic feet as the value of c, which would evidently increase the difference between the calculated and the observed pressure of the steam-cushion.

The volume of steam of 7 lb. pressure in the cylinder just before opening the equilibrium valve is 376·831 cubic feet, and the volume occupied by the same steam when the piston had described one fourth of its stroke, and the admission valve was quite shut, was 117·036 cub. ft., so that the relative volume of the steam was then $3377 \times \frac{117{\cdot}036}{376{\cdot}831} = 1049$, and its elasticity 24·87 lb. per square inch; according to the indicator diagram it was only 20·4 lb.

We have no means of testing the correctness of the pressures marked by the indicator during the period when the admission valve was open, but the above calculation suffices to prove that the diagram is far from furnishing an exact measure of the steam's elastic force at least in the instance quoted, and that if the whole, or nearly the whole, of the water expended passed through the engine in the form of steam, it was sufficient to produce, by its simple elastic force, a dynamic effect equal to the work actually performed, particularly if the volume of the steam-cushion was only 9·176 cubic feet as stated by Mr. Parkes, and which accords with Mr. Henwood's datum of the volume of steam used per stroke.

Mr. Parkes has rendered some part of his paper rather difficult to understand by an ambiguity of expression relating to the expansion of the steam, accompanied in one place by an apparent contradiction in the facts. He says (page 264), "it is evident that the effect of a given weight of water as steam, consumed during a stroke, will be the same, whether that steam be regarded as having been all enclosed between the piston and cylinder cover, before the piston were permitted to move, when it would expand nearly uniformly from the beginning to the end of the stroke; or, whether it be considered as having been admitted during a portion of the stroke, at some pressure greater than the resistance, and then expanded through the remainder of the stroke."

What the author meant by this we cannot guess; taken literally, it is obviously false, and that it was not intended to be understood so, appears by the calculation of the effective power in the sequel. He continues:

"But, the value of expansion consists, virtually, in the quantity of action derived from the steam, after *it forms an equilibrium with the resistance*..... By tracing it, first, through the space of the cylinder, where *it would barely balance the resistance*; and secondly, through the space during which *it suffered expansion below that pressure*, a true measure of the respective and total quantities of action developed by it, expansively and unexpansively, will be obtained."

The expressions in italics imply that the expansive is separated from the unexpansive part of the stroke at the point where the pressure of the steam is equal to that of the resistance; but the numbers quoted in the next page prove that such was not the author's meaning, for he says, "when the piston of the Huel Towan engine had passed through 50·7 out of 120 inches, which was its total length of stroke, the steam's elastic force and the resistance counterpoised each other." Now we are informed that the resistance was 18·01 lb. on the square inch, and the indicator diagram shows a pressure between 13 and 14 lb. at the point mentioned; but in the diagram of the steam's action at page 294, a pressure of 18 lb. is marked at that point, and the steam and resistance are said to be in equilibrio. We are unable to account for this discrepancy.

A series of well-conducted experiments with Cornish single-acting engines would not only be very interesting with regard to the working of these engines, concerning which so much doubt is still entertained, but would doubtless throw a great deal of light on the general theory of the steam-engine, since they afford facilities for making observations which double-acting engines do not admit of.

A New Line of Atlantic Steamers.—The *St. John's N. B., Herald* informs us that the English Government is about contracting for an additional line of steamers to the North American colonies, which will give a weekly communication with England. The new line will be likely to run direct to St. John's, such being Sir William Colebrook's wish, while the present line will continue to run to Halifax. We presume the new line will be extended from St. John's to this port.—*New York Evening Post.*

BRONZE GATES.

Fig. 1.—Elevation of Gate.

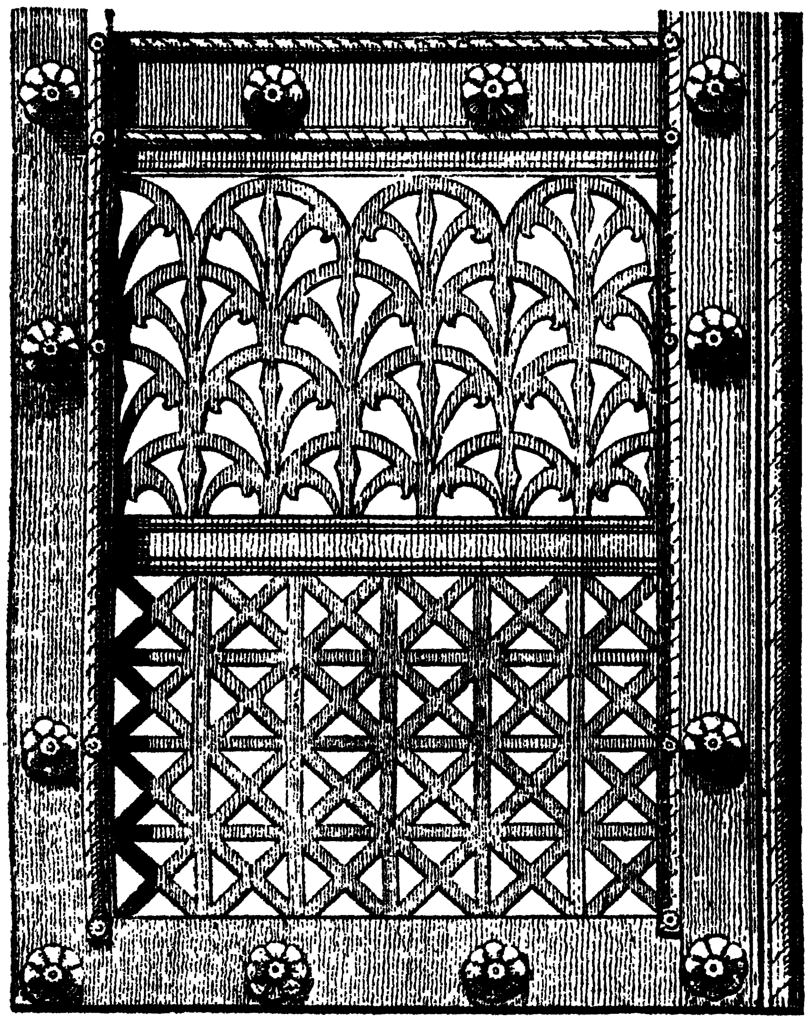


Fig. 3.—Elevation.

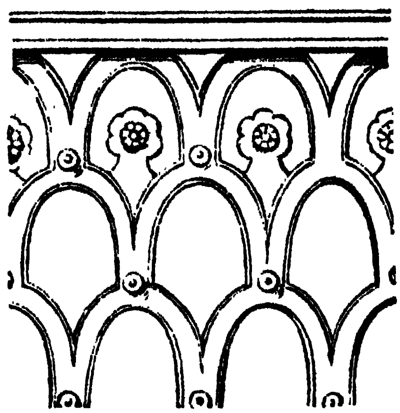

Fig. 4.—Section.

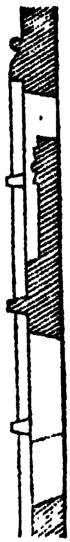

Fig. 2.—Plan of Gate.

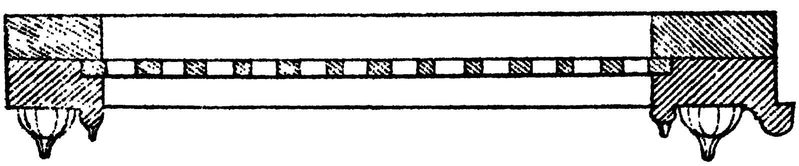

Fig. 5.

The "*Revue Generale*" intends to give a series of designs of bronze gates selected from the best examples to be found in France, some of which we propose occasionally to give in the Journal. The annexed engravings represent the celebrated bronze gates of the Cathedral of St. Mark, at Venice.

Fig. 1 is a double panel of one of the gates; two styles and two cross rails, ornamented with projecting nailheads and torus mouldings enclose the principal panel, which is divided into two open compartments by a horizontal rail; the lower part is an exact copy of ancient cross-barred work, and the upper presents an imitation of the *imbrications* often made use of by the ancients; the hollow formed by each of the semicircles is occupied with a kind of fleur-de-lis, such as is generally depicted during the middle ages. The ensemble of this com-[illegible] is original, and perfectly answers the object proposed.

A horizontal section (fig. 2) shows the arrangement of the different [illegible] of this gate, the thickness of the panels, and the projection of

Fig. 3, is a fragment of another panel of the same church, which also exhibits Roman imbrications; in the upper row the artist has introduced some detached flower ornaments, which have a good effect. Fig. 4 is a vertical section of this fragment.

Numerous lion's heads, formerly gilt, are placed in the imbrications which decorate this gate, one is represented in fig. 5. The style of sculpture would serve to point out the age of the gates, were we not aware that they were cast in the 11th century, when St. Mark's was finished.

The annexed designs may be arranged in a variety of ways, so as to form some excellent examples for iron gates, railings, &c., either by repeating the same panel, or taking two panels of one design and one panel of the other, or *vice versa*. Likewise by omitting any part of the ornaments, or all, or introducing others, and the same framework may be applied either vertically or horizontally.

CANDIDUS'S NOTE-BOOK.

FASCICULUS XXIX.

"I must have liberty
Withal, as large a charter as the winds,
To blow on whom I please."

I. CAMPBELL'S Vitruvius Britannicus contains a design for a church, by himself,—"an original invention," as he calls it,—which is nothing more than an Ionic prostyle, pseudo-peripteral along its sides, so far tolerably Grecian as to its plan, but a mere parody of Grecian architecture, as to style. The east end has a large Venetian window, which is the only one in the building, but he says, it would give sufficient light to the whole interior; and if so, it is a pity the hint has never been taken by any one else for structures of that class, instead of cutting up and crowding their designs with a multiplicity of windows, that become so many blemishes, as is the case with St. Martin's Church. In all the various styles of pointed architecture, windows are principal and almost indispensable features, they and doorways being the chief source of decoration, and of character; whereas they are so much at variance with either the Grecian or the Roman style, if intended to be kept up with tolerably consistency, as to be hardly admissible, more especially where the general idea is affected to be borrowed from that of an ancient temple, whither it be a peristylar or merely a prostyle one. Its windows detract very materially from the design of St. Pancras' Church; and when it is viewed obliquely, the flank of the building produces a harsh and disagreeable contrast with the portico—which last is not disfigured, as too frequently happens with any apertures of the kind. That there is authority for windows in ancient structures, is undeniable, because those of St. Pancras are copied from the same edifice as the order itself, and the ornamental details. But then, the application of such features is altogether different from what it is in the original precedent. In the last there are only three at one end of the exterior; in the professed copy there is a range along each side, besides a series of smaller ones below, which gives an air of insignificance to the whole. Were there no other objection against them, it is no small one that they quite contradict the portico, indicating as they do not only that the interior is divided into two floors, but that the ceiling of the lower one or ground floor, is not half so high as the doors! Without entering the church, we may guess that there is in reality no such division, but that the lower windows, are merely intended to admit light beneath the galleries. The question then becomes, what occasion can there be for windows just there, provided the interior be otherwise sufficiently lighted, as it certainly might be? What occasion in fact for side windows at all —unless indeed they can be made to contribute advantageously to external effect—when they might be dispensed with altogether, and a building of the kind—a single spacious room—be lighted entirely from the ceiling, in almost any way that would best suit the particular design?—If, for instance, there is a dome, let the light proceed chiefly, if not exclusively, from that part of the ceiling plan, instead of the concave of the dome being in comparative gloom and darkness, as is the case at St. Paul's. One advantage attending the exclusion of side windows—which except in the Gothic style are more injurious than conducive to effect—would be that the walls being solid, noise from the street would be obstructed. Whether smart Sunday bonnets in the seats under the galleries would be seen to so much advantage as at present, is a different consideration—doubtless a most important one in itself. The galleries themselves are a nuisance; and never have I met with an architect who did not cordially agree with me on that point. The pew-system is not much better, though mightily in favour with

"A loyal Church, that keeps the rich and poor
Duly apart, nor blends the lord and boor.
'Tis sweet to witness *pews*, nor mean, nor scant,
For those who pay,—*free seats* for those who can't," &c.

These lines are from a clever poem which has just issued from Albemarle-street—hitherto considered the seat of High-Church orthodoxy, and conservatism!

II. In regard to the church I have just been speaking of (St. Pancras,) I cannot help thinking that the design would have been very materially improved, had the two caryatic wings, been placed at the west instead of the east end; so as to combine with the portico, and form an extended façade. A very striking composition might have been so produced, one no less distinguished by picturesque variety than by its richness. Those wings would have balanced the tower above, and given a pyramidical outline to the whole structure as viewed in front. Neither would it have been the least recommendation of such arrangement, that the wings would have served to screen the insipid side elevations. It would however have been further desirable that instead of being merely stuck on to the body of the edifice, as at present, they should be made to unite with it symmetrically, for at present the upper line of the cornice ranges with no other line, but falls about midway of the windows.

III. Caryatides or *anthropostyle* supports to an entablature, as they may very properly be described, entirely upset the *old-women* critics' fudge as to the different orders being proportioned after the human figure, their proportions being more robust than those of the "manly Doric." Whether these columnar ladies were matrons or virgins, is a point I leave to be settled by the more curious,—and indeed, I almost wonder that no one should as yet have given us some learned twaddle in regard to it;—but it is certain that they are by no means of that maypole appearance which those dames must have exhibited, who stood for models of Ionic and Corinthian columns. After all it is possible that the Greeks borrowed the idea of Caryatides from Holland, for they are most indisputably very Dutch built, and to all appearance brawny enough to perform the office put upon them, without flinching.

IV. If for no better one, it is for this last reason that I do not object to the use of Caryatides, as being disagreeable to the feelings. Thank heaven! my feelings are not quite so refined and super-refined as to be shocked at beholding ladies of stone, bearing a burden they seem quite able to support. I should as soon think of expressing my sympathy for the Cardinal Virtues which are frequently turned out of doors, and doomed to keep watch on the outside of a building in all weathers, while the Cardinal Vices, perhaps, are enjoying themselves very snugly within.—As soon should I think of being mawkishy sentimental, and compassionating some poor devil of a Neptune who is compelled to stand as a sentinel on such a ticklish situation as the top of a pediment, to be there roasted in a broiling sun. It is wonderful how vastly sentimental many people can be, provided the display of outrageously fine feelings costs them nothing! Many a one who would almost pretend to snivel at "Patience on a monument smiling at grief," would drive over a poor old apple-woman and her stall, as unconcernedly as if she were a mere stock and stone. And yet the Apple-woman is a more perfect image of patience, than all the "Patiences" ever sculptured, were there one upon every hypocritical monument that has been erected.

V. Panegyric, as Swift observes, "is all pork, with very little variety of sauce: for there is no inventing terms of art, beyond our ideas; and when our ideas are exhausted, terms of art must be so too." This last remark certainly holds good, in regard to those writers and critics who repeat what they have picked up in praise of Palladio and Jones, pretty much as a parrot would repeat a pater-noster. They would fain insist upon our believing that those worthies possessed every architectural virtue and excellence; but to dwell upon their merits, or to examine the beauties of their edifices one by one, assigning to each its due value, is more than they care to attempt,—for reasons perhaps, well known to themselves, and not difficult to be divined by those who are not arrant gulls. Very quickly indeed are their ideas of art exhausted, for after they have uttered some stale commonplace, or vapid truism they are completely aground. It may be questioned whether "the celebrated Inigo Jones" would consider Goldicutt's publication of Heriot's Hospital, particularly complimentary, since the account of it is dispatched in less than a page and a half, without any thing being said in regard to the structure itself. Yet its beauties certainly require to be carefully pointed out, for they are of a kind quite invisible to unprejudiced eyes. Not so, however, the defects, they being glaring enough. The entrance tower might be supposed to have been intended as a whimsical burlesque on modern applications of the ancient orders; and the whole is no better than an architectural hotchpotch—an unintelligible, Babel-like jargon of styles jumbled up together. Still, for aught I can tell, the Doric entrance and Corinthian patchwork above it, may be precisely that part of the design which finds most admirers. The great charm after all, I suspect, lies in the name of Inigo Jones: take away that, and few persons would be able to discern any beauty or grandeur in it whatever.

VI. In the "Magasin Pittoresque" it is said that the windmill, built by him at Chesterton in Warwickshire, does Jones no less honour than the palace of *Blenheim*"! It is a wonder the writer did not favour us with the information that Inigo Jones was the father of the equally "celebrated" Tom Jones, of whom there is a tolerably well written life by one Mr. Henry Fielding, an author not very much inferior to some of the second-rate geniusses of our own enlightened age.

HISTORY OF DECORATIVE SCULPTURE IN FRANCE.

By Albert Lenoir, Architect.

(Translated for the Civil Engineer and Architect's Journal, from the Revue Generale de l'Architecture.)

GAULISH PERIOD.

In the earliest ages men, in however rude a condition, have always been fond of decorating their dwellings, an impulse to which the Celts and the Gauls gave way, and of which we find many evidences in their monuments. On the coasts of Britany, and on the sides of Druidic monuments, we see rude sculptures of rays and spirals so combined as to produce something of a decoration. On the well known peulvan or rough obelisk of Kervéatou in Finisterre, we find the head of a bull represented in such a way as to enable us to comprehend the outline. All other monuments which preceded the civilization of Gaul by the Greeks and Romans, except those of the Druids, having perished, we are deprived of the opportunity of describing the mode of ornamentation adopted by the Aborigines.

GREEK PERIOD.

The Phoceans, as is shown by the remains preserved in the Museum of Marseilles, brought into Gaul the elements of Asiatic art, which they used with taste. In 1773 M. Grosson, an inhabitant of that city, published a quarto volume,* in which are engravings of many ancient monuments, found within the boundaries of the old colony. Notwithstanding the mediocrity of the representations, we can easily recognize on some of the tombs, decorated with bas reliefs and inscriptions, how completely they had succeeded in imparting a classic taste, the crowns of olive leaves, and wreaths of flowers and foliage boast the same elegance as on the coasts of Attica or the Peloponnesus, Caria or Ionia. On the borders of the territory of the Greek colony, in a place called Le Bas Vernègues, near the Pont Royal, on the road from Aix to Lambesc, is to be seen a temple of the Corinthian order, evidently of a Greek character, both as regards its general composition and the style of its mouldings and ornaments, as may be judged by the following engraving.

Fig. 1—Leaves of the capital of Vernègues.

The capital of a grave form, notwithstanding the richness of its details, is decorated with sharp cut leaves, like those still to be seen at Athens, and on the coasts of Asia Minor. It reminds us of the foliage used in the decoration of the capitals of Pompeia, sculptured in the Hellenic school. In the temple of Vernègues, the bases of the columns, the mouldings of the pedestal, and the proportions of the architraves have evidently been designed and executed by Greeks.

The influence of the Asiatic colony was not limited to the bounds of the Marseillese territory, but was felt throughout Gaul, and thus it is we find at Vienne in Dauphiny, and at St. Remy-en-Provence, the ancient Glanum, traces of oriental art, as readily to be recognized there as in the fragments of the Phocean metropolis.

When Gaul came under the power of the Romans the Greek spirit still survived, as we may see in the case of the two cities just mentioned. At Vienne, the capitals of the temple of Augustus and Livia, were executed on the Greek plan, as may be ascertained by the finely executed sharp leaves, and in the Museum of Vienne, formed in the cella of the temple may be recognized more than one fragment which shows the Greek chisel.†

The tomb of St. Remy, raised for a Roman personage, as the inscription, figures and bas relief show, was also of Greek workmanship, this we can trace in the fragment of a capital represented in the following engraving, and further proved by the Greek contour of the mouldings.

Fig. 2—Leaves of the capital of St. Remy.

The capitals surmount the columns, decorating the upper part of the tomb; the sculpture of them is broad and well massed.

The triumphal arch at Orange is a monument cotemporary with the first victories of the Romans in southern Gaul, in it we trace something Greek, every detail serving to remind us, in some degree, of that school. The composition of the mouldings of the entablature, and particularly those at the top of the architrave bring to mind the profiles seen in the ancient edifices of Asia Minor; a cavetto is seen surmounting a line of ova, reposing on a string of pearls, a detail completely Ionian.* The modillions, decorating the principal cornice of the arch, have a remarkable peculiarity which is met with in the octagonal monument at Athens called the Tower of the Winds, and as we shall hereafter see reproduced in the Maison Carrée at Nimes, an edifice of a later date than that on which we are now treating. These modillions are sculptured in an inverse way from those which decorate all the ancient entablatures, the larger part, instead of resting against the cornice so as to form a console, is on the contrary near the outer edge of the corona, a very rational arrangement by the bye if we consider this part of the decoration as being derived from a wood building, and as the expression of the pendent extremities of the rafters, supporting the tiles. The resemblance between this entablature at Orange, and the Athenian edifice, which as it is described by Vitruvius,† must be of ancient date, comes in confirmation of the influence exercised by Greece on architecture and its details in southern Gaul. A specimen of the Greek palmetto is to be found in the midst of the foliage of the upper ogee of the impost of the Arch at Orange. The coffres, decorating the arches are executed with more delicacy than in any Italian monuments, particularly in the double arches, where we observe a happy arrangement which adds to the finish of the execution. In general, the Roman monuments of southern France show in their ornamentation a lightness of touch which may be attributed to the Greek school as introduced by the Phocean colony.

We have already shown what Hellenic elements are observable in the tomb of St. Remy; the same we have to notice in the triumphal arch of that town, particularly in the double arches decorated with arabesques. The archivolts of this monument, as well as those of the triumphal arch of Orange, are decorated with foliage and fruits, taken from the produce of the country, an interesting ornament as it makes us acquainted with the state of culture at that date.‡

ROMAN PERIOD.

Out of Provence we perceive a considerable change in the style of ancient architecture, approaching to the Roman forms, of which Nimes, one of the richest cities of Europe in antiquities, affords many examples, having been for a long time opulent enough to construct fine buildings. Augustus gave walls to Nimes, as is attested by an inscription on the gate, still bearing his name. The Corinthian capitals of the pilasters of this gate are executed with breadth, and remind us of the style at that period adopted at Rome. To the same emperor is attributed a portico which decorated the fountain of the Baths, the fragments of which are preserved on the site of the Temple of Diana. In the Maison Carrée are two of the finest bases ever sculptured by

† Vitruvius, book 1, chapter 6.

‡ See the introductory plates to the History of France, by Jorand, Jouffray and E. Brecon.

the ancients, also parts of the fountain.* At the temple of Diana are to be seen many fragments of richly ornamented double mouldings, which decorated the lower part of the great pedestal or stylobate in the centre of the Baths. They are beautifully executed. Neither must we omit the long marble frieze of the stylobate of the fountain preserved in the Maison Carrée.

The temple of Nîmes, known by the vulgar name of the Maison Carrée, and built in honour of the grandsons of Augustus, was executed by skilful artists; the capitals, in the Roman manner are broadly modelled, but we can see here, as well as on the frieze, abundant proofs of a difference in the skill of the several workmen employed. The modillions of this temple, as we have already mentioned, exhibit the same peculiarity as those on the Triumphal Arch at Orange, but being deeper cut, they are evidently imitations. The great gallery or colonnade around the temple, forming the sacred boundary, shows the same style of sculpture as the temple itself, but with less luxuriancy in the details: the frieze was formed of garlands, fruits and flowers, bound with floating ribands.

Antoninus, who was a native of Nîmes, adorned that city with many important buildings. To him are attributed a temple and a basilica dedicated to Plantina; and the fragments of sculpture collected in the Museum, apparently belonging to this golden age of art, fully bear out their claims. Among these may be remarked the eagles supporting the olive garlands; and a frieze composed of ox sculls, supporting garlands of fruit.

Vienne, the rich Museum of which is formed in the temple of Augustus and Livia, possesses more than one fragment of the best ages of Roman art.† Here are to be seen the cornice, frieze and architrave of a beautiful entablature, on the frieze of which is particularly to be remarked the rosette which serves to unite the bends of the foliage. The cornice is less remarkable, showing as it does in its modillions evident symptoms of the decline of the arts, first, because their form is that of a console en talon, little in harmony with the richness of the other members; second, because these modillions are all decorated differently, which is contrary to the strict rules of the best periods of art. It is singular that among all the remains of ancient art those of France alone should be found to present these departures from the general rule, an exception which we shall have occasion to remark both during the history of the Roman period, and of the middle ages, in which this variety of form became the parent of riches to a new style. In the Museum is also to be seen a beautiful piece of monumental sculpture, forming a frieze, and consisting principally of an eagle attacking a serpent. It seems to belong to the time of Septimus Severus.

Arles, a city of little importance before the time of Constantine, rapidly increased under the reign of that prince, and became to a certain extent, the Gallic Rome. Extensive buildings, still in existence, serve to show its splendour, but art was no longer what it was under the Antonines, the theatre, capitol, amphitheatre, and great cemetery or elyseum, show by the bad taste of their details, and the transposition of the principal members of the styles, how complete was the decadence. The capitol, of which a part is still to be seen in the Men's Square, consists of a ruin composed of two columns, crowned with an entablature and the fragment of a pediment; the ornamental sculpture is neglected, the frieze being composed of scrolls without character, while in the capitals, the bad proportions of the leaves indicate the period of ignorance at which the monument was erected. The theatre exhibits greater signs of decadence than even the capitol, the entablature of the lower story presenting the greatest anomalies, the sculptors have placed a frieze decorated with triglyphs and rosettes immediately above the capitals, where the architrave ought to be: then come a frieze in bad taste, and a badly proportioned cornice. In the Museum at Arles is preserved part of a marble entablature, which appears also to belong to the time of Constantine; the modillions varying every two and two in their decoration, which we have already pointed out as contrary to the principles of classic antiquity.

The walls of the city of Sens, of which the destruction, going on even now, presents numerous details of ancient architecture, placed by the Romans themselves on hasty foundations made in the time of the Emperor Julian, have afforded several cases analogous to those we have mentioned under the head of Arles.

The city of Autun, celebrated in Gaulish history and the capital of a province, has preserved some remarkable monuments. Those in the best condition are two gates attributed to Constantine, who was a great patron of the town. These two military constructions are in good style, both as regards the architecture and the ornamental sculpture, notwithstanding the well known general decadence of art which prevailed under the first Christian emperor. In the same city an ancient entablature of the Gallo-Roman epoch, which affords an example unique in France, of modillions sculptured on the angle of the corona. The ornamental details of this fragment show one of the last periods of Roman art in Gaul; we can however recognize the fertile imagination of the native artists, in the variety of *motives* in the sculpture, which change the form and character of each modillion.

A triumphal arch of large proportions is formed in the walls of the city of Rheims, and is now known as the Gate of Mars. The construction has been attributed to Cæsar by some modern writers, although there is nothing to give any foundation to this notion. An examination of the sculptural details of this edifice is enough to prevent its being assigned to any period anterior to the Lower Empire, and perhaps it ought rightly to be placed in the time of the emperor Julian, who fought often enough in the East of Gaul to obtain triumphal honours in a provincial city. In this monument the sculpture is of most uncommon barbarism, the foliage being scarcely of a recognizable form; the capitals out of proportion surmount heavy and badly chiselled columns, and the mouldings of disagreeable figure are made heavier by ornaments of which the model is a large hole in the midst of a shapeless leaf.

HISTORICAL SKETCH ON THE USE OF BRONZE IN WORKS OF ART.

By Cæsar Daly, Architect.

(Translated for the Civil Engineer and Architect's Journal, from the Revue Generale de l'Architecture.)

(Continued from page 219.)

The exertions of the Italian artists excited general emulation throughout Europe; and in a very short time every country used bronze for the decoration of its public edifices, and to transmit to posterity the deeds of its kings and great captains. Italy erected statues to the Medici and the Farnese, Spain to Philip III, Russia to Peter the Great, Sweden to Gustavus Adolphus, and England to Charles 1st. Much might be said with regard to the progress of this art, but we consider ourselves obliged on account of the extent of the subject to limit it to the history of bronze in France.

It was under Louis 14th, that this art made rapid progress through the enlightened endeavours of the two brothers Keller, whose principal master pieces are yet to be seen adorning the royal palaces of Versailles and the Tuileries. In 1699, Balthazar Keller cast in one piece the equestrian statue of Louis 14th, modeled by Girardon. This colossal mass was more than seven yards high, and yet weighed only 26,072 kil. (57,50 lb.) It seemed however as if the art of founding had only attained this state of perfection soon to fall into decadence; the equestrian statue of Louis 15th, cast by Gor in one piece, from the model of Bouchardon, and afterwards raised on the Place de la Concorde, was only 5·40 m. (17 ft. 9 in.) in height, while its weight was 29,370 kil. (64,775 lb.) During the revolutionary crisis, the only bronze work was limited to cannon; but under the Empire, bronze was again appealed to, to take its place among the other arts in representing the military triumphs of the French. Unfortunately the art had been too long neglected to allow of success, and some of the first essays were not prosperous, the statue of Desaix was a complete failure, and the Column of the Place Vendôme is far from being a master-piece of founding.

According to M. Payen, to whom we are indebted for the following details, the execution of the Desaix statue was put up to contract, and it was undertaken for 100,000f. (£4,000), a price in which the bronze was not included. The contractor gave up his bargain to a bell-founder, and he knowing nothing of the fashioning of such great works, and calculating upon the basis of his ordinary limited operations, engaged to do it for 20,000f. (£800): but in order to economize as much as possible, he required that the sculptor should be forbidden from superintending the moulding. The most difficult hollows were filled up, in order to avoid the trouble they would occasion; an attempt was made to mould in sand with frames, furnaces were erected, and an ill-constructed scaffolding, and after many useless arrangements and expenses, the bronze was let out, and having burst the moulds, ran about. Thus the operation completely failed, a good deal of the bronze was lost, and it was necessary to begin again. The founder then tried to cast the monument in pieces, but not arranging his moulds well, nor securing a uniform mixture of the metal, the pieces produced were dissimilar. He managed however to fit them together, but all the proportions of the figure were altered, and as these defects could not be remedied by the chisel, a most wretched monument was produced.

When the Column in the Place Vendôme was erected, the same faults were repeated; a bargain was made with an ironfounder, who had never been engaged in bronze work, he however had the temerity to undertake the moulding and finishing at one franc per kilo. (9*d.* per 2 lb.) The government on the other side undertook to deliver to him in guns, taken from the Russians and Austrians during the campaign of 1805, the quantity of bronze necessary for the completion of this enormous monument. The founder used a furnace he had for casting iron, but not being aware of the phenomena of bronze casting, and urged by his vanity to attempt in the first instance the casting of several of the great pieces of the base of the column, he encountered several defeats. Each time he necessarily altered the alloy by oxidizing the tin, lead and zinc, which metals so oxidized passed into the scoriæ or were carried off by the current of warm air. He did not perceive this cause of continual loss, and continued to produce the bas reliefs; but it may be readily conceived that they contained more copper than the bronze of the guns. When the founder had got two thirds through the column, he found out that he had got no more metal, and being, according to contract, responsible for the metal delivered to him, he was at once ruined. In this lamentable situation he tried to melt up the white metal obtained from the reduction of the scoriæ, and a large quantity of refuse metal which he had bought up at a low price. The bas reliefs which he obtained from the mixture of all these materials were marked with blotches and lead spots, their colour from a dirty grey became quite black; the authorities refused to receive work so defective, and put his foundry under sequestration. He succeeded, after much petitioning, in obtaining a committee to examine his accounts, which was composed of two chemists, two architects, two mechanical engineers, and two founders, with an auditor of the Council of State for the chairman. The weight of each piece delivered by the founder was known; specimens were taken from them, and the proportional parts weighed, from which was made an ingot representing the mean composition of the whole column. It was then found by analysis that it contained:

Copper	89·410
Tin	7·200
Lead	3·313
Silver, zinc, iron	0·047
	100

The committee then took specimens of bronze from the guns remaining in the government stores, and an ingot was formed to represent as nearly as possible the mean composition. The analysis of this ingot gave the following proportions:

Copper	89·360
Tin	10·040
Lead	0·102
Silver, zinc, iron, loss	0·498
	100

It was further known, that the law in France had fixed the composition of gun metal at 90 parts of copper and 10 of tin per cwt., but that this law was never well executed, and during the revolution scarcely attended to at all; it was also known that these foreign guns were of a more complicated and baser alloy than the French. Taking all these circumstances into consideration the committee were of opinion that the founder had produced an alloy, if not superior, at least equal, to that which had been given to him; and that they considered that he could not be charged with fraud in his contract. The chemical operations further explained the whole proceeding; by making separate analyses of the specimens of the great bas reliefs, the shaft, and the capital, it was found that the first had only 0·06 alloy per quintal; the second, particularly towards the upper part, and the third contained as much as 0·21. It was therefore evident that the founder not knowing how to manage bronze, had refined his alloy by several times remelting, and consequently diminished the total weight, and that to make up for this loss, he was obliged to put into the last castings the white metal extracted from the scoriæ. Thus he had given bronze of too good alloy in the beginning, which had obliged him at last to make the alloy too low. The moulding of the several bas reliefs was so badly executed, that the chaser employed to go over them, removed by chiseling or filing, a weight of bronze equal to 70,000 kils. (7 tons), which were given to him, besides a sum of 300,000f. (£12,000) paid down.

It was certainly hard to pay so dearly for experience, but fortunately it was profitable; not however that all the subsequent bronze works in France have been more successful, for the founders had to submit to several severe checks, and were obliged to study the processes, and proportions necessary to form a good alloy. Thus when in 1817 Lemot was employed to cast the equestrian statue of Henry 4th, now on the Pont Neuf, he at least took the precaution to take specimens from three bronze statues of Keller at Versailles, which were the best, with regard to casting, green colour, and the grain. The following is the result of his analysis.

	No. 1.	2.	3.	Mean.
Copper	91·3	91·68	91·22	91·4
Tin	1·	2·32	1·78	1·7
Zinc	6·09	4·93	5·57	5·53
Lead	1·61	1·07	1·43	1·37
	100·	100·	100·	100·

Lemot thought that he had gained experience enough from these analyses, but he did not escape from serious difficulties during the casting. Wishing to make use of the furnace, which had been built for casting the equestrian statue of Louis 15th, formerly in the Place de la Concorde, but the furnace not having sufficient draught for the fusion of Keller's alloy, in which there was more copper than in that of the statue of Louis 15th, he was obliged after several trials to make great charges, and still the casting did not perfectly succeed. The body of the king had several hollows in it, and the belly of the horse failed, a hole so large having been formed that it was obliged to be filled up; further 14,000 kilo. (14 tons) of oxidized rubbish was sold off.

Casting in bronze, although presenting only slight difficulties in the manufacture of objects of small dimensions, has always required greater responsibility when it is required to form considerable masses, perfectly homogeneous. The component metals are deficient in energetic affinity for each other, when in fusion tend to separate in the order of their densities, and, when the less fusible begin to solidify, the others in a liquid state, rise up towards the top, where the easy oxidation of a component part of the alloy always causes the risk of refining the metal. Besides these great obstacles, others are encountered in calculating the several component parts of the bronze, where it is wished to obtain precisely the required quantity of metal for the object to be cast, also in the preparation of the model, the construction of the furnace, and the disposition of the moulds. These and other difficulties explain how many abortive attempts sometimes preceded in former days the casting of a large work in bronze. They point out why Falconnet was 15 years casting the equestrian statue of Peter the Great, which figures on an immense monolithic pedestal at St. Petersburg; why the Kellers were 9 years casting the statue of Louis 14th; why Bouchardon and his successor Pigalle took 8 years for that of Louis 15th, on the Place de la Concorde; why the statue of Desaix, and we may almost say the Column of the Place Vendôme, failed, and why the great equestrian statues we have mentioned did not come perfect out of their moulds. The statue of Peter the Great was obliged to be begun again from the knees of the Czar and the breast of the horse, to the top of the statue. Bouchardon had much trouble in restoring the delicate forms of the horse in his beautiful equestrian statue of Louis 15th, which were badly produced in the lower part, and we have related the difficulties encountered by Lemot and Piggiani in casting the statue of Henry the 4th, difficulties which lasted four years. We cannot better finish this essay than by mentioning those which have just been surmounted in casting the various parts of the July Column, and for the better effecting this we shall compare it with the Column of the Place Vendôme, which is the only one having any analogy to it. The Vendôme Column is only coated with bronze, and the largest pieces are only five yards in extent, while each of its tambours is composed of six pieces, and the whole cost of the column in specie and metal provided by the state was 2 millions (£80,000). The July column on the other hand is entirely of bronze, and each tambour is in one piece, the base of the column extends about 16 yards, and the capital at the most extended place has the enormous dimension of 26 metres, 85 feet. This column however only cost 1,172,000 francs (£46,880).

Inequalities in the thickness of the parts constitute one of the great difficulties of casting, because the thin parts cooling rapidly, and the thick parts slowly, the shrinking of the former taking place sooner than that of the latter is apt to split the metal. It may be also conceived that the shrinking of a large object is so much more than that of a small one, as its dimensions are greater, and the necessity for taking this into consideration causes a fresh difficulty in the construction of the mould, which must be calculated so as to provide for the contingency. It is easy in the same way to conceive that the least motion of the mould, during the operation, will cause the required thickness to be exceeded. These considerations will explain the difficulties which had to be surmounted in casting the several parts of the Column of July, and as to the statue we cannot do better than republish an extract from the report of M. Hericarb de Thury, made to the *Société d'Encouragement*, on the improvements introduced by M. Soyez in the moulding of bronze sculptures.

"This statue 4·25 m. (14 feet) in height, supported on the toe, and bending forward, presented great difficulties in the moulding, and still greater in the casting, as the solidity of the statue depended on the extreme lightness of the upper parts, and the strength of the leg on which it is supported. Had the old methods been resorted to, the figure would most probably have failed, or have been tried in several pieces; because the upper part being very thin would cool down immediately, while the lower part cooling more slowly, would have contracted on itself, leaving at the ancles an opening of about 25 millimetres (an inch), the metal contracting from 12 to 14 millimetres per metre (½ an inch) and the statue would undoubtedly have been lost. To obviate these difficulties, M. Soyez determined upon casting it head downwards, by which he diminished the danger, I say diminished, for in this posture, the mould must have yielded, or the leg broken above the ancle. To provide for this, M. Soyez placed on each side of the foot a branch of copper 6·6 met. (26 in.) broad, finishing in a strong head, so as to force the foot to contract on the knee. Further these branches were so managed as to be rather thinner than the leg. Full success crowned the trial of this bold and ingenious innovation, the casting of this admirable statue succeeded in every detail, being perhaps the first time that a figure of this importance was cast without any defect. The thickness of the statue is from 4 to 5 millimetres (a sixth to a fifth of an inch) in the upper part, except the wings, which are only 2 millimetres. The supporting leg is 55 millimetres (2¼ inches) thick, beginning from the ancle, and progressively diminishes in thickness up to the thigh."

The monument of July undoubtedly marks a new era in the history of the art of bronze casting, and places France in the first rank in its pursuit, and in order to do justice to M. Soyez, we must mention some of the improvements effected by him. This artist has got rid of the use of iron as a means of consolidating isolated parts of figures, and particularly in supporting members; he casts these parts full by turning the figure upside down, which is an important innovation. He gets over the resistance of the sand of the mould on the contraction of the metal, not only by the weight of the mould, but by the progressive tenacity of the bronze while cooling. This tenacity, which may be considered as proportional to the area of the section of the part so cast, is increased at pleasure by accessary parts placed in the mould according as they are wanted. It is thus that the Genius of Liberty was cast, having as it were a second shapeless leg placed parallel to that which supports the figure, and intended to become at the period of contraction, auxiliary to the statuary leg to which it was united by the two extremities. Thus also was cast the bent back leg of the horse of Charles Emmanuel of Savoy. In order to prevent this leg from breaking in the ham when cooling, the foot was united to the thigh by a strong tenon, which was afterwards chiselled away.

ENGINEERING WORKS OF THE ANCIENTS, No. 7.

WORKS OF HERCULES.

Besides the performance of the Egyptian Hercules already mentioned, Diodorus Siculus, Book 4th, gives an account of several works of the Greek Hercules. Not to speak of the operations attributed to him at the Straits of Gibraltar, there were two hydraulic works in Greece said to have been executed by him. The large champain country about Tempe being all over a stagnant lake, he cut trenches through the lower grounds, and through these trenches drained all the water out of the lake, by which means were reclaimed all the pleasant fields of Thessaly as far as the River Peneus. In Beotia he did quite the contrary, for to punish the Minyœ it is related that he caused a river to overflow the whole country, and turn it into a standing pool. In his passage of the Alps from Gaul, an expedition in which he was the predecessor of Hannibal and Napoleon, he levelled and opened the rough and difficult ways to make way for his army and carriages. In Italy Hercules performed some remarkable works about the Lake Avernus, for whereas the lake extended as far as the sea, Hercules is said by casting up earth, to have stopped up its current, and to have made the way near the sea, called the Herculean way.—In Sicily to express his good wishes for the inhabitants, he caused a pond or tank to be sunk near the city of the Agrineans, four furlongs in compass, which he called after his own name.—In Greece Hercules had the further merit of having diverted the River Achelous into another channel which he had dug for it. This irrigated a considerable part of the country, and was done to please the Calydonians. It gave rise to the poetical fable that Hercules fought with Achelous transformed into the shape of a bull, and in the conflict cut off one of his horns and gave it to the Etolians. This they call Amalthea's horn, in which the poets feign that there grows all manner of summer fruit, as grapes, apples, and such like, not the only time by the bye that engineers have filled the horn of plenty.

DEDALUS—ENGINEERING FESTIVALS.

Diodorus gives a long account of Dedalus, from which we have made the following extracts. Dedalus was an Athenian of the family of the Erechthidæ, being the son of Hymetion, son of Eupalamus, son of Erechtheus, King of Athens. He was extraordinarily ingenious, and very studious in the art of architecture, an excellent statuary and engraver upon stone, and improved those arts with many notable inventions. Dedalus was obliged to flee to Crete for the murder of his nephew Talus, who was killed by him out of envy. To Dedalus is attributed the invention of sails for ships. After leaving Crete he staid with Cocalus and the Sicilians, in whose country Diodorus, a native, says that works of his were to be seen in that day.

While on the subject of Dedalus we must not omit what the Biographie Universelle says on the subject of festivals established in his honour. When the Plateans returned to their native city, 311 B.C., after an exile of sixty years, they instituted an annual festival called Dedalia, which every sixtieth year was celebrated with extraordinary magnificence. All the trees cut down were made into statues called Dædala. The name of Dedalia was also given to a Theban fete in honour of the reconciliation effected between Jupiter and Juno by Cithero.

TALUS.

Talus is sometimes called Atalus, Calus, and Acalus; he was the nephew of Dedalus, as before mentioned, and murdered by him. Being the son of Dedalus's sister, and but a young boy, he was bred up with his uncle to learn his trade. Talus for ingenuity exceeded his uncle, and invented the potter's wheel; he got likewise a serpent's jaw bone, and with it sawed a little piece of wood asunder, then in imitation of the tooth in the jaw, he made the like in iron, and so he found out an instrument for sawing the greatest pieces of timber. He invented likewise the turner's lathe and many other tools.

PROMETHEUS—CRETAN HERCULES—VESTA—MINERVA—VULCAN.

Prometheus is according to some the first who stole fire from the gods, and bestowed it upon men (Book 5th), but the truth is he found out the way how to strike fire out of flint or stone. The Idæi Dactyli are also said to have found out the use of fire. They discovered the nature of iron and brass to the inhabitants of the Antisapterians, near the mountain Berecynthus, and taught the manner of working it, and because they were the first discoverers of many things of great use and advantage to mankind, they were adored and worshipped as gods. One of them they say was called Hercules, a person of great renown. After them were nine Curetes who invented swords and helmets.—Vesta invented the building of houses, and upon this account almost every body sets up her statue in their houses, and adores her with divine honours.—Minerva was the introducer of architecture, and also according to our chronicler of the use of garments, so that architecture and tailoring according to him boast one common parent. Vulcan they say found out the working of iron, brass, silver and gold, and all other metals that require forging by fire; and the general use of fire in all other cases was found out by him.

XERXES—AGRIGENTUM—PHEAX—THEMISTOCLES—DIVERSION OF THE NILE.

The Eleventh Book of Diodorus, is on Greek history, he mentions Xerxes throwing a bridge over the Hellespont, and cutting a canal through Mount Athos.

The Agrigentines in Sicily having acquired great spoil by the defeat of the Carthaginians, took the greater part of the prisoners into the public service, and employed them in cutting and hewing stone. They not only set them to build the largest of the temples, but made water courses and sewers underground, so great and wide, that though the work itself was contemptible, yet when done and seen was worthy of admiration. The overseer and master of the work was one Pheax, an excellent artificer, from whom these conduits were called Pheaces. The Agrigentines likewise formed a tank for fish, at great cost and expense, seven furlongs in compass, and twenty cubits deep. This by neglect of succeeding ages, filled up with mud, and at last through length of time turned wholly into dry ground; but the soil being very fat and rich, it was planted, and yielded the city a large revenue.

Themistocles has the merit of projecting and carrying into effect the construction of a haven at the Pyræus, by which the naval power of Athens was greatly increased. The account of his negociations with the assembly of the people is of much interest in an historical but not immediately relating to the end we have in view, we are compelled to omit it.

In the 21st chapter is mentioned the diversion of the Nile during the war between the Persians and Egyptians.

BLOCKING UP OF THE EURIPUS.

In his 13th Book our historian describes the measures taken by the inhabitants of Eubœa on their revolt from the Athenians. This island being separated from the continent only by the narrow strait of the Euripus, they solicited the Beotians to assist them in stopping it up, in order that they might receive assistance against any attacks from the Athenians who were masters of the sea. To this the Beotians agreed, and all the cities set upon the work, and every one strove with diligence to perfect it, all the citizens, foreigners and strangers being set to work. The mole began at Chalcis in Eubœa on one side, and at Aulis in Beotia on the other, that being the narrowest part. straits the sea was very boisterous and rough, but after this work muc more unquiet and raging, the passage being made so very straight and narrow, that only one ship could pass through. There were forts built on both sides upon the extremities of the moles, and wooden bridges made over the currents for communication.

Our author gives an account of several sieges by the Carthaginians in Sicily, who appear from his account to have been as skilful as the Greeks in military warfare. At the siege of Himera in Sicily, Hannibal the elder (Book 13th), undermined the walls, supporting them with great pieces of timber, which being set a-fire, a great part of the walls suddenly fell down.

In the 20th Book, in the account of the expedition of Agathocles into Africa, there is a description which mentions, the country as well irrigated and supplied with canals and sluices.

MACEDONIAN GOLD MINES.

Philip, King of Macedon, (Book 16th), having taken Crenidas, and called it Philippi, so improved the gold mines in those parts, which before were but inconsiderable and obscure, that by building of houses for the works he advanced them to bring in a yearly revenue of above a thousand talents.

The siege of Tyre by Alexander the Great, recounted in the 16th Book, required the execution of works on a very great scale. Alexander demolished Old Tyre, as it was then called, and with the stones carried by many thousands of men, raised a mole two hundred feet in breadth across the sea, which by the help of the inhabitants of the neighbouring cities, who were impressed for the purpose, was speedily carried out a considerable way. This mole was afterwards injured by a violent storm, when Alexander caused it to be repaired with trees laden with earth, and so again brought it near the city. By this and many other operations he was able to take the city, after a gallant defence, in which the inhabitants displayed much ability.

In the memorandum books of Alexander examined after his death, (Book 18th), were found heads of six colossal plans, among which were the following,—that a plain and easy road should be made straight along the sea coast of Africa to the Pillars of Hercules, that six magnificent temples should be built, and that arsenals and ports should be made in places convenient for the great navy he contemplated. things, although highly approved by the Macedonians, yet because they seemed things beyond all measure impracticable, were desired to be laid aside.

During the Seleucian war, (Book 19th), the Macedonians under Eumenes encamped on the banks of the Tigris, about three hundred furlongs from Babylon, Seleucus occupying the river with a flotilla of small vessels. The Seleucians, having sailed to an old water course, cut down the banks at a part where it had been filled up from length of time, upon this the Macedonian camp was surrounded with water, and all the tract of ground overflowed, so that the army was in great danger of being utterly lost. At last removing a great part of his army in flat bottom boats, he caused all the Macedonians to repass the river, and then for the purpose of recovering his carriages and baggage, by the direction of one of the native inhabitants, he set about cleansing such another like place, by which the water might be easily diverted, and the ground all round about drained dry. When Seleucus perceived this he granted a truce, and the works were suspended.

In the same book is the account of the natural inundation, by which the city of Rhodes was so much injured. Rhodes being built in the form of a theatre, and the rain very heavy, the water ran for the part into one place, and the lower parts of the city were presently filled with water, for the winter being looked upon as over, no care had been taken to cleanse the channels and sewers, and the pipes likewise in the walls were choked up, so that the water stood several feet deep, until part of the city wall breaking down, the pressure was suddenly relieved.

PILEWORK.

In a mention of the Cimmerian Bosphorus in Book 20th, it is related that the king's palace was surrounded with the river Thasis, and that there was a road to it through the fens, guarded with forts and towers of timber, raised upon pillars over the water.

DEMETRIUS POLIORCETES.

We find in the 20th Book a long account of the siege of Rhodes by the celebrated Demetrius, who among other works made extensive mines under the city walls, which being told to the Rhodians, by a deserter, the Rhodians made a deep trench along the walls, which was now ready to be tumbled down, and forthwith fell to countermining, and at length met the enemy under ground, and so prevented the mine from proceeding any farther.

MR. MUSHET'S PAPERS ON IRON AND STEEL.—No. 3.

Sir—The opinions adopted by Drs. Ure and Karsten respecting the quantity of carbon in iron, namely, assigning to white cast iron a larger proportion than to gray, and taking the manifestation of the graphite fracture in the latter as a certain sign that the quantity of carbon in the metal is on the decrease, appear to me so much at variance with, and subversive of, all that practical men have understood and believed upon this subject, that it is my intention, with your permission, to make a few remarks upon the matter, in order to ascertain, by an examination of facts, how far they are borne out by the appearances which we every day see exhibited on the scale of manufacture, and in the manipulation of the metallurgical department of the laboratory.

I hope your readers will not consider I have travelled out of my way to make any gratuitous observations on Dr. Ure's most elaborate work further than the necessity of the case required, seeing his views of the subject are at direct variance with my table of the proportions of charcoal used in the fusion, and in forming the various qualities of iron and steel so frequently referred to in these letters.

As a prelude to the subject, and with a view to enable your readers to arrive at a more clear understanding of the points at issue, I shall define and class the distinct characteristics which cast iron Nothing can be more marked in the page of metallurgy than those divisions in the progressive stages of this metal:

1st. Steel-grained cast-iron, or crude steel.
2nd. White cast iron.
3rd. Gray cast iron.

In the absence of chemical analyses, but grounded upon numerous direct and comparative experiments, I have considered steel-grained cast iron to contain from 1 to 1½ per cent., the white cast iron from 1½ to 2½ per cent., and gray cast iron from 2½ to 4, or, when richly carburetted, to 4½ or 5 per cent.

Steel-grained cast iron is rarely to be met with at the blast furnaces in this country: decided traces of it are occasionally to be found in the commencement of a blast, particularly should the furnace be started with too heavy a charge; a high temperature being required to maintain its fluidity, it either sets on the bottom of the furnace, to be cleared off afterwards by an alloy of gray iron, or it escapes with the white iron when the furnace is tapped. At this juncture, which, when steel-grained iron is produced, is always one of difficulty in the affairs of the furnace, should the iron which has been obtained be examined, it will be found possessed of a white fracture, frequently mixed with a portion of the steel-grained iron.

Calcareous ores, however, afford the steel-grained cast iron more as a natural product; the supposed alloy of the metal of lime with the iron produced from those ores, renders the white cast iron more lively and fluid than the gray, and becomes in some measure a substitute for carbon in maintaining a considerable degree of fluidity, when the metal is at any time passing into the steel-grained quality, so as it may be run out of the furnace in quantity, and with a comparatively clean cinder.

Castings made of such iron possess a degree of strength quite unknown in the general operations of the foundry; they will beat up like soft steel, and acquire by hammering a permanent flexure like malleable iron; but, as far as my information and experience g attempts hitherto to remelt it have failed.

as this peculiar state of the metal

maker of this country, yet the whole of his metallic produce, in passing through the furnace, must have, in the first instance, been subjected to this process of steelification, before it absorbed enough of carbon to constitute it white cast iron. It may, however, be produced at any time artificially, by exposing white cast iron, particularly of that quality that merges on the steel-grained, in an open or covered furnace for some time to the action of a red heat, the time of exposure to be commensurate to the thickness of the iron employed. This operation has the effect of discharging the white or lamellar fracture, and substituting in its place one of a grayish colour, very dense, and minutely steel-grained, the process itself being one of decarbonization, and which, from its colour and softness under the file, ought not to be taken, as it sometimes is, for a manifestation of an increased quantity of carbon in the iron.

2ndly, as white cast iron occupies a position between steel-grained and graphite or gray iron, and is frequently found merging in both, it of course possesses a variety of quality and character greater than either of the other two, so as to render the details of experiments made with this variety of the metal subject to greater uncertainty than with the graphite or steel-grained.

Dr. Ure has assigned no definite quantity of carbon to the steel-grained iron, but that, in his estimation, it possesses a notable proportion, may be gathered from what follows: he assigns to white cast iron a maximum dose of $5\frac{1}{4}$ per cent., and further states that with a proportion of $4\frac{1}{2}$ per cent. it still retains its white or lamellar fracture. So that in the absence of more correct data, it may be inferred that when the change to steel-grained iron has taken place, the iron has lost 1 per cent. and still retains about $3\frac{1}{2}$ per cent. of carbon, so that as it regards carbon, the iron is in the same situation with good foundry iron, but observe the difference when this theory is tested by practice—the foundry iron will melt in an air furnace, and come out as fluid as water, while the steel-grained iron, under the same circumstances would not melt at all, but pass rapidly into the state of malleable iron.

3rdly, graphite or gray cast iron first makes its appearance by small dark specks inserted on the fracture of the white iron, and at this stage it is said to be mottled when those specks cover the entire surface, and receive, from the addition of more carbon, some degree of lustre, the iron is said to be bright gray; as the fracture becomes more open, and the colour darker, it is called dark gray iron; and when uniformly open throughout with a smooth surface, it is called best foundry iron.

Hitherto it had been supposed and believed that white cast iron contained a much less quantity of carbon—that the change of fracture from white to gray was in consequence of the iron absorbing or becoming united with a large share of that substance—that whatever carbon white iron contained, the graphite was so much in addition, and never considered as a symptom of its abatement.

Dr. Ure, however, holds a contrary opinion; according to him, the greatest quantity of carbon which can be united to the metal is in the state of white iron, and may be to the extent of $5\frac{1}{4}$ per cent, as the iron becomes more gray by the addition of carbonaceous matter in the furnace, the quantity of carbon in it diminishes inversely to $3\frac{1}{2}$ or 4 per cent. This I confess is a paradox of difficult solution, as it involves, to a certain extent, the operation of substracting during a process of repeated additions.

Independent of this, the new theory is to me abundantly perplexing, as the student has to deal with carbon in a considerable variety of states with which he had not been formerly familiar. We have "free carbon, residuum of plumbago and carbon, graphite or plumbago, combined carbon, carbon unaltered, carbon in mechanical mixture, carbon in a state of alteration, &c." The most of this is new and strange to me, but I may inquire whether Dr. Ure ever separated carbon from cast iron by mechanical means that were not magnetic.

Were the new theory true, we should be obliged to abandon the old legitimate conclusion that iron and steel were fusible in proportion to the carbon they contained, but now inversely, seeing white pig iron, which is said to contain the most carbon, is much more infusible than gray iron.

The process of refining pig iron for the manufacture of bar iron, would, under Dr. Ure's system, be no longer a decarbonating operation, but the reverse; for when the gray pig iron introduced into the furnace, had acquired the white or lamellar fracture, it would be found to have absorbed or taken up $1\frac{88}{100}$ of carbon in addition, being the difference between $3\frac{1}{4}$, the utmost that forge iron may be supposed to contain, and $5\frac{1}{4}$, the quantity assigned to white iron, and this during an operation of the most severe decarbonization with which we are acquainted.

In like manner, suppose a founder was to charge his air-furnace with 2000 lb. or any other quantity of gray pig iron, which is known to contain $5\frac{1}{4}$ per cent. of carbon by repeated fusions, accompanied with a considerable loss of iron, it would at last become possessed of the white or lamellar fracture, and have acquired nearly 2 per cent. more of carbon while passing through a repetition of consecutive fusions. To believe this for one moment appears to me the climax of absurdity.

Again, in the blast furnace a comparatively limited quantity of coke only is necessary merely to fuse the charge, and cause the whole to flow in one common slag, without any portion of the iron being separated. More coke, that is carbon, is added, separation takes place, the iron becomes white, and partakes of the lammelated fracture, and may at that period be supposed to contain the maximum dose of $5\frac{1}{4}$ per cent. of carbon. The manufacturer, aiming at a more profitable result, adds more and more carbon in the furnace, until he has attained his object as to quality; but, according to the new doctrine, while he has been adding carbon in the furnace, it has been uniformly diminishing in the pig iron.

The pig iron maker might naturally put the following questions: if white pig iron absorbs $5\frac{1}{4}$ per cent. of the fuel by weight, how is it that this augmentation is not felt in the yield of our ores, but quite the contrary, whereas, when the furnace is making gray iron, the yield from our ores is considerably better?

The operator in the laboratory may be apt to doubt and inquire how it is that, after obtaining his metallic result in white cast iron, and with a fine gloss, he can at any time, by the addition of charcoal, augment the produce of his ore from 1 to 3 per cent. This fact has been known and acted upon by myself for at least 40 years, so that when carburetted results have been obtained beyond the range of the blast furnace, an allowance has been made in the yield of the ore for their extra dose of carbon.

The steel iron maker of Hindostan might well call in question the truth of the new theory upon the most solid and philosophic grounds; for were it so that white cast iron contained more carbon than gray iron, he would decidedly make white iron in preference, for he could do it for for one third of its present cost for charcoal; but he has continued for ages to make gray iron, for the best of all reasons, viz., that his customers can, with gray iron, convert into steel a greater quantity of malleable iron than they can with white.*

On the same grounds I make no doubt that Agricola understood the secret of making iron like the East Indian (gray cast iron), for the purpose of converting, by steeping therein his malleable iron, into steel, and on the same principle, namely, that of its possessing more carbon to communicate to the iron.

I shall, for the present, furnish no further objection to the theory of Drs. Ure and Karsten, but conclude by stating the following facts as being finally conclusive against it:—quantities of gray cast iron, white cast iron, and steel-grained cast iron, were reduced to powder so small as to pass a sieve containing 900 holes in the square inch of its surface, my purpose being to form a species of metallic charcoal to be used in the reduction of an ore of iron, confident that that iron which contained the greatest proportion of carbon would revive from the ore the greatest per centage of iron. A micaceous ore was used in preference, from its presenting more surface to the iron, and which contained 70 per cent. of iron: with the powder made from gray iron 40 per cent. was on the average obtained from the ore, besides making good the weight of the original quantity of iron introduced into the crucible, whereas, when the same experiment was carried into effect with the white and steel-grained iron, not only was there no yield obtained from the ore, but the original iron had sustained a loss varying from 4 to 8 per cent.

I will now make a few final remarks upon the subject of the alleged quantity of carbon contained in steel, on which subject I find my opinions as widely different from those of Drs. Karsten and Ure as upon the proportion which they allege is contained in white cast iron, and which has been alluded to at large in my former communications on this subject.

Dr. Karsten, whom Dr. Ure quotes upon most occasions on the subject of iron and steel, says that he has found the proportions of carbon in steel vary from $1\frac{1}{4}$ to $2\frac{3}{4}$ per cent.; now in noticing this latter proportion, I have no hesitation in saying that $2\frac{3}{4}$ per cent. of carbon united with iron would not form steel at all, but white cast iron. Again, it is said that the proportion in blistered steel reaches, sometimes, but never exceeds, $1\frac{3}{4}$ per cent., so that we are led to infer that some sort of steels contains 1 per cent. more carbon than that which is said to be contained in steel of cementation. According to my knowledge and view of the matter, steel of any sort united with $1\frac{3}{4}$ per cent. of carbon, would not at any degree of heat extend under the hammer, or be applied to any useful purpose. $1\frac{3}{4}$ per cent. would be

* See my Papers on Iron and Steel, page 670.

nearly equal to $\frac{1}{37}$ part the weight of the iron; now $\frac{1}{96}$ part the weight of iron of charcoal fused with Swedish charcoal bar iron on the scale of manufacture, affords cast steel of a very high quality, which requires careful working at a low red heat to convert it into form; any increase of charcoal beyond this proportion would entirely destroy its ductility, either cold or hot. Should an adequate allowance be made for the waste which the charcoal must unavoidably undergo in the crucible, before the affinity is established between it and the bar iron, and for the moisture which, in common with all charcoal, it contains, probably not more than $\frac{1}{3}$ of its weight becomes united to the iron in the process of fusion.

In proof that Dr. Karsten's estimate of the proportions of carbon forming steel is excessive, I refer to the celebrated Bergman's analysis of Swedish steel iron and steel. According to him, the proportion of

carbon in steel is (or $\frac{1}{200}$ part) - -	·50
Carbon originally in the iron -	·12
Taken up by the iron in passing into the state of steel, equal $\frac{1}{263}$ part; a proportion very different from those furnished by Dr. Karsten, which range from $\frac{1}{38}$ to $\frac{1}{65}$ - -	·38

A still less proportion of carbon was found in the laborious analyses of four specimens of French steel iron performed by M. Vauquelin, and which seems to have carried the dose of carbon to the opposite extreme.

*Specimen No. 1,	contained of carbon	- -	·110789
Do.	2	do. - -	·00683
Do.	3	do. - -	·00789
Do.	4	do. - -	·00643

I also subjoin a very accurate and interesting analysis made by Mr. Tennant at Glasgow, and inserted in the 6th volume of the transactions of the British Association, of cast steel made from Danamora iron, which, in point of proportion, coincides with my view of the matter:

Iron - - - - - -	99·288
Manganese - - - - -	·190
Carbon - - - - - -	·388
Loss - - - - - -	·134
	100· parts.

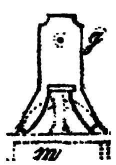
This proportion is equal to $\frac{1}{258}$ part the weight of the steel, and exhibits in a most striking point of view, the minute proportion of carbon which communicates to iron the varied and enduring properties of steel, without which, or some equally powerful substitute, arts and manufactures would soon become stationary.

Your's, &c.,

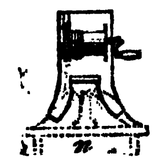
Coleford, June 17. D. Mushet.

P.S. When Dr. Ure revises the article upon the assay of iron ores, I should recommend him to substitute some other glass or flux for flint glass, as it would be inconvenient and perplexing for the juvenile assayist to have to deal with a button of iron over-riding one of lead, the former containing a little lead, and the latter some iron.

PLATE LAYERS GAUGE LINE.



f, four lengths of 16 feet rails, with the set-ups at *o* and *p*.
o, *p*, the set-ups on the rail with the line fixed, and showing the reel at *p*.
g, *b*, ditto across the ditto.
m, *n*, section of chairs and rail, with the instrument placed.
r, *r*, *r*, top of rail when corrected.



Sir—I take the liberty of handing to you the annexed rough sketch of a plate-layer's line, &c., for the purpose of enabling the plate-layer to keep nearly a correct gradient on the surface of the rails, between two correct heights, at the distance of four or five 16 feet rails. If you think this of any use, or worthy of insertion in your widely circulated Journal, it is at your service, at the same time I beg to say that I am not aware of its ever being applied, but from the best consideration I am able to give on its utility, I am persuaded that it may be applied to advantage, more particularly on railways like the Great North of England, which has so many favourable positions for a great distance in a straight line.

The instrument can be made very portable, and of a light construction, readily fixed on the cheeks of the joint chairs, at any distance required, by merely placing the claws of each set-up on them, no other fastening being required.

One of the set-ups (or gauge) is furnished with a reel and ratch, so that when the line is wound tight, it will be kept from slacking; the line must be made fast to the other 'set-up,' and at equal distance ... rail with the other. When the points at *a* and *e*, (sketch *f*) are connected, the instrument may be then fixed on these places; when the intermediate blocks, &c., at *b*, *c*, and *d*, may be beat up to the proper height, by gauging from the line to the top of rail, (as per dotted line at *f*, *r*;) the line may be so arranged as to stretch from the points *a* and *e*, on the surface of the rail, and the intermediate rails then brought up to the line, so that no gauging would be required, but I believe the first process would answer the best.

Your obedient servant,

M. Q.

York, June 13, 1841.

If you refer to page 184, I wish you to correct an error in the weight of chairs, &c., the following is the correct statement, and should have been inserted:—

Joint chair - -	40 lb. each.
Middle - -	30
Check - -	41

M. Q.

CHIMNEY FLUES.

Sir—According to the new Act, chimney flues are, in future, not to be less than 14 inches by 9 inches, or (if cylindrical,) 12 inches diameter. Is this meant to apply to the whole extent of the flue? for if so, all chimney-pots, &c., of less diameter are at once condemned; as far as such unsightly terminations are concerned, that will however be no loss; but as experience has proved that when flues exceed a certain size, contraction becomes necessary, at the top at least, to ensure a good draught, if that is henceforth not to be permitted, the fire-places, in order to contain fire enough to rarify the greater column of air that will thus be exposed to its influence, must be enlarged to an inconvenient extent.

Your opinion on the proper construction of the Act, will oblige your obedient servant,

A Subscriber.

N.B. According to Tredgold on this subject, flues seldom ought to be more than 8 or 9 inches in diameter, indeed frequently much less; and when climbing boys are no longer permitted, there can be no objection whatever to making them of any size that the particular case may require; and indeed there never was any objection, since there is no necessity, even now, for using so barbarous a mode of sweeping as is about to be forbidden by law.

[We are of opinion that the Act does not apply to chimney; a chimney-pot is not a flue—the flue terminates with the brick. Editor.]

* See Mushet on Iron and Steel, and the quarto edition of Nicholson's Journal.

ON THE BUILDING MATERIALS OF THE UNITED STATES OF NORTH AMERICA.

By David Stevenson, Civil Engineer, Edinburgh.

Read before the Society of Arts for Scotland in Session 1841.

There is, perhaps, nothing connected with the useful arts, which has a greater share in forming the characteristic appearance of a country, than the materials which it produces, and of which its public works are necessarily constructed. I use the word *materials* in the technical sense in which it is employed by engineers and architects, to denote the several productions of the mineral and vegetable kingdoms which are used in the construction of engineering and architectural works; and we have only to look around us for a moment, to be at once convinced how much these, in their almost endless variety, affect the appearance, as well as modify the structure, of the public works of every country.

A good illustration of the truth of this observation presents itself, when we compare the circumstances of Scotland and England in this respect; the former being what may be termed a *stone*, and the latter a *brick* country. To what circumstance can the far-famed beauty of the Scottish metropolis be more reasonably attributed, than to the great abundance of beautiful sandstone afforded by the quarries in its immediate vicinity, to which its street architecture and public buildings are so greatly indebted for their striking appearance. This remark applies, as we are well aware, not only to Edinburgh, but to many other towns in Scotland; while our less highly-favoured neighbours in the south, from the scarcity of good coloured building stone in some districts, and the total want of it in others, are reduced to the necessity of using brick for their dwelling-houses, and in many instances for their public buildings. So generally acknowledged are the fine qualities of the stone from many of the Scotch quarries, that it is exported to a considerable extent. To London itself, indeed, a large quantity of stone is annually sent from Craigleith in Mid-Lothian, which is the largest, and probably the finest sandstone quarry in the world, and of which the dwelling-houses in the New Town of Edinburgh, and most of the public buildings, were in a great measure built.

Many similar illustrations may be found, even in matters of much smaller importance than that to which I have just alluded. In Great Britain, for example, with the exception of some districts in England, the roofs of houses are very generally covered with slates, the greater part of which are supplied by the extensive slate quarries of Bangor in North Wales, and Easdale, Balachulish, and others, on the west coast of Scotland. But Holland has not the advantage of a like supply, and consequently the houses in that country are invariably covered with tiles; and if we extend our observations still further, to Canada and the United States, we there find that the want of more suitable materials for roofing, and the great quantities of fine timber with which those countries abound, have induced the inhabitants to cover their dwelling-houses with wood cut into thin pieces called "shingles," while the spires of the churches, which rise from all the principal towns on the banks of the St. Lawrence, are covered with highly polished tin.

Another of the many illustrations that may be given, appears in the construction of roads—a most important branch of engineering. The roads in this country are now invariably macadamized, as materials hard enough for forming them advantageously on that principle are very generally met with throughout the length and breadth of the island. In France, on the other hand, the want of hard materials renders Macadamizing not so applicable; and consequently, it has not by any means been generally introduced in that country, many of the principal roads being still *pitched* or paved with large stones. In Holland, owing to the scarcity of stones of every description, most of the roads are paved with small well-burned bricks, called "clinkers," which are set in sand, and present an exceedingly smooth surface; while in America and Russia, we find long stretches of "corduroy road," constructed entirely of timber—the produce of their extensive forests, which forms a species of highway by no means so well calculated as any of the others alluded to, for extending communication or promoting the comfort of the traveller; as the painful experience of every one who has travelled on them can abundantly testify.

The materials of every country may therefore be regarded as a subject of great interest connected with its history, and this consideration has induced me to offer a few remarks on the materials employed in the construction of the public works of the United States, in the belief that they may not be uninteresting to the members of a society which has for its object the promotion of the useful arts.

Iron is pretty abundant in North America, and it is worked in several parts of the United States. The only iron-works which I had an opportunity of visiting in the course of a late tour in that country, were those in the neighbourhood of Pittsburg, on the river Ohio, which are said to be the most extensive in America. At this place, the workmen were engaged in the manufacture of pig iron and plate-rails for railroads. The use of plate-rails, however, has been very limited, and as no other description of rail has been manufactured in the country, it has been the practice to import both the rails and chairs for the greater part of the American railroads from Britain, as well as the iron used for some other purposes. The government of the United States, indeed, in order to facilitate the progress of railways, do not exact the duty on iron rails and chairs imported from this country. It may safely be said, that the manufacture of iron in the United States, and what is more closely connected with the subject of this paper, its application to engineering works, are still in their infancy, at least when we regard the great extent and perfection to which these arts have been brought in Britain; and my observations on the materials of the country will therefore be confined to those of masonry and carpentry, as these are in some degree peculiar to the country, and any remarks regarding them will of course be more interesting.

Brick is the building material which is now invariably used in the construction of dwelling-houses in the towns of the United States. Timber is still pretty generally used for houses in the country; but of late years the erection of wooden structures, from their liability to take fire, has been prohibited in the neighbourhood of towns. Clay suitable for brick-making is found in great quantities, which is a fortunate circumstance for the inhabitants; and the bricks, which are burned with wood, and manufactured in other respects like those in this country, generally cost about 6½ dollars or 26s. a thousand.

Experience in our own and in many other countries, has proved that brick is well suited for house-building; but experience has also shown that it is by no means so well adapted as stone for engineering operations generally; and to some works it is with us considered wholly inapplicable. Marble and granite, of which I shall afterwards have occasion more particularly to speak, occur in the northern parts of the United States; but stone easily accessible to the quarrier, and fitted for building purposes, is very rarely to be met with, and the American engineers have therefore been obliged, as is the case in all countries, to adapt the structure of the works to the materials they possess; and in making this adaptation, they appear to have violated many of the established rules of engineering as practised in this country. The scarcity of stone, and the unsuitableness of brick for hydraulic purposes, for example, has forced them to construct most of the locks and aqueducts on the lines of their great canals wholly of timber, with which the country abounds; and that material, ill adapted as it may seem to such a purpose and situation, where it is not only exposed to the constant tear and wear occasioned by the lockage of vessels, but also to the destructive effects of alternate immersion in water and exposure to the atmosphere, has nevertheless been found in practice to form a very good substitute for the more durable materials used for such works in Europe.

Stone.—The quarries of the United States, taking into consideration the great extent of the country and the number of its public works, are, as I have already hinted, few in number; and, generally speaking, the workings are on a small scale. They afford granite and marble, and their produce is almost exclusively applied to facing public buildings, forming stairs, window and door lintels, and to other architectural purposes.

Granite is worked in the northern part of the country at Quincey in the state of Massachusetts, and at Singsing in the state of New York, and also in New Hampshire. The Quincey granite is of a fine gray colour, and can be quarried in large blocks. It has been used a good deal in Boston and the neighbouring country for architectural works. It has also been employed for railway blocks on some of the lines of railway in the neighbourhood of Boston, and in the construction of the only two graving docks which exist in the United States, the one at Boston, and the other at Norfolk in Virginia, the latter at a distance of upwards of 500 miles from the quarries; and these, so far as I am aware, are the only engineering works of any consequence in America in which granite has been employed.

The Singsing granite, which is of a dark gray or bluish colour, is quarried on the banks of the Hudson, about 25 miles from the town of New York, at which place it has been pretty generally used for some time for stairs and lintels, and has lately been introduced for facing buildings. The Astor hotel, the largest in America, and perhaps in the world, which is one of the very few stone buildings in New York, is built of this granite.

In the neighbourhood of Boston, and also Philadelphia, a species of soap-stone is found, which is quarried to some extent, and used in situations exposed to high temperatures instead of fire-brick.

MARBLE.—To the marble quarries, however, the Americans look for their principal supply of materials. These are more numerous, and are more widely distributed than the others I have mentioned, although they also are confined to the northern states. The principal marble quarries are in the states of Pennsylvania, Massachusetts, and Vermont. I visited some of them when in the country, and had also the advantage of receiving much information regarding them, as well as the materials of the United States generally, from Mr. Strickland, architect, at Philadelphia, and from Mr. John Struthers, marble-cutter, of the same place, to whom I am indebted for the specimens of marbles and woods which I had the pleasure of laying before the Society.*

The marble quarries in Pennsylvania are situate in the valley of the river Schuylkill, and are from thirteen to twenty miles distant from Philadelphia. They produce white, blue, black, and variegated marbles. Limestone is found resting on the marble, and is blasted off with gunpowder, and burned for making mortar. In some of the quarries which I visited, the beds of marble dipped from north to south at an inclination of 60° with the horizon, and they were worked at considerable disadvantage. In one quarry the men were working a bed of white marble 14 feet in thickness, at a depth of 120 feet below the natural surface of the ground. The blocks, some of which weighed 12 tons, were raised to the surface by means of a rudely-constructed horse-gin, there being no road to the bottom of the quarry, or rather pit, from which they are taken, by which even a man could conveniently, or safely, descend or ascend, without the use of a rope to prevent his falling headlong to the bottom. In this respect the American marble quarries reminded me of the celebrated sandstone pits of the ancient city of Caen in Normandy, which are not only remarkable as having produced the materials for the old London Bridge, but as presenting a mode of working very similar to that pursued in the coal-pits of this country; the blocks, being excavated at a great depth under the ground, are conveyed in subterranean passages to shafts, through which they are raised to the surface by horse power, as in the American quarries. The price of the American marble varies according to its quality and kind. The carriage of the materials, owing to the badness of the roads, forms a very expensive item in all the public works, and is, of course, regulated by the distance of transport; but the white marble costs about 4*s.* 10*d.*, and the blue about 4*s.* per cubic foot at the quarries, and although this may seem a very moderate price for marble, which in this country costs from 15*s.* to 2*l.* a cubic foot, still, when used instead of stone throughout the whole thickness of the wall of a dwelling-house, or the pier of a bridge, it becomes, even at the lower price I have mentioned, a costly material.

The Massachusetts quarries, which are at a place called Stockbridge, produce white and blue marbles, and the Vermont quarries, which are near Lake Champlain, furnish black and white marbles.

Those I have enumerated are the principal quarries in the United States; but from the circumstances of their being so much confined to particular localities, and the manner in which they are worked, it is evident that their produce cannot be applied by any means to the general wants of the country; and consequently, excepting in the case of buildings on which a good deal of money is to be expended, it is but little employed, the cost of the material itself, and the expense of carriage, being very considerable.

The marbles of the United States, according to the account of many intelligent Americans with whom I conversed on the subject, are not suited for sculpture or very fine ornamental works, or even, indeed, for the capitals of columns, which require superior workmanship; and the marble used for the capitals of all the fine buildings throughout the country is imported from Carara in Italy, whence a very large quantity is annually exported to America. For similar purposes black marble is also imported into the States from Ireland. If, however, I might form a judgment from the quality of some of the specimens which I procured, I should think that were the American quarries efficiently worked, there could be very little necessity for applying either to Italy or Ireland for so great an annual supply. Those buildings which are constructed of the whitest description of American marble carefully selected for the purpose, such as the Capitol and the President's house at Washington, the Bank of the United States, the Mint, and other public buildings at Philadelphia, and the monument erected to the memory of Washington at Baltimore, have certainly a most imposing and gorgeous appearance, owing to the fineness and beauty of the material. But the buildings which are constructed of the blue or unselected marble, such, for example, as the State Capitol at Albany, or the Town-House at New York, have a bloated and dingy look, and the general effect produced by the marbles in these buildings is greatly inferior to that of some of the sandstones from Craigleith and other British quarries.

The white marble retains its purity of colour much longer in the United States than it would do in this country, owing to the clearness of the atmosphere and the absence of smoke, the use of anthracite coal, which produces no smoke during combustion, being common in most of the towns. These circumstances may also account for the seemingly permanent vividness of the various colours, such as red, white, brown, yellow, and green, with which, according to the taste, or rather want of taste, of the occupiers, the exteriors of the brick houses in New York, and many other towns in the United States, are generally painted.

TIMBER.—I must now make haste to speak of the materials of carpentry, the other department regarding which I proposed to offer a few remarks.

The forests, to the British eye, are perhaps the most interesting features in the United States, and to them the Americans are indebted for the greater part of the materials of which their public works are constructed. These forests are understood to have originally extended, with little exception, from the sea-coast to the confines of the extensive prairies of the western states; but the effects of cultivation can now be traced as far as the foot of the Alleghany Mountains, the greater part of the land between them and the ocean having been cleared and brought into cultivation. It is much to be regretted that the early settlers, in clearing this country, were not directed by a systematic plan of operations, so as to have left some relics of the natural produce of the soil, which would have sheltered the fields and enlivened the face of the country, while at the same time they might, by cultivation, have been made to serve the more important object of promoting the growth of timber. Large tracts of country, however, which were formerly thickly covered with the finest timber, are now almost without a single shrub, every thing having fallen before the woodman's axe; and in this indiscriminate massacre there can be no doubt that many millions of noble trees have been left to rot, or, what is scarcely to be less regretted, have been consumed as firewood. This work of general destruction is still going forward in the western states, in which cultivation is gradually extending; and the formation of some laws regulating the clearing of land, and enforcing an obligation on every settler to save a quantity of timber, which might perhaps be made to bear a certain proportion to every acre of land which is cleared, is a subject which I should conceive to be not unworthy of the attention of the American Government, and one which is intimately connected with the future prosperity of the country. But should population and cultivation continue to increase in the same ratio, and the clearing of land be conducted in the same indiscriminate manner as hitherto, another hundred years may see the United States a *treeless* country. The same remarks apply, in some measure, to our own provinces of Upper and Lower Canada, in many parts of which the clearing of the land has shorn the country of its foliage, and nothing now remains but blackened and weather-beaten trunks.

The progress of population and agriculture, however, has not as yet been able entirely to change the natural appearance of the country. Many large forests and much valuable timber still remain both in Canada, and in the United States; the Alleghany Mountains, as well as other large tracts of country towards the north and west, which are yet uninhabited, being still covered with dense and unexplored forests.

The timber trade of the United States and of Canada, from the quantity of wood which is required for home consumption and exportation, is a source of employment and emolument to a great mass of the population. It is carried on to a greater or less extent on all American rivers, but the Mississippi and the St. Lawrence are more especially famous for it. The chief raftsmen, under whose direction the timber expeditions on these rivers are conducted, are generally persons of great intelligence, and often of considerable wealth. Sometimes these men, for the purpose of obtaining wood, purchase a piece of land, which they sell after it has been cleared; but more generally they purchase only the timber from the proprietors of the land on which it grows. The chief raftsman and his detachment of workmen repair to the forest about the month of November, and are occupied during the whole of the winter months in felling trees, dressing them into logs, and dragging them with teams of oxen on the hardened snow, with which the country is then covered, to the nearest stream. They live during this period in temporary wooden huts. About the middle of May, when the ice leaves the rivers, the logs of timber that have been prepared and hauled down during winter, are launched into the stream, and being formed into rafts, are floated to their destination. The rafts are furnished with masts and sails, and are steered by means of long oars, which project in front, as well as behind them; wooden houses are built on them for the accommodation of the crews and their families. I have several times, in the course of the trips

* These specimens are now in the museum of the Society of Arts.

which I made on the St. Lawrence, counted upwards of thirty men working the steering oars of the large rafts on that river, from which some idea may be formed of the number of their inhabitants. Those rafts are brought down the American rivers from distances varying from one hundred to twelve hundred miles, and six months are often occupied in making the passage. When it is at all possible, they moor them during the night in the still water at the edge of the river, but when this cannot be done, they continue their perilous voyage in the dark, exhibiting lights at each corner of the raft to warn vessels of their approach to them. The St. Lawrence rafts vary from 40,000 to 300,000 square feet, or from about one to no less than seven acres in surface, and some of them contain as much as £5000 worth of timber. If not managed with great skill, these unwieldy specimens of naval architecture are apt to go to pieces in descending the rapids, and it not unfrequently happens that the labour of one, and sometimes two seasons is in this way lost in a moment. An old and experienced raftsman, with whom I had some conversation on board of one of the St. Lawrence steamers, informed me that he, on one occasion, lost £2500 by one raft which grounded in descending a rapid and broke up. He said the safest size for a raft was from 40,000 to 50,000 square feet, or about one acre, and that five men were required to work a raft of that size.

The species of forest trees indigenous to different countries is an interesting subject connected with vegetable physiology. There are said to be about thirty forest trees indigenous to Great Britain, which attain the height of thirty feet; and in France there are about the same number. But according to the best authorities, there are no less than 140 species which attain a similar height indigenous to the United States.

To notice each of these numerous species, whose timber is employed by the Americans in the arts, even if I were able to do so, would greatly exceed the limits to which I am restricted by the nature of the present communication, and I shall therefore only make a few remarks regarding those timbers which are most highly prized and most extensively used in the ship carpentry and public works of the country.

The first which I shall notice is the Live Oak (*Quercus virens*), so named because it is an evergreen, its leaves lasting during several years and being partially renewed every spring. It grows only in the southern states, and is one of the most valuable of the American timbers. The duty imposed by our government on wood from the United States, prevents its importation into Britain, and as live oak grows only in the United States and is not found in Canada, it consequently never reaches this country as an article of commerce; the whole produce being consumed by the Americans themselves in ship-building. Its specific gravity is equal to, and in some cases greater than, that of water, and it is used along with white oak and cedar for the principal timbers of vessels. The climate, according to an American authority,* becomes mild enough for its growth near Norfolk in Virginia, though at that place it is less multiplied and less vigorous than in more southerly latitudes. From Norfolk it spreads along the coast for a distance of 1500 or 1800 miles, extending beyond the mouths of the Mississippi. The sea air seems essential to its existence, for it is rarely found in the forests upon the mainland, and never more than fifteen or twenty miles from the shore. It is most abundant, most fully developed, and of the best quality, about the bays and creeks and on the numerous fertile islands which lie scattered for several hundred miles along the coast. The live oak is generally forty or fifty feet in height, and from one to two feet in diameter, but it is sometimes much larger, and its trunk is often undivided for eighteen or twenty feet. There can be little doubt, from its great density and durability, that this is one of the finest species of oak that exists, surpassing even that for which Great Britain is so famous. Its cultivation has been tried in this country without success; but could it be imported, it would be found admirably suited for the construction of lock-gates and other engineering works, for which hard and durable timber is required, and for which English or African oak is generally used.

The White Oak (*Quercus alba*) is the species of which so much is imported into this country. It is known by the name of "American oak," but it is a very different and much inferior wood to the live oak of the United States which I have just described. It is also much more widely distributed, and occurs in much greater quantity, than the live oak. It is very common throughout the northern states and in Canada, from whence it is exported to this country. It attains an elevation of seventy or eighty feet, with a diameter of six or seven feet. It is known by the whiteness of its bark, from which it derives its name, and from a few of its leaves remaining on the branches in a withered state throughout the winter. The wood is of a reddish colour, and in that respect is very similar to English oak. But it is generally acknowledged to be greatly inferior to it in strength and durability. It is very straight in the fibre, however, and can be got in pieces of great length and considerable scantling—properties which, for certain purposes, make it preferable to the British oak. It is much used in ship-building, and also for the transverse sleepers of railways. There are many other oaks in the United States, but the two I have mentioned are those most in use.

The pines are perhaps the next woods in importance to the oaks. The species of those are also very numerous, and I shall only mention one or two of the most important of them.

The White, or Weymouth Pine (*Pinus strobus*), is widely distributed both in the United States and in Canada, and is exported to Britain in great quantities from the latter country. It is the tallest tree of the American forest, having been known, according to Michaux, to attain the height of 180 feet. The wood has not much strength, but it is free from knots, and is easily wrought. It is very extensively employed in the erection of bridges, particularly *frame* and *lattice* bridges, a construction peculiar to the United States, and very generally adopted in that country, which I have described in detail elsewhere.* For this purpose it is well fitted, on account of its lightness and rigidity, and also because it is found to be less apt to *warp or cast* on exposure to the atmosphere than most other timbers of the country. It is much used for the interior fittings of houses, and for the masts and spars of vessels.

The Yellow Pine (*Pinus mitis* or *variabilis*) occurs only in the southern and middle states, and is not found in Canada, and therefore does not reach this country, the wood known by that name in Britain being the *Pinus resinosa*. It attains the height of 50 or 60 feet, with a diameter of 2 or 3 feet, and is the timber which the Americans employ in greatest quantity for the masts, yards, booms, and bowsprits of their vessels. A large quantity of it is annually consumed for this purpose in the building-yards of New York, Philadelphia, and Baltimore.

The Red Pine (*Pinus resinosa*) is the only other of the pine species that is much used. It occurs in great plenty in the northern and middle states, and in Canada, from whence it is exported in great quantity to this country, and it is known to us by the name of "American yellow pine." It attains the height of 70 to 80 feet, with a diameter of two feet, and is remarkable for the uniform size of its trunk for two-thirds of its height. Its name is derived from the redness of its bark. The wood, owing to the resinous matter it contains, is heavy; and is highly esteemed for naval architecture, more especially for decks of vessels, both in this country and in America.

The Locust (*Robinia pseud-acacia*), from the beauty of its foliage and the excellent qualities of its timber, is justly held in great esteem in America. It abounds in the middle states, and in some situations attains the height of seventy feet, with a diameter of four feet. The wood of the locust tree is of a greenish yellow colour, marked with brown veins, not unlike the laburnum of this country. It is a close-grained, hard, and compact wood, and is of great strength. It is used, along with live oak and cedar, for the upper timbers of vessels, and is almost invariably used for treenails, to which it is well adapted. It is also employed in some parts of the country as transverse sleepers for railways. Its growth being chiefly confined to the United States, it is not imported into Britain, It is one of the very few trees that are planted by the Americans, and may be seen forming hedge-rows in the highly cultivated parts of Pennsylvania.

The Red Cedar (*Juniperus Virginiana*) is another valuable wood, the growth of which is confined to the United States. In situations where the soil is favourable it grows to the height of 40 or 50 feet, with a diameter of 12 or 18 inches. This wood is of a bright red colour; it is odorous, compact, fine-grained, and very light, and is used, as already stated, in ship-building, along with live oak and locust to compensate for their weight. It is considered one of the most durable woods of the United States, and being less affected by heat or moisture than almost any other, it is much employed for railway sleepers. I remember, in travelling on some of the railways, to have been most pleasantly regaled for miles together, with the aroma of the newly laid sleepers of this wood. It is now, however, becoming too scarce and valuable to be used for this purpose.

The White Cedar (*Cupressus thyoides*) and the Arbor Vitæ (*Thuja occidentalis*) are employed for sleepers and other purposes to which the red cedar is applied, but the latter is preferred when it can be obtained.

The only other tree which I shall notice is the Sugar Maple (*Acer saccharinum*) which occurs in great abundance in Canada and the

* The Sylva Americana, by J. D. Browne. Boston, 1832.

* Stevenson's Sketch of the Civil Engineering of North America. London: John Weale, 1838.

northern states. It attains the height of 50 or 60 feet, and is from 12 to 18 inches in diameter. The wood of this tree is soft, and when exposed to moisture it soon decays. It is very close-grained, and when cut in certain directions is remarkably beautiful, its fibres, owing to their peculiar arrangement, producing a surface variegated with undulations and spots. It is also susceptible of a very high polish. These qualities tend to render it a valuable acquisition to the list of American woods for ornamental purposes, for which it is very generally employed, and is well known in this country by the name of "Bird's Eye Maple." The wood of the Red-flowering Maple (*Acer rubrum*) is also employed for ornamental purposes, and is generally known by the name of "Curled Maple." The cabins of almost all American-built vessels are lined with these woods, or with mahogany inlaid with them, and they are also much used for making the finer parts of the furniture of houses.

The property of the sugar maple, however, from which it derives its name, is of perhaps more importance in a commercial point of view than its use as timber. I allude to its property of distilling a rich sap, from which sugar is largely manufactured throughout the United States. From two to four pounds of sugar can be extracted annually from each tree without hurting its growth. I had an opportunity of making some inquiries regarding this simple process when on the banks of the river Ohio, where I saw it in progress. One or two holes are bored with an augur, at the height of about two feet from the ground, and into them wooden tubes, formed of the branch of some soft-heaited tree hollowed out, are inserted. The sap oozing from the maple flows through the tubes, and is collected in troughs. It is then boiled until a syrup is formed of sufficient strength to become solid on cooling, when it is run into moulds and is ready for use.

Such is a brief notice of some of the principal timbers of the United States, which, from their great abundance and variety, are suitable for almost every purpose connected with the arts, and thus serve in some degree to compensate for the want of stone, while at the same time they afford great advantages for the prosecution of every branch of carpentry, an art which has been brought to great perfection in that country. Many ingenious constructions have been devised to render timber applicable to all the purposes of civil architecture, and in no branch of engineering is this more strikingly exemplified than in bridge-building. Excepting a few small rubble arches of inconsiderable span, there is not a stone bridge in the whole of the United States or Canada. But many wooden bridges have been constructed. Several of them, as is well known, are upwards of a mile and a quarter in length, and the celebrated Schuylkill Bridge at Philadelphia, which was burnt about two years ago, but was in existence when I visited the country, consisted of a single timber arch of no less than 320 feet span. Canal locks and aqueducts, weirs, quays, breakwaters, and all manner of engineering works have there been erected, in which wood is the material chiefly employed; so that if we characterize Scotland as a stone and England as a brick country, we may, notwithstanding its granite and marble, safely characterize the United States as a country of timber. I shall only, in conclusion, very briefly allude to the appearance of the American forests, of which so much has been written and said; and on this subject I may remark, that it is quite possible to travel a great distance without meeting with a single tree of very large dimensions; but the traveller, I think, cannot fail very soon to discover that the average size of the trees is far above what is to be met with in this country. I measured many trees, varying from 15 to 20 feet in circumference, and the largest which I had an opportunity of actually measuring was a Button-wood tree (*Platanus occidentalis*) on the banks of Lake Erie, which I found to be 21 feet in circumference. I saw many trees, however, in travelling through the American forests, which evidently far exceeded that size, and which my situation, as a passenger in a public conveyance, prevented me from measuring.

M. Michaux, who has written on the forest trees of America, in speaking of their great size, states, that on a small island in the Ohio, fifteen miles above the river Muskingum, there was a button-wood tree, which, at five feet from the ground, measured 40 ft. 4 in. in circumference. He mentions having met with a tree of the same species on the right bank of the Ohio, thirty-six miles above Marietta, whose base was swollen in an extraordinary manner; at four feet from the ground it measured 47 feet in circumference, giving a diameter of no less than 15 feet 8 inches; and another of nearly as great dimensions is mentioned by him as existing in Genessee; but these trees had perhaps been swollen to this enormous size from the effects of some disease. He also measured two trunks of white or Weymouth pine, on the river Kennebec, in a healthy state, one of which was 154 feet long and 54 inches in diameter, and the other was 142 feet long, and 44 inches in diameter, at three feet from the ground. M. Michaux also measured a white pine which was 6 feet in diameter, and had reached probably the greatest height attained by the species, its top being 180 feet from the ground. It is difficult for an inhabitant of our island, without having seen the American forests, to credit the statements which have been made by various authors, as to the existence of these gigantic trees of 180 feet in height (being about 40 feet higher than Melville's monument in St. Andrew Square, in Edinburgh); but such trees undoubtedly do exist. Mr. James Macnab of the Royal Botanic Garden, in a paper on the local distribution of different species of trees in the native forests of America,* mentions having measured numerous specimens of the *Pinus strobus* in Canada, which averaged 16 feet in circumference, and 160 feet in height; and one specimen which had been blown down, and of which the top had been broken off, measured 88 feet in length, and even at this height was 18 inches in diameter.

The ascent of the sap in trees is a subject which has long occupied the attention of physiologists. Some difference of opinion, however, exists regarding it, and hitherto it is believed no very definite conclusions have been arrived at;—and although not strictly connected with the subject of this paper, I may be excused for remarking, that the quantity of sap required to sustain such enormous trees as these I have been describing, and the source and nature of the power by which a supply of fluid is raised and kept up, at the great height of 180 feet from the ground, are inquiries which, could they be satisfactorily solved, would form most interesting and instructive additions to our knowledge regarding vegetable physiology.

Edinburgh, February, 1841.

ON THE SYSTEM OF WARMING BUILDINGS BY HOT WATER.

A Reply to Mr. Perkins's "Answer" (in the Journal for June last, p. 201,) to the Report presented to the Manchester Assurance Company. By John Davies, and George Vardon Ryder.

Mr. Perkins declaims against our "unfair report;" and charges us with "errors and misstatements," with "manifest absurdity," with "unjust and absurd experiments," "conducted with any view rather than that of candid investigation." Such charges are easily made on either side of a discussion, and are most generally resorted to by those who are least warranted in applying them. We shall presently show how unmerited and irrelevant such charges are in reference to us; and we trust that we shall be enabled to satisfy every disinterested reader, that Mr. Perkins has, in order to conceal the weakness of his defence, indulged his feelings in this kind of phraseology, which, from the facility with which he uses it, seems to be quite natural to him. It usually happens, as in this case, that the use of such language leaves every thing untainted but the reputation of him who utters it; while it forfeits every claim upon an opponent for any greater courtesy of expression in reply than the example would suggest, or the nature of the objections appear calculated to excite.

Our directions, as the reader of the preceding pamphlets will remember, were "to inquire into the *nature of the accidents which have* recently *occurred* from the use of the hot water apparatus; and to institute a personal investigation into some of the cases referred to; and to make such experiments as might tend to satisfy our minds as to the *causes* of the *accidents which had occurred*" from the use of the apparatus as it has been erected in Manchester, and *not* as it may have been since improved by the Patentee; for the latter being unknown until very "recently," that is to say, until our Report had appeared, it was impossible for us to notice.

We had to investigate the abuses, as well as the uses of the apparatus, as hitherto put up in this town and neighbourhood; for, if the abuses were likely to be of frequent, or even occasional occurrence, if they could arise from ordinary carelessness or mismanagement, it is clear that the danger to property must be very considerable. Of the advantages of Mr. Perkins's "recent" improvement we know nothing excepting what he tells us in his "Answer;" but, how ill soever he may think of us, we do most sincerely assure him, that if it really renders the apparatus secure, we shall hail its application with much pleasure; not altogether with a feeling of satisfaction, resulting from the consciousness that we have hastened, if not occasioned it, by having proved that it was necessary. From his own showing, therefore, Mr. Perkins ought, in this case, to be grateful, rather than angry. We have given to the apparatus a popularity which it did not previously possess, while we have pointed out its defects; these defects Mr. Perkins affirms that he has "recently" completely removed; and, therefore, the very detection of his former errors has tended to diffuse more widely a knowledge of his present state of perfection. Had an "opportunity" been "afforded" to Mr. Perkins "of assisting" us in our "experiments," it is far from probable that he would ever have obtained these advantages, of the source of which he so unreasonably complains.

It seems to be almost impossible to satisfy Mr. Perkins. At first he censures us because we attended to "appearances;" and he afterwards inveighs

---

* Agricultural Journal for 1835.

against us because we resorted to "experiments:" it is, therefore, difficult to conceive how we should have proceeded to form our Report, unless by an implicit reliance upon his assertions, which certainly do not, in some cases, rest upon either appearances or experiments.

The great gist of the charges against us is, that we employed in our experiments an apparatus improperly constructed; for he says, "the patentee *utterly disclaims the apparatus experimented upon* by Messrs. Davies and Ryder as his, any further than that the pipes were closed in all parts."—This charge assumes a very imposing aspect; and if we had done designedly that which he here imputes to us, we should indeed have been highly culpable. From a few facts the reader may judge of the truth of the allegation. Mr. Perkins sold some time ago to Mr. Walker the patent right to the apparatus for Manchester and the vicinity. When we were professionally engaged by the Directors of the Assurance Company, we first inspected the premises which had been recently injured; and then, previously to the performance of any experiments, applied to Mr. Walker to see what information or assistance he was able and willing to afford. Mr. Walker acceded, in the most obliging manner, to our application; accompanied us to some establishments where the apparatus was in operation; and promised to get erected on his own premises, and under his own superintendence, a suitable apparatus, on Mr. Perkins's system, for the express purpose of our experiments. Some little delay occurred; and, as it happened, Mr. Walker had in the interval several interviews on the subject with Mr. Perkins, to whom our investigation was no secret! The apparatus was at length put up; the form and the proportion of the parts were precisely those which Mr. Perkins had taught Mr. Walker, and on the same principle which had guided Mr. Walker in others which he had erected, and might be called upon to erect; and was, therefore, in every respect as essentially on "Perkins's System" as any of those which have been yet introduced into any building in Manchester. In short, Mr. Walker made the apparatus: we the experiments. In all the operations we had the assistance of Mr. Walker's intelligent Foreman, and that of other persons belonging to his establishment.

Mr. Perkins does not find fault with 26 feet of coil in the furnace, though he forgets that only 21 feet, as stated, were exposed to the fire, a fact which, being in his favour, he conveniently suppresses; but he seizes with avidity upon a presumed deficiency in the expansion pipe, insisting that from the proportions in the diagram annexed to the Report, it must have been "six inches less than the apparatus required." Now, even in this plausible objection a slight inadvertency on our parts has rendered him unfortunate; for the diagram having been originally drawn from dimensions given by one of Mr. Walker's assistants was, as it happened, six inches less than it was found, on actual admeasurement, to be in the apparatus really employed in the experiments performed.

It is asserted in the "Answer" that "in the *absence of Mr. Walker* a stopcock was introduced, which, cutting off the greater part of the circulation, left only 40 feet of the tubing out of the furnace to carry off all the heat that could be communicated from 26 feet within it." This is a grave charge; but like the others, it rests entirely upon Mr. Perkins's vivid imagination. A reference, however, to our diagram, which, by singular ill luck is, whether correct or incorrect, a stumbling-block to Mr. Perkins, will clearly show that instead of 40 feet of tubing there were 140, with 21 feet only exposed to the action of the fire! As to the stopcock, it is sufficient to remark that it was contrived and attached by Mr. Walker himself!

Mr. Perkins, in his allusions to his safety valve, places himself in an awkward dilemma. Such an addition is either necessary or it is not: if unnecessary, then it renders the apparatus no better than it was previously; but if it is really necessary, what are we to think of the person who has been until "recently" endangering, by his own acknowledgment, in his "some hundreds of apparatus," life and property to an unlimited extent? What are we to think of him who could, knowingly, leave such places as Messrs. Crafts and Stell's unsupplied with an essential protection? Did he carefully and promptly impress Mr. Walker with its great importance?

We have reason to believe that this gentleman was not acquainted with it previously to the publication of our Report. It appears, then, that Mr. Perkins sold for Manchester and the vicinity an apparatus which he has, for some time, known to be dangerous, and against which danger he did not warn either Mr. Walker or his customers until he produced his "Answer" to our statements. The public have, therefore, derived some information from our Report, whatever may be the advantage which the "Answer" has conferred upon its author.

Mr. Perkins rallies us very much for having said that the experiments made at the Natural History Museum, and at Messrs. Vernon and Co.'s, were "unsatisfactory." Whatever may be his opinion, we regard it as unwarrantable to make experiments, even with his apparatus, where other people's property might be endangered. That was, we can assure him, the reason which induced us to afford him this opportunity for the display of his pleasantry.

When he taunts us, so humourously, in reference to the explosion, by saying, to our discomfiture, that "some grey calicoes spread round the furnace were alone wanting to complete the scene, and put the finishing touch to this exquisite specimen of 'Perkins's Hot Water Apparatus,'" he forgets that this experiment was so amply illustrated in the warehouse of Messrs. Crafts and Stell, that it could not, by possibility, be rendered more striking by repetition. This is a portion of his "Answer," in which he is peculiarly jocular; as if the destruction of "grey calicoes" by fire, and the consequent loss of a great amount of valuable property, were a most amusing exhibition. It can only be compared to the case in which Nero fiddled while Rome was burning. This sort of wit may induce an enemy to smile, but it must, certainly, make a real friend look very serious.

An attempted explanation of an unexpected phenomenon is pronounced to be a "manifest absurdity," because, as Mr. Perkins positively avers, "it is impossible that increase of heat can be produced by the condensation or cooling of steam!!" He must surely have intended this statement as a piece of irony to relieve a dull discussion; for, if he had really any doubts upon the subject, he might have easily and readily proved that the very reverse of his assertion is the fact; and if that failed to satisfy him, he might have demonstrative evidence whenever he may pay his contemplated visit to Manchester.

Mr. Perkins might on this point have consulted authority. An author who treats of his system, and with whose work he may be supposed to be acquainted, says, that "the specific heat of condensed steam, compared with [that of] water, is. for equal weights, as ·847 to 1: but the latent heat of steam being estimated at 1000°, we shall find the relative heat attainable from equal weights of condensed steam, and of water, reducing both from the temperature of 212° to 60°, to be as 7·425 to 1."

Mr. Perkins afterwards says, that "another observation from which erroneous conclusions are drawn," (of course from an error in the premises,) "is that the temperature of the pipes, is influenced by the variation of their internal diameter: this is not the case; the amount of heat conducted off depends on the surface exposed to the atmosphere, and not upon the internal diameter:" from which all that can be inferred is, that Mr. Perkins's pipes must be of a very peculiar kind, when, all other things being the same, the internal diameter affords no indication of their magnitude.

Mr. Perkins tries to evade another explanation by the assurance that "the expansive power of hydrogen gas is far less than that of water." Let us examine this singular statement. Professor Graham, of the London University, says, "Hydrogen gas, steam, and the vapour of sulphuric ether, expand in the same proportion as air."—"The expansion by heat of the different forms of matter is exceedingly various. By being heated from 32° to 212°,

1000	cubic inches of iron become	1004
1000	.... water......	1045
1000	.... air........	1375

Gases are, therefore," he adds, "more expansible by heat than matter in the other two conditions of liquid and solid." Thus Mr. Perkins rests his objection on the assumption that 1000 increased by 375 is "far less" than 1000 increased by 15! The reader can now judge for himself how much, in even this simple case, Mr. P. knows of the properties of the agents which his apparatus requires, and of those which it is liable to bring into action.

Mr. Hood, in treating of the hot water apparatus, says that "a most material difference of temperature occurs in the several parts of the apparatus;" a fact, which we have attempted to explain, but the very existence of which Mr. Perkins denies. It is thus accounted for in the work before us:—"The difference, amounting sometimes to as much as 200° or 300°, arises from the great resistance which the water meets with, in consequence of the extremely small size of the pipes, and also from the great number of bends, or angles, that of necessity occur, in order to accumulate a sufficient quantity of pipe."

"We shall find," says the author, "that a temperature of 450° produces a pressure of 420 lb. per square inch, while a temperature of 530° makes the pressure 900 lb.; and when it reaches 560°, the pressure is then 1150 lb. per square inch. Those who are acquainted with the working of steam engines are aware that a pressure of 45 to 48 lb. per square inch is considered as the maximum for high pressure boilers; but we see that in this apparatus the pressure varies from ten times to twenty-four times that amount. It will also be borne in mind that, in consequence of the extremely small quantity of water used in these pipes, the slightest increase in the heat of the furnace will cause an immediate increase in the pressure on the whole apparatus. For it appears that if the temperature of the pipes be increased 50° above the amount before stated, the pressure will be raised to 1800 lb. per square inch; and by increasing the temperature 40° more, the pressure will be immediately raised to 2500 lb. per square inch; so that *any accidental circumstance which, causes the furnace to burn more briskly than usual, may, at any moment, increase the pressure to an immense amount.*"

Mr. Perkins seems, in some allusions, to insinuate an impression on his part, that we entertain towards him something like a feeling of hostility. Any impression of the kind is, we can assure him, completely unfounded. He is entirely unknown to us, excepting in connexion with his system. We were required to investigate his apparatus *as we found it*; and, without any personal consideration, we conducted that investigation to the best of our knowledge and ability.

In conclusion, we beg to assure Mr. Perkins, that if he can really render his "system" safe, we shall, on being satisfied as to the fact, be quite as ready to recommend it, as we have been to warn the public of the danger which might arise from its use in the state in which it was when we were called upon to examine it.

Report of William Fairbairn, Esq.

Having directed my attention to the experiments recently conducted by Mr. Davies and Mr. Ryder on this apparatus, I have been induced further to extend my inquiries, and to visit several establishments where Mr. Perkins's system of heating has been introduced. Amongst others I may mention those of Messrs. Schunck, Mylius & Co., Messrs. Novelli & Albanelli, as instances where the apparatus has worked satisfactorily for a number of years, and apparently without risk or danger to the buildings. At both places the parties expressed themselves satisfied with the apparatus, and appeared to have no apprehension beyond the alarm and excitement caused by the late accident at Messrs. Crafts and Stell's.

It is true that reflecting persons, and indeed the whole community, have been seriously apprehensive of danger since that accident took place; and Mr. Davies's report, and the opinion of Mr. Ryder, seem conclusive on that point. In fact, it could not be otherwise, as the practical conclusions deducible from the experiments are clear, namely, the singeing of feathers, explosion of gunpowder, charring of wood, &c., are in themselves sufficient evidence of the risk to which the property of individuals is exposed. It is also apparent, that no system of heating is safe where the water, circulating through pipes of small bore, is raised to a high temperature, and subjected to the changes of increased and sometimes suddenly diminished pressure. On this question, therefore, I have no hesitation in giving it as my opinion, that Mr. Perkins's principle of heating is imperfect, and that more particularly from its liability to be overheated, either by improper treatment or a sudden change of temperature, to which the apparatus is at all times exposed.

Mr. Perkins, in describing his apparatus, replies to these objections by stating that, in order to maintain for any length of time an equal temperature, it is only necessary to proportion the furnace to the time the heat is required to be continued, and the damper will regulate the combustion of the fuel, and the heat of the pipes. By this Mr. Perkins means, that the attachment of his heat regulator or governor, as given in his description of the apparatus, will so regulate the admission of air to the furnace, by the expansion and contraction of the flow-pipe acting upon a series of levers, as to open or close the damper according to the temperature or intensity of heat contained in the flow-pipe. Now I have closely examined this part of the apparatus, and although exceedingly ingenious on the part of the projector, it is nevertheless inefficient in its operation upon the furnace, and cannot therefore be depended upon under all the changes to which the whole series is from time to time subjected. Whether this arises from excess of heat in the coils on the one hand, or from a diminution of temperature on the other, is immaterial, as it appears that the apparatus, as now constructed, is liable, either through neglect or otherwise, to almost all the changes of temperature indicated by the experiments of Mr. Davies and Mr. Ryder.

Mr. Perkins, in his description of the apparatus, gives (Mr. Babbage's experiments) the range of temperature in the flow-pipe and chimney as follows:

	Thermometer on Flow-pipe.	Thermometer in Chimney.
	[illegible]	116°
	225	130
	244	132
	249	176
	249	182
	249	178
	249	182
	246	184
	247	146
	235	135
	229	202
Giving a mean temperature during a period of 6 hours of........................	238°	162°

Being an exceedingly low temperature, and such as under the regulations prescribed by Mr. Babbage, would be perfectly safe. But comparing the above with the experiments of Mr. Davies and Mr. Ryder, we have the temperature of the flow-pipe equal to that of melted lead, nearly 400° in excess of that which was considered safe by Mr. Babbage. It is clear that in a series of experiments such as those conducted by Mr. Davies and Mr. Ryder, the temperature of the water in the coils and in the flow-pipe, as it issues from the furnace, might be raised to nearly the melting point of iron; but in justice to Mr. Perkins, I am bound to observe, that it is only an experimental case, no doubt carefully and properly conducted, but certainly not indicative of the general working state of the apparatus.

In Mr. Perkins's system of heating there is, I believe, considerable economy, and convenience in its application; it is not, however, the best, nor yet the most wholesome or safe mode of heating. It appears to me to be liable to the following objections:—

1st. The increase of temperature to which the coils and pipes are exposed, and the consequent danger arising from the ignition of floculent matter, which by accident or neglect might surround the pipes.

2nd. The impurity of the air, caused by its contact with metallic surfaces highly heated.

3rd. Deficient ventilation, where means are not provided for carrying off the impurities, and admitting fresh air at proper intervals.

The above appear to me to be some of the more prominent defects of this system; it is, however, a simple and ingenious apparatus, and provided certain improvements were introduced, I have every reason to believe it be rendered an agreeable, if not a safe and efficacious mode of heating.

In this country it is obvious that large sums of money have been expended on the use and application of this apparatus; and as numerous buildings, shops, houses, &c., are already fitted with all the necessary furnaces, coils, &c., and as it is impossible to change the apparatus for a better all at once, it appears very desirable to adopt such measures as will prevent the possibility of accident, and afford greater security to property. For these objects I would suggest the attachment of a mercurial tube to the flow-pipes issuing from the furnace, with a metallic piston to rise and fall, and by its action on a throttle-valve damper to check the draught in the furnace, and thus reduce the heat whenever the flow-pipe indicates an excess above the maximum temperature.

Again, I would recommend the flow-pipes to be incased in a perforated iron tube, to a distance sufficient to render a reduction of the temperature certain, and to prevent the possibility of ignition, even when in contact with inflammable matter.

These precautions being adopted, and having encircled the furnace by brick work, I should, under such circumstances, consider the apparatus less objectionable, and freed, in a great measure, from the danger which now surrounds it.

Wm. Fairbairn.

Manchester, April 7th, 1841.

ON VENTILATION OF THE COURTS IN THE OLD BAILEY, LONDON.

On the 6th ult. a Court of Aldermen was held for the purpose of receiving a report from the Gaol Committee on the important subject of the ventilation of the courts of the Old Bailey. Dr. Reid was present during the proceedings.

Sir M. Wood brought up the Report of the Committee to whom it had been referred to consider Dr. Reid's plan for improving the ventilations of the courts of the Old Bailey. The committee were of opinion that the plan ought to be adopted. The committee recommended this Court to direct a communication to the Committee for Letting the City Lands, requesting they will present a report to the Court of Common Council, for authority for the work to be proceeded with under their directions accordingly. Sir M. Wood, in conclusion, moved that the Court agree with the Committee in their Report.

The following is the plan, as described officially by Dr. Reid:—

"My Lord and Gentlemen,

"The defective state of the ventilation at the courts in the Old Bailey, which I have examined according to your instructions, arises principally from the following causes;—

"1. The inadequate supply of fresh air.

"2. The imperfect discharge of the vitiated air, a large proportion of which is returned indefinitely upon the person, instead of being removed with certainty and decision.

"The severity of the currents, arising from inadequate diffusion, and the necessary opening of doors and windows from time to time, when complaints are great from the deficiency in the supply of air.

4. The imperfect nature of various parts of the apparatus in use, which presents different causes that render the air less wholesome and agreeable than it otherwise would be.

"5. The contamination of the small proportion of air supplied to a great extent with vitiated air, more particularly from the hall and other passages. In the kitchen there is a cesspool having no connexion with any drain, into which about 30 pails of water are introduced daily during the sitting of the Courts, all of which appears, so far as I have been able to ascertain, to mingle by evaporation with the atmosphere of the kitchen, and to find its way to the sages.

'It will be obvious that defects such as these cannot be effectually remedied without introducing arrangements of proportionate magnitude, as in the original construction of the courts, it could not be expected, from the period at which they were built, that provision would be made for meeting the views now entertained as to the nature and importance of ventilation; while the chambers below and above both courts, excepting on the roofs of the New Court, are so much occupied that few facilities are presented for diffusive ventilation, by which alone any degree of comfort can be given in places so liable to a fluctuating attendance as these courts must be. Under the circumstances, and proceeding upon the assumption that 2000 persons are as many as it would be necessary to provide air for, according to the replies to the various inquiries upon which I entered in reference to this point, I have to propose the following arrangements. It may be proper for me to premise, however, that 2000 persons 12 hours a day in court require air for 28,800,000 respirations during that period, independent of what may be necessary for the surface of the body:—

"1. Let a chamber be provided for the reception of fresh air where it shall escape much of the contamination which it receives at present from eating-houses, chimnies, &c., in the immediate vicinity.

"2. Let the air be filtered from soot as it when necessary with lime-water to remove various impurities, and finally be propelled to the courts by a fanner worked by a steam engine. This ment appears to be the only economical plan that will insure the ve of the courts, considering the peculiarity of their position, and the manner in which they are hemmed in on all sides by different apartments.

"3. Let chambers be provided below each court, that the air may enter diffusively, and as imperceptibly as possible, the diffusion being regulated by perforated zinc or porous cloth at every place represented by the red dotted line in the plan of the courts.

"4. Let a mild hot water apparatus be procured, and let it be arranged in such a manner that by the mere opening or shutting of a valve, it may be made to afford any proportion of warmth, such as the circumstances of the moment may require. I must here remark, that though ventilation may be induced without warming the air before it enters the court, still the two questions are inseparably connected, more especially as in an apartment not ventilated, the vitiated air stagnated around the person produces part of that warmth which ought to be procured from other sources, and which is required to a greater and greater extent, the more freely the air is supplied. To some constitutions the absence of offensive currents, and the supply of air at a proper temperature, are as important as a supply of pure air.

"5. Let the entrance of the air to the court be regulated by a single valve, so that the amount may be proportioned to the state of the external atmosphere and the fluctuating attendance, so that the effect produced upon the person may in all cases be as nearly as possible the same, whatever changes may ensue, either on the attendance at the court or in the external atmosphere.

"6. Let the foul air also be discharged through a single aperture, a valve being provided there also, to be used under particular circumstances.

"7. One external discharge from each court may be provided, but one alone for both would be preferable, but also more costly, from the cuttings required in the roof.

"8. The external discharge should be protected from the action of currents of air by a cowl, or any equivalent modification of the cowl.

"9. The galleries should be supplied with pure air from the fresh air chamber.

"10. A communication should be established between the cesspool in the kitchen and the adjoining drains.

"All the above points are essentially connected with the ventilation of the courts alone, and would cost, as nearly as I can estimate, about 1,925*l.* In stating this sum, it may be proper for me to mention, that a precise estimate cannot be formed, as the precise facilities or difficulties that may be met with in following out the underground cuttings must necessarily modify the result. But I do not consider that there would be a difference of 100*l.*, which might be either less or more than the sum mentioned, according to details that could only be ascertained as the works proceeded. I ought also to observe, that my estimate is founded principally upon the cost of similar works executed in the Queen's Bench and Bail Courts, Westminster, in the Insolvent Debtors' Court, and in various other buildings in London.

"I should not consider the report complete did I not submit for your consideration, that it would be advisable that some minor arrangements should be made for the ventilation of the hall, staircases, and some of the principal apartments in connexion with the courts. In places where the principal room has been ventilated without some attention being paid to lobbies and contiguous apartments, the contrast between the air where ventilation has been introduced and where it has not often leads to complaints that would not otherwise be made, and to the introduction of ventilation in these minor apartments at a future period at a considerable increase of cost. An additional sum of 150*l.* or 200*l.* would enable the ventilation to be greatly improved in all the places now referred to.

"Again, in all buildings constructed in the usual manner there is a defect observed in the movement of air near windows in cold weather, which can be remedied entirely only by double windows; this not being essentially connected with the general arrangements for ventilation, though most important in preventing local discomfort in the seats next the windows, is brought before your notice as a separate question, that can be considered either at present or at a future period.

"Lastly, in making the above report I have to mention, that I have had the advantage of communicating with Mr. Mountague, who has assisted me in obtaining the information required as to the present state of the buildings; and I have the satisfaction to state, that he is of opinion that the several works may be executed without interfering with the character or stability of the building.

"I have the honour to remain, my Lord and Gentlemen,

"Your very obedient servant,

D. B.

Sir P. Laurie seconded the motion. He trusted the Court would be unanimous in recommending the adoption of Dr. Reid's plans. It was universally admitted that he had successfully applied them in the ventilation of both Houses of Parliament, an object of paramount importance, which had often been attempted and as often failed. The best evidence that Dr. Reid had been completely successful in his operation on the Houses of Parliament was to be found in the fact that at the conclusion of his labours they had rewarded his talent and perseverance with a complimentary gratuity of 1,000*l.* over and above the stipulated compe...

The report was confirmed *nem. con.*, so that this complaint will soon be effectually removed.

THE MIASMA OF AFRICA.—NIGER EXPEDITION.

Mr. J. F. Daniell lately read a paper at the Royal Institution, "*On the spontaneous evolution of sulphuretted hydrogen in the waters on the western coast of Africa and elsewhere.*" He commenced by observing, that this subject was now interesting on two accounts—1, because it would recall to the members of that institution the experiments of Sir Humphrey Davy on the subject, and which led him to advise the adoption of ship protectors; and, 2, in consequence of the Niger expedition, fitted out to visit and endeavour to introduce civilization on the western coast of Africa. The effect produced on copper sheathing by the presence of sulphuretted hydrogen in the waters on that coast, was, he premised, well known to every one informed respecting vessels visiting it, and it was a fact that a cruise of nine months on the western coast of Africa injured the copper sheathing of a vessel as much as four years' wear in any other part of the world. The lecturer showed a piece of sheathing taken from the bottom of a Government frigate that had not been many months on the African station, and also a piece from the Royal George, sunk at Spithead, and which had been under water 60 years; the former was eaten through in very many places, and so thin all over that he might push his thumb through it, while the latter was tough and in excellent condition. His attention had been directed to the subject by the Lords of the Admiralty sending him 10 bottles of water, from as many different places on that coast, extending from 8 deg. north of the Equator to 8 deg. south, to analyse, and to report on the component parts thereof, and the accompanying table was the result:—

	Sulphuretted Hydrogen.	Saline Matter.
	Cubic Inches.	Grains.
Sierra Leone, per gallon	6·18	
Volta	6·99	2,480,0
Bonny River	1·21	1,788,0
Mooney	..	2,104,0
Gaboon	..	2,169,0
Lobez-bay	11·69	2,576,0
Congo River (Mouth)	0·67	
Congo River (35 miles inland)		
Bango	4·35	2,736,0
	14·75	1,920,0

All the bottles were hermetically sealed, and he had no doubt the water was in every way as good as when taken from the rivers. On drawing the cork, he was immediately struck with the smell of sulphuretted hydrogen, and adopted the general idea that it arose from animal and vegetable decomposition, but it had since appeared to him that such was not entirely the case. The gas extended a distance of 15 or 16 deg., and in some places as far as 40 miles to sea, covering therefore a space of 40,000 square miles. Now what could the origin be? He thought that it arose from the action and reaction of vegetable and animal matter brought from the interior of the rivers upon the sulphates in the sea water. With this idea he gathered last autumn some leaves from a shrubbery and put them into three jars; into one of which he poured some plain New River water, into the second some of the same water in which three ounces of common salt had been dissolved, and into the third the like water, in which some crystallized sulphate of soda was dissolved. To the covers of the jars he fixed inside some litmus paper, and placed them in a cupboard, the temperature of which varied from 70 to 100 or 110 deg. The effect was, that in the first the litmus paper was perfectly white, and the smell by no means unpleasant; in the second the paper was quite white, and the smell similar to that of a preserve; but in the third jar, in which a sulphate was present, the paper was nearly black, and the stench was horrible and nauseous in the extreme, as every one knew the smell of sulphuretted hydrogen gas to be. Now sea-water contained sufficient sulphates to produce this effect, under peculiar circumstances. But a more interesting part of the subject was the miasma so injurious to life on the marshy shore of Western Africa. Some persons said that if science cannot point out a remedy, it is useless to investigate the causes, but he did not so think; if science could not point out a remedy, still it could point to something as a palliation of the evil. The presence of the injurious gas was easily tested by the roughest hand, so that places in which it abounded could be avoided; and if imperative duty rendered it absolutely necessary to go to those places, then plentiful fumigations of chlorine gas would effectually destroy the sulphuretted hydrogen. The effect of this gas was not only visible on the Western coast of Africa, but in many places elsewhere, although not to so great an extent. Might not the jungle fever of India, the periodical fevers of New York and Charleston in America, and the minor diseases on the coast of Essex, be traced to the effects of this deleterious gas? It was a well known fact that the ships in the mouth of the Medway consumed more copper than other ships. Chlorine gas then destroyed the injurious gas, and it was easily made, and the materials very cheap; the Government had plentifully supplied the African Expedition with the materials necessary for the most perfect chlorine fumigations, and he had the pleasure of believing that his report founded on the analysis of the waters submitted to him, and the precautions taken, had imparted confidence not only to the gallant men who composed that expedition, but also to those who had interested themselves in its welfare.

SEVERN NAVIGATION IMPROVEMENT.

(Concluded from page 247.)

Abstract of the Evidence on behalf of the Worcester and Birmingham Canal Company against the Bill for improving the Severn, given before the Committee of the House of Commons on the Bill, May 17, 18, 21, 24, 25, 27, & 28, 1841.

Mr. F. Giles, engineer, examined by Mr. Austin.—I am a civil engineer, and have surveyed many rivers, harbours, canals, and railways. I am acquainted with the Thames, Mersey, Medway, Ayr, and Calder, and many other rivers; I have also planned the construction of works with reference to the Severn; I have surveyed the Severn with reference to the navigation; I then particularly directed my attention to the drainage and scour of the river, as far as they were compatible with the navigation; I surveyed the river in 1837 with Mr. Rhodes' plans; I have surveyed it partially in the present year. I am acquainted with the plan of Mr. Cubitt. Mr. Rhodes' plan was for a ship canal up to Worcester, and a barge canal up to Stourport. [Witness then described Mr. Rhodes' plan.] That plan was not carried into execution. I have heard the whole of the evidence on the present plans. My objections to it beginning at Stourport are to the proposed solid dams; I object to the principle of damming a river permanently. With reference to this river, it will decidedly obstruct the drainage, and be a great bar to the navigation, when there is sufficient depth of water to pass; and I think a different kind of weir could be constructed that would afford the means of passage in low-water season. In the first place, a solid dam must necessarily raise the summer water level to the height of the dam; when the flood is above the summer water level, supposing it to commence as the summer water is now, not impounded (but you can pound it five, six, or seven feet) supposing the flood to commence rising above the artificial sum, if in the first place the flood rises five feet or more above the original summer water, it must rise it also five feet above the artificial sum of water, and so on every flood it must increase with the rise of the flood in the same degree that the summer water is to the flood.

By Mr. Barneby.—My answer does not refer to the river when bank full, but of course it would fill sooner.

By Mr. Austin.—This plan would affect some of the existing drains, particularly that which is made in the sewer at Worcester, and the drainage up the country from the Salwarp to Ombersley. The drainage is about eighteen inches above the low summer water, and of course the dam at Upton must raise the water permanently in proportion to its height, and thus in flood affect the drainage; and that is not all, for the drainage of the gross matter which comes from the sewers of large towns would be collected in pools, which I think would be a very important matter. The Bevere Island dam in like manner would affect the drainage of the Salwarp; for if the water was penned up below the Salwarp, it would be penned up in the Salwarp too. The Salwarp drains an important district, which would consequently be affected. In my opinion, if oblique weirs would pass more water than straight ones, which I do not think they will, it would not the less affect the drainage of the district. Whether oblique or at right angles the permanent height would be the same, and from that I apprehend the effect to the drainage. The deposit would silt upon the upper side of the weir; and I understand this to be the effect at the weirs on the Ayr and Calder, where they have flood-gates which would assist to remove the deposit. I would have the weirs so constructed as to have two, three, or more flood-gates, sixty feet wide, so as to be open whenever freshes come down; I believe this would have a good effect upon the drainage. With any weir there must be a lateral lock, but when the weir was open there would be no necessity for using the lock. I can form but one opinion of the mode in which it is proposed to construct the weirs—and that is, that they must wash away. I have never built one myself but with solid masonry, and with a puddle bank to back it; I believe a footing is absolutely necessary. I don't hesitate to say that it would be most advisable to dispense with weirs between Gloucester and Worcester; I certainly think the experiment should be tried. I would put a weir above Worcester, at the upper end of the pool, opposite the "Dog and Duck;" I would dredge up to this point, through the bridge at Worcester. I think also the dam at Bevere Island should be at the Salwarp. This would render it necessary to sink the soil at Diglis lock, nothing more. The channel-dredging in the river would necessarily lower the water at the wharfs at Worcester, and it would therefore be necessary to dredge up to the wharfs also; this would improve the drainage at Worcester. It would be necessary to have a dam at Worcester bridge, and to underpin the piers. I think the improvements below Worcester should be executed, according to the exigencies of the case, as they presented themselves during the undertaking. I would first proceed to narrow the river to a certain channel in the soft parts by groins, the points of which would form one grooved channel down the river. I should be able to ascertain the force of the scour as the works proceeded, and thus to regulate the extent to which I would apply the operation of dredging. I should dredge at once in the hard shoals with an inclination of four feet to one; I would propose to dredge six feet for the purpose of obtaining five. I should not let my groins run into the river to the full extent at first, but should add to them, if I found it necessary to do so, to maintain the depth. Deerhurst shoal being wholly composed of sand, it would be an interminable task to attempt dredging alone, but with the assistance of the jetties or groins, I think the scour of the river would maintain the depth required. I think Mr. Provis' mode of throwing in stones for the foundation of his side walls a very bad one. I propose in forming my groins to use stakes of larch, lined in the usual way with faggots. My groins will generally be about 120 yards apart. The quantity to be dredged I estimate at 500,000 cubic yards, which, at 1*s.* per yard, would come to £25,000; the groins I estimate at £28,500; and I have put down £6,000 to be spent upon Worcester Bridge, but I think that is much more than will be required, for I believe £1,000 for each pier will be quite sufficient. Then I have set down £10,000 for contingencies (which is more than 10 per cent.) so we will take the total cost, in round numbers, at £70,000. I was employed by the Worcester and Birmingham Canal Company to form a plan of my own for improving the Severn; this was after Mr. Rhodes' plan had been given up. My plan went before Parliament, but it did not pass.

Cross-examined by Mr. Serjeant Merewether.—I cannot tell you the height of the weir in my plan for improving the Severn, but it was up to high water mark. I have this morning had a model brought here, at the request of an hon. member made to me yesterday, but I should like to speak with Mr. Austin before I produce it. [Here a question arose whether the model should or should not be produced. Previous to the termination of the conversation, it was understood that the Committee would re-examine Mr. Cubitt towards the close of the investigation, to hear his answer to the objections which had been made against his plan.] This plan was suggested by me to the Worcester and Birmingham Canal Company, who paid for the surveys and application to Parliament, and who intended to have carried out the improvement by a commission. The toll was to be 2*d.* per ton from Diglis to Gloucester. I have proposed another plan for the improvement, where the toll to be paid was 1*s.* per ton, but that was for a Company, and not in connexion with the Birmingham Canal Company. It was brought forward in opposition to Mr Rhodes' plan, and when that plan dropped my plan also dropped. I agree with Mr. Walker's regret—as expressed in his report—that so little has been done towards the improvement of the Severn. I do not think that Mr. Cubitt has sufficiently considered the drainage in his plan. I know the situation of Lord Sandys' drain. I went down last Friday night to open it and examine its level, and I knew the drain before. This drain is about 100 yards above Holt Fleet Bridge. The sewer at Worcester, which I mentioned yesterday, has been lately constructed, and I particularly mentioned it because it is the principal one in the city. I was told the fall of that sewer by the person who built it. [illegible] only acquainted with the outfall of that drain. I do not believe the [illegible] is 25 feet. The bottom of the outfall of this drain is 18 in. or 2 ft. above the present low summer level of the Severn, and the sewer is perhaps 5 ft. in height.

Mr. Godson.—The basin in Lowesmoor is at least 20 feet above the low summer level of the Severn.

Cross-examination continued: I have no doubt but that there is a great fall in that drain. I should think the entrance of the drain may be 20 feet above its outfall. I have not heard of any public meeting of the people of Worcester, in alarm at the effect of the improvement on this sewer, but I have seen a gentleman on the subject. It was Mr. Williams, of the Distillery. He resides on the opposite side of the river to where this sewer enters. Where the water, in consequence of these artificial ponds, stops up the mouths of drains, it must impede the drainage. I do not know the particular effect it may have upon this sewer, because I do not know the fall, but the silt will have a tendency to collect at the mouth, and will certainly be deposited at the foot of the weir. The banks are about 16 or 17 feet above the sewer at Worcester. There is not a considerable fall on the Salwarp a short distance from its mouth; there is only a fall of a few inches about a quarter of a mile up the river. The height of the banks of the Severn near the mouth of the Salwarp is about 15 or 16 feet. I do not know the fall a quarter of a mile further up where the mill is situate. I still say that the valley of the Salwarp would be flooded sooner in consequence of the weir at Bevere Island than it otherwise would be. I have never seen weirs constructed as Mr. Cubitt proposes to construct his, but I still think that his weirs would not stand. Though I know Mr. Cubitt well, and know him to be a man of great experience in these matters, I have no hesitation in saying that I believe him to be wrong in the construction of his weirs, both in the mode of forming them and the material to be employed (red sandstone from Holt and its neighbourhood). I never heard of such a weir giving way, because I never heard of such a weir being constructed. I do not believe that Mr. Cubitt's weir will be water-tight, for I do not think the sheet-piling will be water-tight; and I do think that the water leaping over the sheet piling will blow up the stone-work. I think a single row of sheet piles will not be water-tight. I have never seen a weir on the Taff, and I do not know that there is one there constructed by Mr. Cubitt.

By Mr. Hastie.—I have seen the weir at Hampton Court, but it is not applicable to those proposed to be constructed on the Severn, as it is formed of strong piles, having sluice-boards, and I will undertake to say that it has a solid foundation, either of timber or masonry.

Cross-examination continued.—The placing of rubble stone as an apron in front of the sheet-piling will strengthen the weir, if the piling be water-tight. I shall construct my groins with a slight inclination downwards. My groins will be formed of willow stakes wattled; they will be triangular, the base being against the back of the river, and the apex running into the stream. It is a very old mode of forming groins, and groins constructed in this manner were formerly in the Severn at Upton and near the Ketch. They were removed as a nuisance, because they canted the stream to one side. I mean to construct my groins so as to preserve a continuous channel as much as possible. I have certainly no doubt but that longitudinal walls would get a more perfectly continuous channel than the use of groins, if they could be perfectly formed, which I think could not be the case by dropping in the stones, as proposed by Mr. Cubitt. No doubt it would be a great evil for a boat to strike the point of one of my groins. I do not approve of Mr. Cubitt's proposal to take advantage of the deepest parts of the channel, but prefer dredging a straight channel along the centre of the river. There are five arches at Worcester Bridge, and the centre one is 42 feet wide. The total ascent I have by my plan from Gloucester to Worcester race-course is 6 ft. 4 in. The deepest water is under the centre arch and the one to the left. When the water is low, I do not think there is more than 3 feet under the centre arch. I shall first dredge three arches, then a channel 60 feet wide, through the shoal up the race-course, and subsequently dredge up to the wharfs. When I have dredged through the arches and shoal, I should think all the water will be drawn from the wharfs, as it generally is at present. I have been employed for years by the Worcester and Birmingham Canal Company. I do not know that, in consequence of the boats not being able to unload at the Worcester quays, from want of water, they go into the Birmingham canal to unload. I have not calculated the amount nor the cost

Grecian architecture is essentially *wooden* in its construction; it
in wooden buildings, and never did its professors possess either sufficient imagination or skill to conceive any departure from the original type. Vitru-
that their buildings were formerly composed of trunks of
lintels or brestsummers laid across the top, and rafters again resting on them. This is at once the most ancient and barbarous mode of building that can be imagined; it is heavy, and, as I before said, essentially wooden; but is it not extraordinary that when the Greeks commenced building in stone,
of this material did not suggest to them some different and
ed mode of construction? Such, however, was not the case; they set
pillars as they had set up trunks of wood; they laid stone lintels as they had laid wood ones, *flat across;* they even made the construction still more similar to wood, by carving triglyphs, which are merely a
sentation of the beam ends. The finest temple of the Greeks is con
on the *same principle* as a large wooden cabin. As illustrations of history

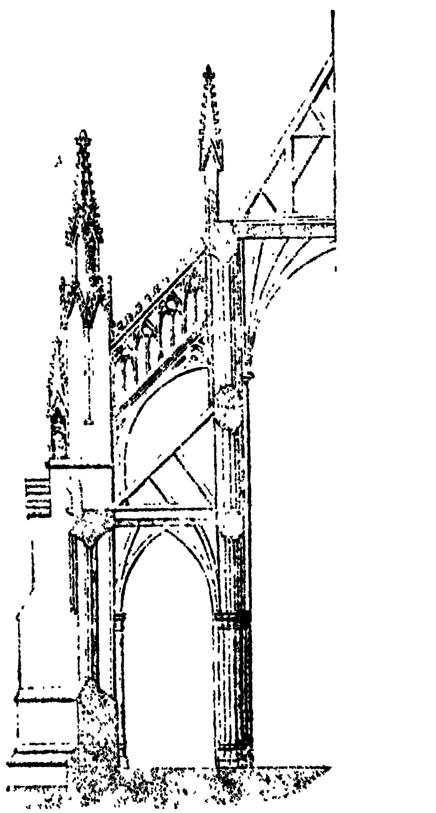
sion d by the weirs, the details of which he expl to they are extremely valuable; but as for their being held up as the standard of architectural excellence, and the types from which our present buildings are to be formed, it is a monstrous absurdity, which has originated in the blind admiration of modern times for every thing Pagan, to the prejudice and overthrow of Christian art and propriety.

The Greeks erected their columns, like the uprights of Stonehenge, just so far apart that the blocks *they laid on them would not break by their own weight.* The Christian architects, on the contrary, during the *dark ages*, with stone scarcely larger than ordinary bricks, threw their lofty vaults from slender pillars across a vast intermediate space, and that at an amazing height, where they had every difficulty of lateral pressure to contend with. This leads me to speak of buttresses, a distinguishing feature of Pointed Architecture, and the first we shall consider in detail.

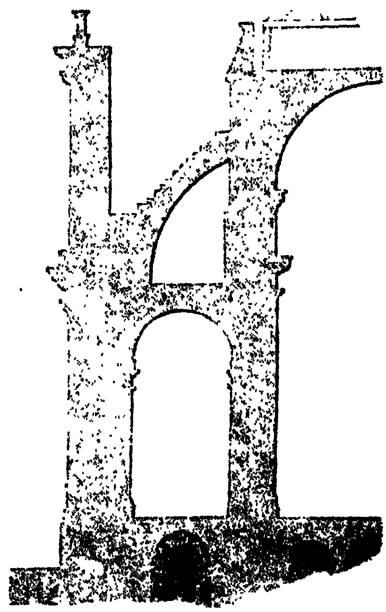
It need hardly be remarked that buttresses are necessary supports to a lofty wall. A wall of three feet in thickness, with buttresses projecting three feet more at intervals, is much stronger than a wall of six feet thick without buttresses. A long unbroken mass of building without light and shade is monotonous and unsightly; it is evident, therefore, that both for strength and beauty, breaks or projections are necessary in architecture. We will now examine in which style, Christian or Pagan, these have been most successfully carried out. Pointed architecture does *not conceal her construction, but beautifies it:* classic architecture seeks to conceal instead of decorating it, and therefore has resorted to the use of engaged columns as breaks for strength and effect;—nothing can be worse. A column is an architectural member which should only be employed when a superincumbent weight is required to be sustained *without the obstruction of a solid wall:* but the moment a wall is built, the *necessity and propriety of columns cease*, and engaged columns always produce the effect of having once been detached, and the intermediate spaces blocked up afterwards.

A buttress in pointed architecture at once shows its purpose, and diminishes naturally as it rises and has less to resist. An engaged column, on the contrary, is overhung by a cornice. A buttress, by means of water tables, can be made to project such a distance as to produce a fine effect of light and shade. An engaged column can never project far on account of the cornice, and all the other members, necessarily according with the diameter of the column, would be increased beyond all proportion. I will now leave you to judge in which style the real intention of a buttress is best carried out.

I have yet to speak of flying buttresses, those bold arches, as their name implies, by which the lateral thrust of the nave groining is thrown over the aisles and transferred to the massive lower buttresses. Here again we see the true principles of Christian architecture, by the conversion of an essential support of the building into a light and elegant decoration. Who can stand among the airy arches of Amiens, Cologne, Chartres, Beauvais, or Westminster, and not be filled with admiration at the mechanical skill and beautiful combination of form which are united in their construction? But, say the modern critics, they are only props, and a bungling contrivance. Let us examine this. Are the revived pagan buildings constructed with such superior skill as to dispense with these supports? By no means; the clumsy vaults of St. Paul's, London, mere coffered semi-arches, without ribs or intersections, *have their flying buttresses; but as this style of architecture does not admit of the great principle of decorating utility*, these buttresses, instead of being made *ornamental, are concealed by an enormous screen*, going entirely round *the building. So that in fact one half of the edifice is built to conceal the other.*



Section of a Pointed Church, with the Flying Buttresses decorated.



Section of St. Paul's, London, a Church built in the revived Pagan style, with the Flying Buttresses concealed by a Screen.

Although we will not go so far as to say it is inconsistent with correct principles of taste to introduce columns merely for the sake of decoration,—a doctrine which if consistently and strictly followed up, would put us out of conceit with the ornamental parts of many Gothic structures also;—we certainly do agree with Mr. Pugin in the main. Beautiful as we consider Grecian architecture to be as regards its mere forms, we have always felt it to be exceedingly *borné* and limited in expression. The whole of it lies in a very narrow compass; it admits of scarcely any combinations; it may, in fact be said to be stereotype. Like a barrel-organ it can play only a single set of tunes, which however agreeable they may be at first, become tiresome by repetition. Antiquarian travellers visit Lycia and other parts of Asia Minor, and merely return with *mare's-nest* discoveries of what we may find just as well, in our own libraries and portfolios; or if they do chance to meet with something like a new idea for a column or capital, scarcely ever is it turned to account, but we go on with our hackneyed Ilissus Ionic, &c., *usque ad nauseam.*—But we are now *improving* upon Mr. Pugin, so let us cut short our own remarks, and return to him and his book.

As it will, doubtless, be ere long in the hands of most of our readers, who will then have the advantage of the numerous illustrations as well as the whole of the text, we shall not attempt to follow its author step by step; therefore, passing over many clever original remarks in regard to 'mouldings,' and the 'use of the splayed form,' &c., we shall notice his free animadversions on the preposterous absurdities passed off by fashionable upholsterers, cabinet-makers, and paper-hangers as

Gothic furniture and Gothic patterns, in the true Brummagem gusto; illustrating some of these mongrel monsters by specimens in his engravings and cuts,—among the rest, of a "New Sheffield pattern for a modern *Castellated Grate!*"

"Modern grates," he observes, "are not unfrequently made to represent diminutive fronts of castellated or ecclesiastical buildings with turrets, loopholes, windows, and doorways, all in a space of forty inches.

"The fender is a sort of embattled parapet, with a lodge-gate at each end; the end of the poker is a sharp pointed finial; and at the summit of the tongs is a saint. It is impossible to enumerate half the absurdities of modern metal-workers; but all these proceed from the false notion of *disguising* instead of *beautifying* articles of utility. How many objects of ordinary use are rendered monstrous and ridiculous simply because the artist, instead of seeking the *most convenient form*, and *then decorating it*, has embodied some extravagance *to conceal the real purpose for which the article has been made!* If a clock is required, it is not unusual to cast a Roman warrior in a flying chariot, round one of the wheels of which, on close inspection, the hours may be descried; or the whole front of a cathedral church reduced to a few inches in height, with the clock-face occupying the position of a magnificent rose window. Surely the inventor of this patent clock-case could never have reflected that according to the scale on which the edifice was reduced, his clock would be about two hundred feet in circumference, and that such a monster of a dial would crush the proportions of almost any building that could be raised. But this is nothing when compared to what we see continually produced from those inexhaustible mines of bad taste, Birmingham and Sheffield: staircase turrets for inkstands, monumental crosses for light-shades, gable ends hung on handles for door-porters,(?) and four doorways and a cluster of pillars to support a French lamp; while a pair of *pinnacles* supporting an arch is called a Gothic-pattern scraper, and a wiry compound of quatrefoils and fan tracery an abbey garden seat. Neither relative scale, form, purpose, nor unity of style, is ever considered by those who design these abominations; if they only introduce a quatrefoil or an acute arch, be the outline and style of the article ever so modern and debased, it is at once denominated and sold as Gothic.

"While I am on this topic it may not be amiss to mention some other absurdities which may not be out of place, although they do not belong to metal-work. I will commence with what are termed Gothic-pattern papers, for hanging walls, where a wretched caricature of a pointed building is repeated from the skirting to the cornice in glorious confusion,—door over pinnacle, and pinnacle over door. This is a great favourite with hotel and tavern keepers. Again, those papers which are shaded are defective in principle; for, as a paper is hung round a room, the ornament must frequently be shadowed on the light side.

"The variety of these miserable patterns is quite surprising; and as the expense of cutting a block for a bad figure is equal if not greater than for a good one, there is not the shadow of an excuse for their continual reproduction. A moment's reflection must show the extreme absurdity of *repeating a perspective* over a large surface with some hundred different points of sight: a panel or wall may be enriched and decorated at pleasure, but it should always be treated in a consistent manner."

These cavalier censures will hardly obtain for Mr. Pugin the good-word of the honourable company of Paper-Stainers and Paper-Daubers. It may reduce the value of their stock on hand, and also of that of the Sheffield and Brummagem artists, at least 75 per cent.; but let them and Messieurs the upholsterers plaister up their pique with the comfortable reflection that, as many people will now be ashamed of their trumpery *Gothicizings*, and proceed to get rid of them as fast as they can, they must have their rooms refurnished,—which will, of course, be all for the benefit of trade.

In his second lecture he again touches upon the subject of furniture, and has another slap at the Upholsterers; who

"Seem to think that nothing can be Gothic unless it is found in some church. Hence your modern man designs a sofa or occasional table from details culled out of Britton's Cathedrals, and all the ordinary articles of furniture, which require to be simple and convenient, are made not only very expensive but very uneasy. We find diminutive flying buttresses about an arm chair: every thing is crocheted with angular projections, innumerable mitres, sharp ornaments, and turreted extremities. A man who remains any length of time in a modern Gothic room, and escapes without being wounded by some of its minutiæ, may consider himself extremely fortunate. There are often as many pinnacles and gablets about a pier-glass frame as are to be found in an ordinary church, and not unfrequently the whole canopy of a tomb has been transferred for the purpose, as at Strawberry Hill. I have perpetrated many of these enormities in the furniture I designed some years ago for Windsor Castle. At that time I had not the least idea of the ... I am now explaining; all my knowledge of Pointed Architecture was confined to a tolerably good notion of details in the abstract; but these I employed with so little judgment or propriety, that, although the parts were correct and exceedingly well executed, collectively they appeared a complete burlesque of pointed design."

This last confession is highly creditable to Mr. Pugin. Such a frank avowal of his own artistical delinquencies, speaks much in his favour, and shows that if he is severe towards others, he cannot be reproached with being over-indulgent towards himself. At the same time we must say that if the censures he levels against architects and their employers be for the most part well merited, they are occasionally too sweeping and overstrained. His objections, for instance, against the application of the Italian style, to domestic architecture in this country, amount to little more than a sophistical tirade. "What," he asks, "does an Italian house do in England?" Which question put forth by him as an unanswerable one, might be turned against the cause he himself advocates; for just as well might it be asked, on the other hand, why should a house erected in the reign of Queen Victoria, be made to resemble one built in the time of Edward IV., or, Henry VII. or VIII? Why should a Protestant church of the 19th century be in any respect modelled like a Roman Catholic one of the 14th or 15th? Is not the Italian style to the full as applicable to our actual wants and purposes in the majority of cases, as any mode *borrowed*—for borrowed after all it must be—from examples to be found, indeed, in our own country, but belonging to periods more dissimilar from, than in aught resembling the present one? Nominally Italian as to design, are not Barry's two Club-houses in Pall Mall, perfectly English in their accommodation? We could easily extend this list of questions; but until they are answered they will answer for the present occasion. Even our ancestors themselves were addicted to change: they endeavoured to make their buildings keep pace with the progress of social improvement and the spirit of the times. Nay, *mutatis mutandis*, what Mr. Pugin himself urges against the castellated style might in some degree be objected to some other styles of much later date.

"What can be more absurd than houses built in what is termed the castellated style? Castellated architecture originated in the wants consequent on a certain state of society: of course the necessity of great strength, and the means of defence suited to the military tactics of the day, dictated to the builders of ancient castles the most appropriate style for their construction. Viewed as historical monuments, they are of surprising interest, but as models for our imitation they are worse than useless. What absurdities, what anomalies, what utter contradictions do not the builders of modern castles perpetrate! How many portcullises which will not lower down, and drawbridges which will not draw up!—how many loop-holes in turrets so small that the most diminutive sweep could not ascend them!—On one side of the house machicolated parapets, embrasures, bastions, and all the show of strong defence, and round the corner of the building a conservatory leading to the principal rooms, through which a whole company of horsemen might penetrate at one smash into the very heart of the mansion!—for who would hammer against nailed portals when he could kick his way through the greenhouse? In buildings of this sort, so far from the turrets being erected for any particular purpose, it is difficult to assign any destination to them after they are erected, and those which are not made into *chimneys* seldom get other occupants than the rooks. But the exterior is not the least inconsistent portion of the edifices, for we find guard-rooms without either weapons or guards; sally-ports, out of which nobody passes but the servants, and where a military man never did go out; donjon keeps, which are nothing but drawing-rooms, boudoirs, and elegant apartments; watch-towers, where the housemaids sleep, and a bastion in which the butler cleans his plate: all is a mere mask, and the whole building an ill-conceived lie."

We would give a trifle to know what is Mr. Pugin's opinion of Windsor Castle;—in fact we should very much like to see a volume of comments from his pen relative to some of the principal modern Gothic structures he has examined in various parts of the country. We do not imagine that he is perfectly satisfied with any one of them ... even with Windsor itself: still, they cannot all be equally bad: some must possess more or less merit in particular parts, or else be conspicuous for egregious sins and defects; and at any rate, we should then obtain something in the shape of specific criticism from Mr. Pugin, instead of those generalized observations to which he has hitherto chiefly confined himself. In the meanwhile, we thank him for the present work, from which much profitable instruction is to be obtained. Considerable praise is also due to the publisher, for the truly elegant manner in which the volume is got up, so as to render it one well fitted not only for the library, but the drawing-room and boudoir; nor is it deficient in the popular recommendation of being unusually cheap.

History of Belvoir Castle, from the Norman Conquest to the ... *Century; with a Description of the Present Castle, and Critical* ... *and the Paintings, &c. &c.* By the REV. IRVIN ELLER, of ... College, Cambridge. 8vo. London, 1841.

We shall confine ourselves to the latter half of this volume, namely, the description of the Castle itself and its apartments, as being that which more properly comes under our cognizance, and which is most to our individual taste. From the first or historical part we content with gathering the following notices in respect to the building. After being wantonly laid in ruins by Lord Hastings, on whom it had been bestowed by Edward IV., the Castle was begun to be rebuilt in the reign of Henry VIII, by Thomas, first Earl of Rutland, and was completed by Henry, the second Earl, about 1555. It was afterwards dismantled by the Parliamentary forces under Cromwell, and again rebuilt in 1638. Excepting some slight alterations, such as the addition of a picture gallery, made by George, the third Duke of Rutland, about 1750, the structure underwent little change until the beginning of the present century, when the new works were commenced in 1801, and carried on under the direction of Wyatt till 1816, at which time the south-west and south-east fronts were completed, and the grand staircase and picture gallery in the north-west one nearly finished. On October 26th of that year a most calamitous fire broke out,* which consumed the whole of the north-west and north-east sides, and would probably have extended its ravages further, had it not been arrested by bricking up the doorway opening from the grand staircase into the Regent's gallery, which, with the chapel, form the south-west front of this extensive pile. Of the pictures destroyed we have here a complete catalogue, with the sums at which each was valued—varying from 5l. to 3000 guineas—and those for which each was insured. Among them were a great many family portraits by Sir Joshua Reynolds, and his large picture of the Nativity, painted for the centre compartment of the stained glass window in New College, Oxford.

After this event the north-east and north-west fronts were rebuilt under the direction of the Rev. Sir John Thoroton,† an amateur architect, who appears to have greatly improved upon the ideas of his professional predecessor, notwithstanding that the latter was no other than the "celebrated" Wyatt. One very material improvement on the original plan, both as regards external appearance, convenience, and internal effect, adopted by Sir John— is the grand entrance in the north-west front, consisting of a spacious advanced carriage porch, connected with the building by a short corridor forming an approach to the vestibule or "guard-room;" whereas, previously to the fire, there was nothing, whatever of the kind—no sheltered intermediate space, but visitors entered immediately from the open air into the vestibule.

"It would be tame language," says Mr. E., "to speak of the present entrance (merely) as an improvement. Nothing can be in better taste than the porch with its lofty doors, its pointed arches, its ogee-shaped canopies with finials, and the cloister-like entrance." "The porch, entrance-passage, guard-room and gallery, were all designed by Sir John Thoroton from portions of Lincoln cathedral. The entrance-passage is lighted by eight windows (four on each side), between which shafts rising from flowered corbels, form the support of moulded ribs on the vaulted roof."

Judging from the plans, we should imagine there must be a striking degree of effect in the view through the arch facing the entrance, into what is called the Guard-room Gallery, formed by a screen of arches on a higher level, it being in fact the first landing, off from which lies the grand staircase. For want, however, of more exact explanation, and of either view or section, it is difficult to comprehend so clearly as we could wish to do, what, owing to the difference of levels, is rather a complex and intricate part of the interior. We may, therefore, express our regret that none of our graphic "Illustrators" and view-makers, should have thought proper to satisfy our curiosity relative to Belvoir. The most that any of them, we believe, have done, is to give us one or two general views of the Castle, but from such points as rather to exhibit its locality, the general character of the structure, and the various masses of building composing it—as seen rising above the lofty trees embosoming it—than to show what its architectural design really is. This is the case with the view (the north-east front), which serves as the frontispiece to the present volume. Greatly do we desiderate a distinct architectural view of the entrance and corridor connecting it with the building; as likewise of another representing that portion of the south-west front which forms the exterior of the chapel, and which is spoken of as being of "purely perpendicular character."

"It has some good features about it," continues the writer, "especially in the parapet above the arcade in the basement story, which formed no part of the original design by Wyatt, but was added by Sir John Thoroton, in imitation of a portion of the parapet in Lincoln Cathedral. The windows are of elegant proportions, and harmonize well with the general character and intention of the building. We might, perhaps, have wished that the embattled parapet of the two towers had been of a rather less gossamer character, and that more had been imparted to the pinnacles. But, upon the whole, the architecture of the chapel forms an exquisite break upon the general plainness of this part of the Castle. It comes view so unexpectedly, and contrasts as effectually with the remainder of this front, as the little cultivated spots which we meet with in the surrounding scenery, when, after passing through the dense foliage of gigantic trees, we suddenly arrive at an open area, where the tasteful skill of the floriculturist has been at work."

We return again to the interior; but, referring to the work itself for descriptions of the several apartments, and of the paintings and other works of art they contain, shall merely enumerate some of the principal rooms, adding their respective dimensions. From the upper landing of the grand staircase, any of the following rooms may be immediately entered. The Picture Gallery (over the Guard-room gallery, and the ascent to it), the Regent's rooms (over the Guard-room or Vestibule), the Regent's gallery, an Ante or Waiting-room, beyond which is the principal library.

Picture Gallery 61.10'×25.8' and 31.5' high, lighted from above by a series of windows fitted with ground glass.
Regent's Rooms.—Sitting-room 24.6'×20.9'.
Bed-room 24.6'×18.
Dressing-room 21×17.9'.
Regent's Gallery, 131×17.8', or, including the semi-circular bay, in diameter, and containing five windows) 35.8'. Height 18.2'. The folding doors at the S. W. end open into the tribune of the chapel.
Ante-room, 30.4'×21.6' with a single window towards the inner court, but lighted principally by a lantern in the ceiling.
Library, 47×23.9' and 18 high; with four windows on the side towards the inner court.
Grand Corridor, extreme length including the staircase on that side of the building, 120×24. Though called a corridor, the proportions and dimensions of this thoroughfare room entitle it just as well to the name of Gallery; and it is in fact occasionally used as a ball-room.
Green or Assembling Room, 27×24, and 17.6' high.
Chinese Rooms: Sitting Room 29×22.
Bed Room 26×17.
Dressing-room 26×17.
Elizabeth Saloon, 55×36, and 20.10' high.
Grand Dining-room, 55×31, and 19 high. Five recesses, viz. one at each end, and three on the side opposite the windows, with two fire-places between them.
Hunters' Dining Room, 21×17.
Family Dining Room, 34×21.

This last is one of the suite of private apartments in the S. E. front; above which is another suite, occupied by the late Duchess; the principal one, a boudoir, 22.1'×19.6', exclusive of the oriel window, which adds 6.3' more to the length of the room, and which commands a most delightful prospect, where "the eye, passing over the foliage on the terraces immediately below the Castle, is refreshed by a beautiful expanse of water, immediately beyond which is rising ground covered with plantations. The village of Woodthorp, in the valley, a little to the left, with the spire of its simple church, is sufficiently distinct to form a sweet feature in this scene of rural repose. At a more remote distance, the magnificent mansion of Mr. Gregory (at Harlaxton), forms a terminal point for the eye to rest upon near the horizon of the landscape."

Here we must take leave of Belvoir—not because little more remains to be spoken of, for we have not even mentioned one principal

* How the fire originated, could, it seems, never be discovered—probably because those who could have cleared up the mystery chose to keep their own counsel. For some piquant remarks on the subject of such "accidents," we may refer our readers to an article in the last No. of the Polytechnic Journal, entitled the British Museum and its Library," where the writer indulges in some pleasantry on the *pyrophobia*—the excessive horror of fires and candles exhibited by the managers of that national institution—which is such that it induces them to close the reading rooms very long before sunset, during several months in the year.

If not as a preventive against fire, at least as a means of checking its progress, we would suggest that in all very extensive residences, particularly where the entire pile consists of distinct masses and parts, there should be exceedingl thick internal party walls between the different ranges of rooms, so that the fire could not spread beyond that portion of the plan where it might happen to break out. Were this done, not only would there be comparatively little danger, but also less alarm and confusion in case of fire, as the inmates would feel themselves in safety in other parts of the building.

† This gentleman, who was rector of Bottesford, adjoining Belvoir, from 1782 to 1820, (in which year he died at Belvoir Castle, Dec. 18th, in his 62nd r.) and who was knighted by George IV. when Regent, deserves to rank have cultivated the study of architecture. "One half of the present Castle," says Mr Eller, "and certainly *the most beautiful* in an architectural point of view, was erected chiefly from his

object of attraction to visitors, namely the Mausoleum, of which, and also of Bottesford Church and its monuments, long descriptions are here given:—but we do so because we have already bestowed as much notice on Mr. Eller's book as our limits will permit. It has afforded us considerable gratification, and we would suggest, for his consideration, whether it would not be desirable to republish the description of the castle, &c., separately in a duodecimo volume, omitting altogether the biographical notices of artists in the account of the pictures; which being done, there would be opportunity for entering into some particulars that are now either passed over or but slightly touched upon. It would be a further improvement were the terraces to be shown in the ground floor plan of the building

---

Graphic Illustrations with Historical and Descriptive Accounts of Toddington, Gloucestershire, the seat of Lord Sudeley. By John Britton, F.S.A. Publisher, the Author, 1840.

By this work, containing twenty-three external and internal views, and nine lithographed plates of details, Mr. Britton has sought to make known to the public one of those modern adaptations of the pointed style to private dwelling houses, the excellence of which he has by his earlier works so mainly assisted to bring about. The energy with which Mr. Britton for more than five and forty years, has continued to superintend the illustration of our ancient buildings, and to direct public attention to their beauties, affords an example well worthy of imitation, and must entitle him to the warm applause of the right minded.

Lord Sudeley, the owner and the designer of the new mansion at Toddington, formed one of the Committee (as Mr. Hanbury Tracy,*) appointed to select from the numerous designs sent in competition for the new Houses of Parliament, and devoted much time and zeal to the investigation. The building under consideration which has occupied his Lordship's attention more than twenty years, proves fully that he was well qualified for the task, having an intimate knowledge of architecture as a fine art. The construction of a modern mansion in the style of buildings of the middle ages is not an undertaking of trifling difficulty. "By a judicious attention to appropriate models," says Mr. Willson in his preface to Pugin's specimens, "a modern residence of whatever size, may be constructed in the Gothic style without departing from sound principles of taste. Some modifications of ancient precedents must be allowed, for an absolute fidelity will frequently prove incompatible with convenience; but as few deviations as possible should be gone into; and above all, nothing should be attempted which is inconsistent with the character and situation of the place, or which cannot be executed on a proper scale of dimensions." This feeling is evident throughout Toddington, and has led to a very successful result, redounding to the credit of its designer the more highly because of the difficulty. Attached to the account of the house is a short essay on the comparative merits and eligibility of the Grecian, Roman, and Monastic or Gothic architecture for the purposes of the modern English mansion, wherein the author traces lightly the progress of architecture in England, and refers to those men who have chiefly aided this progress. In this essay Mr. Britton observes, "of the manner in which architects were employed soon after the Reformation, the household accounts of Henry VIII. furnish some curious but deplorable information. From these it appears that painters, sculptors, carvers, and *architects*, were retained at stipulated periodical wages. Holbein, John of Padua, Lawrence Bradshaw, Richard Lea, and some others were thus engaged; and they designed several of the mansions which were then erected, and which are now more admired in the picturesque drawings and engravings of the artist, than as comfortable residences for the noble or wealthy families of this age. So the châteaux of the old noblesse of France, and the castles of the Edwardian dynasties of England, are picturesque and imposing objects in the landscape, but have few charms or attractions to render them endurable as permanent homes for persons who wish to enjoy domestic quietude and comfort."

For Walpole's advocacy of Gothic architecture, although ill exemplified by him at Strawberry Hill, Mr. Britton gives his tribute of praise, and then describes some few of the better sort of dwellings more recently erected in England in this style.

Want of space however prevents us at this moment saying anything more of the work in question, than that it is a very valuable and acceptable addition to the scanty stock of books which we at present possess on domestic architecture.

* Mr. Tracy was raised to the peerage July 12, 1838.

Illustrations of Windsor Castle. By the late Sir Jeffry Wyatville, R.A. London: Weale, 1841.

This is a folio work in two volumes, on a scale of magnificence but rarely seen, the size of the plates corresponding to the beauty of their execution. These plates are six and twenty in number, besides wood engravings, some of them too containing more than one view, and embracing nearly every part of the external architecture of the Castle and Stables, besides plans of the Castle in its former state. These engravings are executed in a manner so costly that only the devotion of an architect to his favourite subject could authorize, being quite beyond the usual limits of publishing enterprize. The letterpress being printed on paper of the same dimensions, makes the volume rather unwieldly as a readable book, which is to be regretted as the valuable matter contained in its pages is such as to excite great interest. The general superintendence has been confided to Mr. Henry Ashton, and the literary portion by him again transferred to Mr. Poynter, than whom few could be found better qualified. The editors having determined upon excluding a description of the interior of the edifice on account of so much of its decoration being not merely of a passing interest, but adopted against the will of the architect, necessarily restricted themselves to a mere antiquarian description of the Castle. To this task Mr. Poynter has brought a depth of research, which has added much that is new to our previous knowledge of the subject, and given a degree of certainty to many points which before were involved in obscurity. The result of these labours may not be great, but the extent of research required is easily to be appreciated. To transfer to our pages any thing like a complete history of the Castle would be of course impossible, but we cannot allow this volume to pass us without gleaning in some way from its pages.

In the reign of Edward the Third, called the Confessor, we find the earliest authentic notice of Windsor, when it was granted by that last reigning sovereign of the Saxon kingly race to the Abbey of Westminster, under the name of Wyndleshore, a grant which by William the Norman was resumed by an exchange for some lands in Essex. This prince erected a castle at Windsor, which is registered in Domesday Book. At Old Windsor, however, the Saxon kings are believed to have had a palace at an early period. In the reign of Henry III., the castle was rebuilt, and from this period begins to date its historical renown, being in the next reign considered second in importance only to the Tower of London. A few architectural fragments brought to light during the progress of the improvements, are supposed to be the only relics of this edifice. Henry III. made great improvements in the lower ward, and the traces of his work are to be recognized in the present day, during the whole of his reign indeed extensive buildings were in progress. Of the chapel built by this prince, Mr. Poynter is of opinion that a doorway may be recognized behind the altar of St. Georges. In two years the large sum of 873*l*. was allotted to the works. The Belltower the editor attributes to the 25th year of Henry's reign, and to the Garter Tower he is inclined to assign the same date. It is to be observed that during this reign we find frequent provision for chimneys and glass windows; it seems also that the erection of temporary wooden dwellings within the Castle was not uncommon. In searching out the particulars of the works of Henry III., Mr. Poynter has made a very diligent investigation of the Pope and Close Rolls and other records, which have enabled him to employ a minuteness of description equally interesting to the antiquarian and to the architect. Of how much value researches of this nature may become we see when we come to consider how they bear upon any restoration of the western extremity of the Castle.

The next great epoch in the history of the Castle is the reign of Edward III., a period respecting which we have ample information. The foundation of the College and restoration of St. George's Chapel was the first step taken by this monarch, which was succeeded by the inauguration of the Order of the Garter. In 1356, the celebrated William of Wykeham was appointed surveyor, and the works proceeded with great vigour, and in 1359 three hundred and sixty masons were pressed for the service of the castle, and in 1362 on account of a pestilence three hundred and two more. In the first half of 1363 as much as 3802*l*. 17*s*. 8*d*. was paid for the works including 932*l*. for lead, and thirty-six glaziers were impressed, twenty-four to serve in London, and twelve at Windsor. More masons were also impressed. In 1364 the whole expenditure was 3031*l*. 9*s*. 9*d*. In 1365 a payment occurs of 13*l*. 6*s*. 8*d*. to John, a canon of St. Catharine's, the king's picture painter, for a picture with images for the chapel, and another of 50*l*. to John de Lyndesay, for a table with figures also for the chapel. It is to be remarked that then as during the reign of Henry III., the artists appear to have been generally ecclesiastics, dignitaries of the church combining the practice of the arts with their clerical fun[illegible]
In 1365, 600*l*. was paid for lead, and the whole

9s. 9d. To William de Burdon, the king's painter, was paid 13l. 7s. for a great tablet for the altar. In each of the years 1367 and 1368, the expenditure was about 2000l. To William de Burdon was paid 20l. more for his picture for the chapel, 10l. was paid for buying marble, 60l. for German copper for bells, and the very large sum of 200l. for a great alabaster table for the high altar of St. George's. This according to the largest estimate would be 6000l. of the present money. After 1369 no more workmen were impressed, and in a few years the expenditure was gradually diminished; the last payment being in 1374. In this reign from a payment of 50l. for a new bell for it, a clock seems to have been placed in the bell-tower, as has been the practice down to the present day. Of the early works of Edward III. a portion is the Dean's cloister, of other works the outlines are scarcely to be traced, although he added to the castle the upper ward. Here however is yet to be seen the principal gate adjoining the keep. In the interior of the castle the work of Edward III. is still visible in the vaulted basement of the Devil Tower. The arches of this vaulting are four centered, and present an early specimen of the systematic use of that form. By Edward III. most of the buildings of Henry I. were pulled down, and the Keep is supposed to have been rebuilt.

Under Richard II. in 1390, the appointment of Clerk of the Works was for a short time held by Geffrey Chaucer, the Father of Modern English Poetry, his salary being 2s. a day, with the power of appointing a deputy. Under Henry VI. the revenues of Windsor amounted to 207l. 17s. 5½d., a sum far from sufficient to meet the expenses; the manors of Cookham, Bray, Binfield and Sunninghill were farther charged with 100 marks per annum for the repairs.

By Edward IV. the existing Collegiate Chapel of St. George was built, the direction of the works being confided to Richard Beauchamp, Bishop of Salisbury, a most distinguished prelate and architect. In 1480 the expenditure was 1408l. 16s. 9½d. The principal part of the stone came from Tainton in Oxfordshire, where Henry Jennings the master mason purchased 9755 feet at 2d. per foot: the carriage by land through Burford and Culham to Henley cost 151l. 12s., and it was thence conveyed by water to Windsor bridge. Some portion of Caen stone was also used, and Heath stone from Cranbourne Chase. The timber came principally from Upton, Ashridge, Farnham, Wyke and Sunninghill, and the carriage of these materials and of sand and lime amounted to 29l. 10s. 3½d. The cost of scaffolding and other plant, tools, smith's bellows, tiles and tilepins for workmen's sheds, withes to tie scaffolding, straw, candles, seacoal, charcoal, steel, iron for the windows, iron bolts for the carts, sheet iron, tin, tin pans, nails, &c. amounted to 141l. 8s. 1d., and the workmen's wages to 555l. 6s. 1½d. For these works masons were impressed, and the best workmen were so monopolized by the king for St. George's, that other works were sadly impeded, as was the case with the Divinity School at Oxford. Carving seems now to have become a secular employment, and a large sum was appropriated for this class of work, being in this year 75l. 4s. 6d. With the Chapel the Chapter House was also rebuilt. In 1481 stone was obtained from Caen, Tainton, Sherborne, Ryegate, Milton and Little Daryngton, and the expenditure for the year 1249l. 18s. 5d., being for stone 137l. 5s., for carriage 349l. 18s. 0½d., for other materials and stores 141l. 11s. 11½d., and for wages 457l. 10s. 6½d., including 62l. 12s. 6d. for carving. The next year the expenditure was 1115l. 7s. 2¾d., of which for carving 100l. 10s. 4d.; and in 1483 960l. 12s. 10d., of which 186l. 10s. 4d. for carving. Thus in four years out of a total expenditure of 4674l. 15s. 3d., 425l. 7s. 8d. was paid for wood carving. In 1483 Edward IV. was buried here, behind a curious screen of iron work, an elaborate piece of workmanship, generally thought to be of foreign manufacture, but by the editor assigned to John Tresilian, the master smith. Among the benefactions of Bishop Beauchamp to the Chapel, was the following exertion of the influence in its favour. John Shorne or Schorne was a pious rector of Northmarston in Bucks, about the year 1290, and held in great veneration for the virtues which his benediction had imparted to a holy well in his parish, and for his miracles, one of which, the feat of conjuring the devil into a boot, was considered so remarkable, that it was represented in the east window of his church. Bishop Beauchamp obtained a license from the Pope to remove the shrine of John Shorne from Northmarston wherever he pleased, and he accordingly removed it to the Lincoln Chapel at Windsor. At the Reformation, the College of St. George's lost 500l. per annum from the offerings at this shrine. In 1481 Bishop Beauchamp was succeeded by Sir Reginald Bray. Richard III., the last of the Plantagenets, during the first year of his reign appropriated 738l. 10s. 9¾d. for the building of the College and ... In 1484 the body of Henry VI. was removed from Chertsey and buried in the Chapel.

Henry VII. left his personal property and the profits of his lands for the completion of the new works in the body of the Chapel. During his reign the works were directed by Sir Reginald Bray, who built the Bray Chapel, now the South Transept. In 1508 the roof of the Choir was constructed in stone, the expense being supplied by a subscription of the Knights of the Garter. The main vaulting is by the editor cited as without exception the most beautiful specimen of the Gothic stone roof in existence. Henry VII. took down the original chapel of Henry III., for the purpose of building a royal mausoleum in its room, but the work was not completed. The shell of the building is supposed to be of his reign. In 1500 the Deanery was rebuilt by Doctor Christopher Urswick; the houses of the Minor Canons are also attributed to this reign. A lofty oriel in the upper ward and the inclosure of the stairs to the Keep may be assigned to the same date. By a typographical error in the work before us, the death of Henry VII. is assigned to 1503 instead of 1509. The principal work of Henry VIII. was the great gateway of the lower ward of the Castle. In 1528 the ... fan groining of the roof at the interstices of the Cross of the Chapel was executed by subscription of the Order of the Garter. Wolsey began a stately tomb at Windsor in the chapel erected by Henry VII. hence named Wolsey's Tomb House. On this work he employed Benedetto, a Florentine artist, who began it in 1524, and to him were paid 4250 ducats, and 380l. 13s. for gilding. These wo... were destroyed by some of the Parliamentary troops in 1646 for sake of the metal, except a sarcophagus of black marble of Ital... ... sign, which in 1805 was placed over the tomb of Nelson in the crypt of St. Paul's. In 1519 James Denton, one of the canons, founded the building called the New Commons, now incorporated with the Prebendal Houses, but of which a doorway is preserved, richly ornamented. Under Edward VI. in 1537, the fan vaultings of the side aisles to the choir were executed, and works begun for bringing a supply of water to the Castle from Blackmore Park near Winkfield, a distance of five miles. To supply the pipes, Wallingford Castle and other ancient buildings were stripped of their lead, 370 cwt. from Maidstone. Under Queen Mary in 1555 the pipe was brought up into the middle of the Upper Court of the Castle, "and there the water plenteously did rise 13 foot high." In this place was formed a reservoir from which every part of the Castle was supplied. In this reign the houses of the military knights were completed, having been begun in the third year of Philip and Mary, and finished in three years at an expense of 2747l.

... The Square Tower and some portion of the structure to the east were previously standing, and the additions and alterations were made with materials taken from other buildings. The stone ... brought from Reading Abbey, and eighteen fothers of lead, and "twenty old apparails for chimneys," from Suffolk Place in Southwark. To Elizabeth Windsor Castle is indebted for its terrace, although some parts of it appear to have been in existence previously, every ten feet of the terrace wall, twenty feet in height, and six feet at the base gradually sloping to six feet at the top, costing 125l. 16s. 8d. In 1570 1900l. was expended on a thorough repair of the Chapel, supposed to be the private Chapel adjoining St. George's Hall. A general repair of the Castle was made by this Queen, which in the six years ending 1575 had amounted to 6600l. In 1576 Queen Elizabeth's Gallery was built, it now forms a portion of the Library. In the seven years ending 1577 the works had cost 7800l. In the report on the works in 1580, a clause, relating to the apartments of the Maids of Honour, recites that these ladies "desire to have their chamber ceiled, and the partition, that is of boards there, to be made higher, for that the servants look over." In this reign for the first time we have a connected description of the Castle by Paul Hentzner, a German traveller who visited England in 1598. He says that in the Castle ... among other things the horn of a unicorn, eight spans and a half in length, and valued at 10,000l.

Under James I. was executed the survey of the Parks and Forest by John Norden, which contains the first view of the Castle. By an entry in the Issue Roll for 1607, it appears that this survey was presented to the King by its author, who was rewarded with a gift of two hundred pounds. Nothing it is said was done at Windsor under Charles I. until 1635, when several alterations were made. It was the intention of Charles I. to convert the Tomb-house into a place of sepulture for his family, but this plan was not carried out. On the deposition of Charles I., Captain Fogg, an officer of the Parliament, and subsequently, Colonel Venn, under orders from the Commonwealth, carried off the plate decorations of the Chapel and ruined the painted windows. In the reign of Oliver Cromwell many repairs were made, and the revenues of the Castle greatly improved. This prince also attached to the Chapel the foundation of the Military Knights, for whom Sir Francis Crane's building was erected. Under Charles II. a complete alteration of the Castle was made by Sir John Denham and Sir Christopher Wren, and the best artists were employed upon the paintings and carvings of the interior, in which a profusion of the exquisite works of Grinling Gibbon still exist. Charles's principal addition to the Castle was the Star Building, now called the Stuart Building, about one hundred and feet long. Verrio was employed on the allegorical paintings, for which he was to receive a sum of above seven thousand pounds in five years; in 1701, however, 20 years after, 1800*l.* was still due to him. In 1674 St. George's Hall was fitted up as a theatre, and French plays performed in it. In 1676 the North Terrace was enlarged to its present extent. Wren's alterations of the exterior of the Castle were far from improvements, for he left it with a most unpicturesque ap- which it retained for above a century. In 1680 the equestrian statue of Charles II. was erected by Tobias Rustat, Yeoman of the Robes. It is the work of Josias Ibach Strada of Bremen, but the on the pedestal are attributed to Grinling Gibbons. In this reign was commenced the Long Walk. James II. fitted up the Tomb House as a Catholic Chapel, which Verrio was employed in decorating. William III. contemplated great improvements, and employed Wren to draw a plan in the Italian style, which is inserted in the work under our consideration; nothing however was done. Under Queen Anne Sir James Thornhill was employed in painting the Great Staircase, and in the first eight years 40,000*l.* were laid out in repairs. The extraordinary works were principally confined to the Parks.

The two first Hanoverian kings merely kept the Castle in repair, George the 2nd however employed William Kent at an expense ... in restoring some of the paintings. George III. erected the detached edifice opposite the South Terrace, called the Queen's Lodge, which was completed in 1782 at an expense of nearly 44,000*l.*, and is said by the editor to have been executed from the plans of His Majesty, "whose taste for practical architecture is well known." It was removed in 1823 by George IV. In 1787 Mr. Emlyn was employed to restore the interior of St. George's Chapel, at the private expense of George III. In 1796 the painted glass window in the Chapel was completed by Jarvis and Forest, from the designs of West. In 1796 James Wyatt was appointed Surveyor General, who effected many im- 1810 the design of establishing a royal sepulchre was into effect, and a vault constructed under the Tomb House. IV. having decided upon extending the Castle as an imperial ... nt of 300,000*l.* from pa ... the superintendence of the who in 1828 received from the monarch the honour of knighthood, by the title of Sir Jeffry Wyatville. The cost of the whole of Sir Jeffry's works was 771,000*l.*, and they included the following works, new, rebuilt, or thoroughly repaired, New St. George's Gate; New Octagon Turret to Devil Tower; York, Lancaster, Chester, Prince of Wales's, Brunswick, George III., and Round Towers; George IV. Gateway; a great length of walling; a new Turret to the Stuart Buildings; Grand Front of St. George's Hall; Kitchen Gateway; and two octagon Turrets; Gallery from the Devil Tower to St. George's Hall, 5?0 feet long, new terrace 1050 feet long, some part of the ... h, lowering the court-yard from three to

ments with a corridor 500 feet long, kitchen and servants apartments, artments, St. George's Hall; ball-room; Waterloo Gallery; grand ... in the Waterloo Gallery George IV. placed the series of portraits painted by Sir Thomas Lawrence. In the reconstruction of the Keep Sir Jeffry managed with great skill to sustain the increased weight of this enormous pile on an artificial rock of concrete. During the reign of William IV. and Queen Victoria, the works left unfinished by George IV. were successfully prosecuted by Sir Jeffry, until his death in 1840, when the task devolved upon Mr. Henry Ashton, by whom the new stables are being constructed at an expense of 70,000*l.*

As Windsor Castle has employed the talents of some of the most celebrated of our architects and artists, we thought that the following chronological account of officers and persons employed, drawn up by us from Mr. Poynter's materials would prove of interest to our readers.

117?. Master Geoffry, master of the

117?. Master Osbert, ditto

122?. John le Draper and William, the clerk of Windsor, ditto, (Master Thomas, the king's carpenter).

122?. (Master Nicholas, the king's carpenter, allowance for a gown 15*s.*, Master Jordan, ditto).

1228. William de Millars, constable of the castle.

1237. William de Burgh, director of the works.

1240-52. (Friar William of Westminster, a painter, and John Sot his assistant).

1241. (Master Simon, king's carpenter).

1250. (Master John of Gloster, king's mason).

12?1. Richard de Fremantle, Custos of the manor of Cookham and Bray.

13?1. (John de Spalee, master of the stonehewers)

135?. James de Dorchester, deputy constable of the

1356. William de Wykeham, surveyor, (Bishop of ...... salary a shilling a d ... hilling extra while travelling, and three shillings per week for his clerk. He succeeded Robert de and Richard de Rochell who had the same salary. In 1357 Wykeham obtained an increase of a shilling a day.

1358. William de Mulso, canon of Windsor, surveyor.

1366. (John, canon of St. Katharine's, king's painter; John or illiam de Lyndesay, of London, wood carver).

1387. Adam de Hertyngdon, canon of Windsor, surveyor or clerk of the works; (William de Burdon, king's painter).

1390. Geffrey Chaucer, clerk of the works, salary two shillings a day, with privilege of appointing deputy.

1391. Unknown.

1?74. Richard Beauchamp, Bishop of Salisbury, surveyor of the works. (Henry Jennings, master mason; Thomas Canceler, clerk of the works, salary 10*l.*; John Tresilian, master smith, 1*s.* 4*d.* per day. The clerk of the works, master mason and master carpenter had gowns allowed them. Robert Ellis, John Filles, Derrick Van Grove and Van Castel, ca

1481. Sir Reginald Bray, surveyo

1505. (John Hylmer and William Vertue, contractors for the stone the roof of St. Ge

(Benedetto, artist, employed on Wolsey's tomb).

1575. Humphrey Mulhill, clerk of the works; ditto, comptroller, 2*s.* per day; Henry Hawthorne, clerk of the works, 2*s.* per day.

160?. Sir John Norris, comptroller; Sir John Trevor, surveyor of the works.

1637. Sir Robert Bennet, surveyor of the works; (David Ramsay, Esq., king's clockmaker).

1639. (Christopher Van Vianen of Nuremburg, makes the plate for the Chapel).

1660. Sir John Denham, surveyor-general; Sir Christopher Wren, deputy.

16—. Sir Christopher Wren, surveyor-general; Baptist May, clerk of the ......

1676. (Antonio Verrio, painter: Grinling Gibbons, carver).

1679. (Josias Ibach Strada, casts statue of Charles II).

1707. (Henry Wise, landscape gardener).

1710. (Sir James Thornhill, painter).

1746. (William Kent, painter).

1778. George III. builds Queen's Lodge after his own designs.

1787. Mr. Emlyn restores part of St. George's Chapel.

1795. (Benjamin West, painter; Jarvis and Forest, painters on glass).

James Wyatt, surveyor-gener.

1815. (Sir Thomas Lawrence, painter).

1824. Sir Jeffry Wyatville, surveyor-general; (Sir Richard Westmacott, sculptor).

1840. Henry Ashton, architect.

The description of the plates is far from being so copious as we could wish, being confined principally to an account of the alterations made by Sir Jeffry Wyatville; but it is but fair that we should mention that Mr. Poynter is not responsible for this portion of the work. It is mentioned in describing the Round Tower, that Sir Jeffry being unwilling to disturb the associations of the spot, has provided holes in the stonework of the Castle for the jackdaws and starlings who build here in numbers, to form their nests in. They are for the most part invisible from below, except between the corbels of the battlements of the Keep. From the level of the road on the west side, to the top of the flags left of the Keep, is a total height of 203 feet, of which the Flag Tower is 25 feet, and the flag staff 30 feet; the diameter of the Keep is 102 feet.

On the Nature, Properties, and Applications of Steam, and on Navigation. From the seventh edition of the Encyclopædia ... nica. By John Scott Russell, M.A., F.R.S.E. Edinburgh: Adam

The volume before us comprises, in addition to the articles on the above subjects which are printed in the Encyclopædia, an historical account of the origin and progress of the art of steam navigation down to the year 1839, by the same author; besides the account of the locomotive steam-engine, from the Treatise on Railways by ...

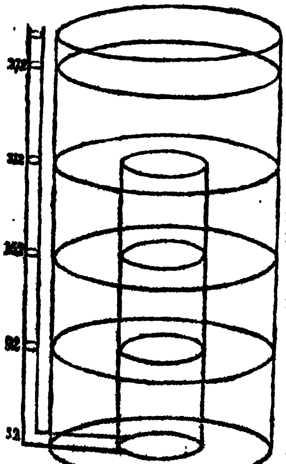
The present articles, STEAM and STEAM-ENGINE, in the Britannica, are intended to contain all that was interesting ... in the original articles (written by Dr. Robison,) with Mr. Watt's notes, enriched by the results of subsequent labour and research; been the author's aim, as he states in the preface to the ..., "to add to all that Robison had originally said of

Watt's invention, what he would have required to add if he had lived to witness its present extended use, its multifarious applications, its varied forms, its modifications in material and construction* He has endeavoured to place before the reader, in a simple form, all the most important information which many years of research and of practical experience in a favourite subject have placed in his possession; and "the reader who is familiar with the subject will," he says, "readily discover that he has read and thought for himself, and that his errors, if many, are at least his own. In one point he trusts he has facilitated the progress of the student. While giving the general reasoning of complex calculations, he has endeavoured to disembarrass them as much as possible of that parade of calculus which exhibits the author at the expense of the reader; and rather to present their results in that simple form in which alone great truths present themselves to those who thoroughly understand them."

The plan of the work here laid down is in accordance with the nature of an Encyclopædia, which, being a work of a popular character, and a book of reference rather than instruction, many, if not the majority of its readers, moreover, being uninitiated in the arcana of abstruse mathematical science, and therefore willing to take for granted the truth of propositions, the demonstration of which they are unable to comprehend, should not be unnecessarily encumbered with complex and difficult calculations. It should, however, at the same time be borne in mind that some, and we trust we may say many, of the readers of the Encyclopædia are possessed of sufficient scientific knowledge to enable them to think and judge for themselves. Therefore, although the facts advanced should in general be such as are recognized by the best acknowledged authorities, and in support of which it suffices in most cases to cite the authority, yet, when any *new* proposition is enunciated, or any new doctrine propounded, it should be accompanied by a rigorous demonstration, or it must incur the risk of being rejected as unfounded. There are two instances in the work under review, in which we do not find the reasoning adequate to justify the conclusion; we allude to the determination of the *best vacuum* in the condenser of a steam engine, page 276, and of the best proportion of power to tonnage in sea-going vessels, page 288. We must, however, remark, in justice to the author, that we have seldom, if ever, met with a work so full of typographical errors, by which so much unnecessary labour is imposed on the reader, that many are deterred from attempting to make themselves masters of the author's meaning, and which are in some cases so serious as perhaps even to render the accomplishment of the task impossible. Some of the errors are of such a nature that it is difficult to decide whether they are to be ascribed to the author or to the printer.

The article STEAM, which occupies nearly the first half of the volume is on the whole a valuable contribution, particularly the second section, in which are collected together all the most recent experimental researches concerning the elastic force of steam at different temperatures, as well as the most esteemed of the earlier experiments, accompanied by figures of the apparatus employed.

In the first section, where the properties, phenomena, and application of steam are considered in a general manner, there is the following simple illustration of the doctrine of latent heat by Dr. Dalton, from which those who are not familiar with the operations of heat may form a tolerably correct notion of the phenomenon in question:



The liquid and its vapour may be considered as two reservoirs of caloric, capable of holding different quantities of that fluid. Let figure 1 represent to us such an arrangement; the internal cylinder of smaller capacity, the external one of enlarged capacity surrounding and extending far above it, and a small open tube of glass, communicating freely at the bottom with the internal cylinder. Let us now conceive water to be poured into the internal cylinder, the water will manifestly flow into the slender tube till it stand on the same level in the tube as in the cylinder. If any additional quantity be now poured into the internal cylinder, the rise of water in the slender glass tube will serve as an index of the quantity of added fluid; and when it is filled to the top, the fluid will stand at the height marked 212°, and will still be a correct index of the addition of fluid. But if more water be now added to it, it will not make its appearance in the slender tube, but will simply overflow from the internal cylinder over into that of enlarged capacity, so that, while a large quantity is passing into the vessel and gradually filling it up to 212°, no additional rise takes place until the whole of the outer cylinder becomes filled to that point, after which any further addition will again become sensible, by a corresponding rise in the tube. This process is in precise analogy to the succession of circumstances in heating a liquid, and converting it into steam. The internal cylinder represents the liquid, the external one the vapour of greater capacity, and the slender glass tube at the side the thermometer placed in communication with them. When heat flows into the liquid, it passes equally into the thermometer; and each increment of the one produces an equal increment in the other, until the liquid reaches the limit of its capacity, when it suddenly begins to enlarge its bulk and take the form of steam; but the quantity of heat required to fill up this enlarged capacity is so great, as to require about 5½ times as much to fill it as was contained in the whole liquid before, so that all this time the thermometer is standing still, and it is not until the whole of the steam is thus supplied with 212° of caloric, that the thermometer will begin to show any further elevation; after which, any increment of heat thrown into the steam will make its appearance on the thermometer, and proceed as formerly, by simultaneous increments.

As a practical application of the influence of pressure on the boiling point of water, the following rule is given for finding the heights of mountains by boiling water:

Boil pure water in an open vessel at the bottom of the elevation, and observe on the thermometer the point at which it boils. Boil it again at the top of the mountain, and observe with the thermometer the point at which it now boils: the difference of temperature, multiplied by 530 feet, will give a close approximation to the height of the upper above the lower station.

This will give an approximation; but, if greater accuracy be required, it will further be necessary to correct for the difference of the temperature of the air at the two stations, in the following manner. Add the temperatures of the air at the stations, and subtract 64 from their sum, multiply the remainder by one thousandth part of the height found; and this will be the correction to be added to the height formerly found. The result thus found will still require a slight correction for the figure of the earth and latitude of the place; but this does not amount to more in our latitude than an addition of about two feet in a thousand, which forms a second correction.

To illustrate the mode of deducing heights from the boiling point, as we have given it, we take the following example.

Water boils on the top of Ben Nevis at 203·8°, while at the side of the Caledonian Canal it boils at 212°, the temperature being 30° on the summit of the mountain, and 35° below. In order to determine the height,

From 212°	
Take 203·8°	To 30°
	Add 35°
There remains 8·2°	
Multiply by 530	Sum 65°
	Subt. 64°
246·0	
410	Remain 1° mult. by 4·346
4346 first approx.	Latitude 56° nearly
4 first correct.	Mult. 4·350
	by 2·
4350 second approx.	
8·7 second correct.	8·700

Calc. height, 4358·7 third approximation.

4358· true measured height—the difference being less than 1 foot.

This method, however, is seldom susceptible of so high a degree of accuracy, even with the most carefully conducted experiments.

There is also a description with explanatory figures, of the elegant and compact apparatus contrived by the Rev. F. J. H. Wollaston for facilitating the procedure of taking the observations with the requisite precision.

Among the contents of the second section we may mention, as particularly worthy of notice, the abridged account of the experiments undertaken by the French Academy of Sciences, and conducted principally by the M. M. Arago and Dulong, having for its object the discovery of the relation existing between the temperature and elastic force of steam; and those conducted, with the same object, by the committee of the Franklin Institute of Pennsylvania, appointed to examine into the causes of the explosions of the boilers used on board of steam-boats, and to devise the most effectual means of preventing the accidents, or of diminishing the extent of their injurious effects. The former were completed in 1829, and are in every respect entitled to a larger share of confidence than the latter, as well on account of the greater perfection of the apparatus employed and the extraordinary care bestowed upon the manipulations, as the names of two philosophers so well versed in experiments of a similar nature.

In the 3rd section, *on the mathematical law which connects the elastic force of vapour with its temperature*, Mr. Russel has certainly laid before his readers a considerable collection of formulæ (15 in number)

* The article on the Steam-engine is, we believe, published in a separate volume; but, as we have not yet seen it, we are unable to notice it in this month's Journal.—ED. C. E. & A. JOURNAL.

previously proposed by divers authors to represent that law, none of which are applicable but in a limited extent of the scale; but we are surprised to find that he has made no mention of that proposed by Mr. A. A. Mornay in the second volume of our Journal, page 200, which represents Dalton's experiments below 212°, and those of the French Academy up to 24 atmospheres, (beyond which they did not extend) within 2·45 degrees Fahr. at the latter limit, where a new formula, proposed by the author of the present work, gives a difference of 10·26 degrees.

In the reasoning through which he arrives at this formula, we rather suspect that Mr. Russell has fallen into the error he deprecates so much in his preface—that of *exhibiting the author at the expense of the reader*, though we think his *parade of calculus* only calculated to dazzle the very ignorant, without being intelligible to the mathematician. What, for instance, do the series α, β, γ, and the equations δ, ϵ, (page 113) signify? We confess they are above our comprehension, but perhaps some more profound mathematician might be able to explain their meaning, and to point out their connexion with the laws of temperature and pressure, mentioned in the previous part of the paragraph, and with each other. By some means, however, we are led to the equation, (page 116)

$$\frac{t+121^\circ}{333^\circ} = (1\cdot11401)^{\frac{\log F}{\log 2}} \quad . \quad . \quad . \quad T$$

which appears in an entirely different form from any other that has been published, but which differs in fact from Tredgold's only in the values of the constants; it is, indeed, when freed from logarithms, nothing more or less than the following:

$$F = \left(\frac{t+121}{333}\right)^{6\cdot42}.$$

Mr. Mornay's formula alluded to above, possesses this great advantage over the others, that it furnishes a very simple equation for finding the elastic force of steam in terms of its density alone, which is necessary in calculating the effect of steam used expansively in steam engines. Regarding the density of steam Mr. Russell has given no calculations at all, although, besides the formula just alluded to, one has been proposed by Mr. Navier, and a modification of it employed by the Count de Pambour in his *Theory of the Steam Engine*, published in 1839; but there is in the 4th section a very comprehensive table of the density of steam at different temperatures, by Gay-Lussac, as well as an engraving and description of the simple and elegant apparatus used by that philosopher, with his method of operating.

The 5th section, *on the application of our knowledge of the properties, phenomena, and laws of steam to practical and economical purposes*, is interesting as far as it goes; but, as we stated at the beginning of this notice, the most important application, the Steam Engine, is published in a separate volume.

The article Steam Navigation might, with greater propriety, be entitled "the Steam Navigation of Scotland and the United States," the share of that part of Great Britain called England being represented by the following paragraph:

"To the talent of Mr. Maudslay of London, the present marine engine owes the introduction of that high degree of precision in its construction and details, which gives it so much durability and efficacy as a machine."

From the tenor of this article it would appear that the author was utterly ignorant of the numerous steam boats with which the river Thames is studded at all hours of the day, and some of which vie in speed with the vaunted American steam boats, and that he knew of no steam vessels which navigate the ocean with other than Scotch engines. He does not say (is he ignorant of the fact?) that the Great Western, with Maudslay's engines, makes better passages to New York than the British Queen, with Napier's. The history of the progress and present condition of the art, as here traced, thus bears reference only to the two countries named above—Scotland and the United States; it is, however, as such, interesting enough, but would be rendered much more so, if combined with the history of the art in England.

The following paragraph in page 268, taken in conjunction with the omission of all mention of Maudslay's four cylinder engine, and with the description of Humphreys' trunk-engine, accompanied by a wood cut, in the preceding page, would corroborate the opinion that the author had but a very limited knowledge of the state of Steam Navigation in England.

For a like purpose, oscillating cylinders have been used with some measure of success. Rotatory engines have been unsuccessfully tried. The reader may now examine the vertical engines in the plates.

We believe the only trunk-engine yet made is that of the Dartford, which turned out a failure, while many steam boats now running on the Thames are fitted with oscillating engines, among which are some of the swiftest boats on the river.

We copy the following proof of the doctrine that *the vacuum in a condenser may be too good*, or rather that any improvement in the vacuum beyond a certain limit must be obtained at the expense of more fuel than it is worth; because it is not altogether without foundation, but, by reason of false notation, seems a tissue of absurdity and contradiction.

Let t = the caloric of water of 1°.
c = the constituent caloric of water in the state of steam.
e = the total force of steam in the boiler in inches of mercury;
and x = the elastic force of steam at the temperature of best condensation which we seek to discover.

Then from the law which connects the elastic force of steam with temperature, as already determined in our treatise on Steam, it follows, that in the case of maximum effect, or the temperature of best condensation,

$$\frac{t}{c} = \frac{x}{e} \text{ that is } x = \frac{e\,t}{c}$$

now $c = 1000$, and if the steam in the boiler be at 5 lb. above the atmosphere, or if $e = 40$ inches of mercury, and $t = 1$.

$$x = \frac{40}{1000} = 0\cdot04$$

Again, if the steam be at 7½ lb. = 45 inches,

$$x = \frac{45}{1000} = 0\cdot045$$

Again, if the steam be at 10 lb. = 50 inches,

$$x = \frac{50}{1000} = 0\cdot05$$

Hence, we find that the best elasticity or temperature in the condenser depends on the elastic force of the steam in the boiler.

With steam of 5 lb. in the boiler, the elasticity of maximum effect in the condenser is at 93° of Fahrenheit, and the best vacuum in the barometer is 28. With steam of 7½ lb. in the boiler, the elasticity of maximum effect in the condenser is 95° of Fahrenheit, and the best vacuum in the barometer is 27·8. With steam of 10 lb. in the boiler, the elasticity of maximum effect in the condenser is 97°, and the best vacuum in the barometer is 27·5. In like manner it would be found that with steam of 50 lb. in the boiler, worked expansively, as in Cornwall, the best vacuum in the condenser would be about 26° on the barometer.

Our first impression on reading this proof was that it was altogether fallacious, and, as the calculation was not supported by reasoning, it was not likely to convince us of the contrary; but, on consideration, it seeming probable that the general proposition was true, although Mr. Russell's equation was not the interpretation of a truth, we investigated the subject more closely, and found that this equation did not represent the author's own opinion, but that x ought to stand for the increment of elastic force due to the increment t of heat at the temperature of most advantageous condensation, that c ought to represent the total quantity of caloric required to evaporate water from that temperature, and not merely the amount of latent heat at 212°, and that e should express, not the total pressure in the boiler, but the mean effective pressure on the piston before the allowance for friction has been deducted. The equation should therefore stand thus, retaining x with the signification first assigned to it by Mr. Russell, and expressing by *dif.* x a very small difference of elastic force, and by *dif.* t the corresponding very small difference of temperature,

$$\frac{dif.\,x}{e} = \frac{dif.\,t}{c};$$

the explanation of which is as follows:

The first member expresses the ratio of an assumed small gain of power to the total power exerted by the steam, and the second member the ratio of the quantity of heat thereby abstracted from the feed water (which must be restored in the boiler at the expense of a proportionate quantity of fuel) to the total amount of heat requisite to convert it into steam, or, which is the same thing, the ratio of the extra fuel to the total quantity used. Now it is obvious that, if these two ratios are equal, that is, if the increase of power is in proportion to the increase in the consumption of fuel, there is no gain of duty, and, of course, if the second member were greater than the first, the result would be a diminution of duty.

If we make the small difference of temperature = 1°, as Mr. Russell has done, *dif.* x will express the increment of force due to an increment of 1° of temperature; and, if we suppose the best temperature of condensation to be 100°, we shall have $c = 112 + 1000 = 1112$, and the above equation may be put in the form,

$$dif. x = \frac{e}{1112}.$$

If the pressure in the boiler be about 5 lb. above the atmosphere, we shall not have a greater mean pressure than about 30 inches in the cylinder, in which case

$$dif. x = \frac{30}{1112} = 0{\cdot}027.$$

This is about the difference between the elastic force of steam at 72 and 73 degrees, according to Dr. Dalton's latest experiments, and the force at 73° is 0·95 inch; so that, when the mean pressure in the cylinder is 30 inches, and the barometer without stands at 29½ inches, the condenser barometer should mark 28·55 inches.

The calculation of the best proportion of power to tonnage (page 288) is so confused by errors (of the press?), that we have no leisure at present to wade through it.

The article on *the immediate Mechanism of Propulsion* is defective in as much as the Archimedean Screw Propeller is not so much as mentioned, and the author seems to have formed an erroneous idea of the principle of Morgan's Paddle Wheel, in consequence of a trifling resemblance which it bears to Oldham's Wheel. See the article *On Paddle Wheels* in the Appendix to the new edition of "Tredgold on the Steam Engine."

The Historical Sketch of Steam Locomotion, by Lieut. Lecount, forms an interesting appendix to the work, which on the whole contains much useful information on the subject of steam, perhaps more than is to be found combined in any other volume of its size, although we do not think it does full justice to its title, particularly in what regards Steam Navigation, as we have already observed.

ON WIERS OR DAMS ON RIVERS.

Observations on the Effect produced by erecting Weirs or Dams on Rivers, and on their efficacy for Navigation Purposes.

By William Bull, Civil Engineer.

Weirs are generally erected either for the purpose of raising a head of water for the use of mills, or for the purpose of navigating the channel of a river, and they cause in the first instance a permanent elevation of the ordinary surface of the water.

If a weir has the same length of top surface as the section of the river at the place where it is erected, it will cause such flood waters as would have been retained within the natural banks of the river, before it was erected, to rise above them in proportion to its height, and overflow the adjoining lands if artificial embankments of proportional height are not erected to prevent it.

When more water comes down the river than its banks could have previously held, then, although the weir causes an increase of height, the evil is less in proportion than in the former case.

In extreme floods, when the water would rise far above the surface of the valley, the small increase of height caused by the weir is of little or no consequence, as other causes generally exist, such as embanked roads leading to bridges, and the contraction of the stream by the bridges which obviates the effect of the weirs; unless the latter be situate at or close to the bridge.

Weirs cause the beds of rivers to rise by retaining the sand and gravel brought down by the stream, with much more rapidity than the adjoining lands rise from the deposit of lighter silt first in the upper portions of the rivers where they are erected, and ultimately throughout their course as far as the weirs extend, by which the sectional area of the rivers is diminished and of course the land adjoining rendered more subject to floods.

This is an evil that may be partially remedied by dredging and embanking. I say partially, because, from the manner in which the former is usually done, (*i. e.* only with a view to keep open a narrow channel in the river for the use of boats,) it has very little tendency to produce it, and if done to the whole extent of the river, would become a very expensive operation, and the latter, even when well executed at first, being constantly liable to delapidation, is for ever subjecting the lands to inundation. This is particularly illustrated in Holland, where the rivers, having been dammed up and embanked, have been permanently elevated above the adjoining lands, and where destructive inundations are by no means of rare occurrence.

Where no weirs exist, rivers have generally a tendency to deepen their beds (particularly if the water is confined to a channel of moderate width) from their source to their confluence with the sea, or until they arrive at an estuary or low flat track of land, when the sand and gravel or other material driven or borne down by the water, is either deposited in such estuaries or on bars at the river mouths, or is dispersed along the shores of the sea by the tidal wave.

I have observed many instances of the gradual lowering of the beds of rivers, but more particularly one which has recently come under my observation, where the out-fall of a mill-goit has been lowered two feet in about four years. This phenomenon is, of course, most obvious where the fall in the river is greatest, all other circumstances being equal.

By making a weir of greater length than the general section of the river, and by widening the river above and below the same, a part of the injury to adjoining lands by raising the surface of the water may certainly be avoided, so long as the river is continued of the increased width, and by extending the length of the weir and the widening of the river to a great or almost indefinite extent, both in line of the current as well as in width, the injury to adjoining lands may be nearly if not entirely obviated for a limited time, but it can only be for a limited time without constant care and attention, and a considerable periodical outlay, (much more of each than is usual or likely to be devoted to such purpose,) because, from the surface of the water being extended, the stream will become proportionally sluggish, particularly towards one or both sides, where, as well as in the natural bed of the river, the matter brought down by the stream will be deposited, and the river will again assume its original width or nearly so, and render the increased length of the weir of little or no avail. The time which will expire before the river assumes its original width will depend materially on the quantity of matter held in suspension by the water, or driven forward by the impetus of the stream, and on the velocity of the stream above and at the point where the weir is erected.

In such instances as where, for some distance before arriving at the weir, the fall and consequent velocity of the stream is of a moderate degree, and where the upper surface of the river has been enlarged, and thereby the velocity of the current diminished, there being only a light alluvial matter and sand held in suspension, or driven forward by the stream, such matter will be rapidly deposited on the sides of the river, until the sectional area is again so contracted as to increase the rapidity of the current to its original rate.

If, instead of the fall and velocity being of that moderate degree which will only carry forward the lighter matter, it is of such a degree as to force down gravel and other heavy matter, the length of the pond first caused by the erection of the weir will be gradually diminished, until the whole of the original bed of the river is filled up to the weir, so as to form the inclination of the new bed at nearly the same angle as it was before the weir was erected; but in this case the contraction of the stream to its original width will go on much more slowly than in the former case, arising from the filling up of the bed, causing the velocity of the stream to be reduced in a less ratio than it would have been if the heavier matter had not been brought down into the original bed of the river.

If the bed of the river is constantly dredged, so as to keep it of its original depth to the upper end of the pond formed by the weir, then the top surface will contract much more rapidly than in the last case, until it arrives at or approximates to its former width, as in the first case by reason of the heavy material being prevented by the dredging from raising the body of the stream so much as it would have done had no dredging been used, and the consequent less velocity of the stream allowing the lighter matter to be deposited at the sides.

From the foregoing observations it will follow that the increased length of the weir, and accompanying width of the river beyond its former dimensions, renders but a partial and temporary advantage, in diminishing the damage to adjoining lands arising from the erection of such weir, and that such erection, whether of greater length than the section of the river or not, does not in itself provide a permanent means of navigation.

Many instances of the inadequacy of weirs for supplying a permanent means of navigating natural rivers may, I have no doubt, be adduced. In the instance of the Calder and Hebble navigation, where I have been practically acquainted with the subject for the last eight years, they are abundantly manifest, as well as in the adjoining navigation of the Aire and Calder, with which I am well acquainted, the proprietors of both of which have been for many years adopting means to avoid the natural stream by substituting cuts or canals.

When first the River Calder was made navigable, it was divided into pools by weirs of sufficient height to give the required depth of water and these weirs were passed by means of locks; but it was soon found that the matter brought down by the stream was rapidly filling up the pools, and consequently diminishing the depth of water, whereby the navigation was much impeded; this was first most apparent at the upper ends of the pools, where the heavy materials, such as gravel and boulders, were first deposited on coming in contact with the comparatively still water produced by the weirs, and as the stream advanced, by deposit of the sand and lighter materials further down. At first recourse was had to remedy the evil by raising the weirs by means of boards, which were frequently washed away by the floods, and had to be renewed as the water subsided, and partly by raking the gravel and sand to the sides of the river. But as soon as the power of the dredging engine became known, recourse was had to it; it was, however, still found that although they had procured and kept in constant work two of these engines, the deposit was gaining on them; they therefore had recourse to the adoption of canals, as before stated, commencing with those parts which were the most affected by the deposit, until they now use only a little more than four miles out of a distance of twenty-two miles of the river. The Aire and Calder Company now use about nineteen miles out of forty-three, by having recourse to dredging, and raising their weirs by means of boards, as before described. That they are enabled at present to navigate a greater proportion of the rivers than their neighbours, no doubt arises principally from the circumstance of their being situated further down the stream, and their being numerous weirs above, which retain the sand and gravel from coming down to them.

I cannot conclude these remarks better than by giving the result of my observation and experience, which is that converting natural rivers into artificial navigations by erecting dams across them, is much to be deprecated. First, because the dams cause the adjoining lands to be more frequently overflowed than they otherwise would be. Secondly, because dams obstruct the ordinary drainage of the country. Thirdly, because the object sought is but imperfectly obtained, and lastly, because it is the means of materially retarding, if not of entirely preventing, the adoption of the more efficient means of providing for inland navigation by artificial canals, which, if made at all, are rarely or never made so complete as they would have been had no attempt been made to adapt the natural rivers.

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

INSTITUTION OF CIVIL ENGINEERS.

March 9.—The PRESIDENT in the Chair.

"*Description of the Arched Timber Viaducts on the Newcastle and North Shields Railway, erected from the designs of Messrs. John and Benjamin Green; and on the application of the same system of construction to oblique and other Bridges, to the Roofs of Railway Stations, and to other large Buildings.*" By Benjamin Green.

The construction of viaducts and bridges forms so important an item in the cost of a railway, that the engineer is induced to devise new methods of completing his works with due regard to stability and durability, and at the same time with the least possible expense. Stone and brick have been the materials most generally used for bridges; cast iron has been introduced where the heights were too low for the spans, in large arches, or in trussed beams where a certain clear space beneath was required, with only a limited height to the level of the rail. Timber, from its lightness, strength, and cheapness, has been extensively used, but only in spans of limited extent, owing to the sole mode of its application being by framed trusses, upon the same principles as those usually employed for roofing.

These considerations induced Mr. John Green, as far back as the year 1827, to make a design and model for a bridge, with timber arches resting upon stone piers. In 1833 the plan was adopted, and in 1837 it was put into execution at the Ouse Burn Viaduct, where the construction was of great extent, and the cost was an important consideration.

The Viaduct is 918 feet in length, and 108 feet in height from the bed of the river. There are five arches, the versed sine 33 feet, and the radius 68 feet; three of them are 116 feet span each, and two are 114 feet each: two stone arches of 40 feet span each have been introduced at each end to give length to the abutments, and to prevent the embankments from being brought too near to the steep sides of the ravine. The piers are of stone: the springing stones for the three ribs, of which each arch is composed, are on offsets, within 40 feet of the top of the piers; cast-iron sockets are there bedded in the masonry, and secured so as to receive the feet of the ribs. Two of the piers are placed upon piles; the others are founded upon the rock: immediately beneath the centre of one of them an old coal-pit shaft was discovered, and close adjoining to it the remains of the working of a coal seam: both were rendered secure by being filled up with grouted rubble masonry.

The ribs for the arches are composed of planks of Dantzic deal (Kyanized): the lengths vary from 46 feet to 20 feet, by 11 inches wide and 3 inches thick: they are so disposed, as that the first course of the rib is two whole deals in width, the next is one whole and two half deals, crossing the joints longitudinally as well as in the depth. Each rib consists of fourteen deals in thickness, bent over a centre to the required form, and secured together by oak treenails 1¼ inch diameter at intervals of 4 feet apart, each treenail traversing three of the deals. A layer of strong brown paper dipped in boiling tar is placed between the joints, to bed them and exclude the wet. Trussed framings and beams are secured upon the arched ribs; the platform composed of planks, each 11 inches wide by 3 inches thick, is spiked down and covered with a composition of boiling tar and lime mixed with gravel in laying on, forming a coating impervious to the wet; upon this platform the two lines of railway are laid, leaving a foot-path between them.

The centreing for turning the ribs was very light and simple, and as every convenience was afforded by having a railway with travelling cranes along the sides of the piers, a whole centre could be moved by twenty men from one arch, and fixed in another in one day.

The author then describes the construction of the Wellington Viaduct, and that which has been erected by him at Dalkeith for the Duke of Buccleuch; giving the relative costs of the three structures which have been mentioned, and stone buildings of the same dimensions: whence it appears that in the Ouse Burn Viaduct there was an economy of £9000, resulting from the adoption of this system.

He then shows the application of this system to the structure of oblique bridges, particularly where a certain clear space is required beneath, and the total height is limited: this is illustrated by a description of a bridge of 71 feet span, on the Newcastle and North Shields Railway, which crosses the turnpike road at Walker, and by one erected over the River Wear on the West Durham Railway.

He describes also the application of the same system to the extensive buildings and sheds of the Shields Railway Station; to churches and to private houses; in the latter the arched form is very advantageous in gaining space for the upper rooms, showing at the same time the economy resulting from the adoption.

The paper is illustrated by a series of nine elaborate detailed drawings, showing the application to every kind of construction.

Mr. Rendel remarked, that on those railways where first cost was a matter of importance, the introduction of a superior kind of Timber Bridge was a great desideratum. The communication proposed the application of tarred paper between the joints, from experience he could not recommend either paper or felt in such situations. He found that both substances prevented the intimate contact of the surfaces of the timber; in all framings exposed to the action of the weather the tar was absorbed by the wood; the paper and felt then became saturated with and retained the moisture, so that decay very speedily ensued. The mode he at present adopted was to have all the joints and mortices of the framings very closely fitted, leaving only sufficient space at the edges to be caulked with oakum, and the joint run with pitch, like the seams of the deck of a vessel. Wherever it was practicable, great advantage would result from covering the joints with sheet lead, to exclude the moisture and prevent the decay, which was the great bar to the more general use of timber in many engineering works.

Mr. Vignoles was inclined to think the curve of the arch was too steep; he should prefer its being flatter. He would not then enter into the subject, but he would present to the Institution a large model of a Timber Bridge, and with it a communication, explaining his views on this subject, which was one to which he had paid much attention.

Mr. Macneil had found constant trouble to result from the decay of wooden bridges. The Dalmarnoch Bridge, which had been erected about thirty years, now demanded continual repairs; the struts were nearly all decayed at the points of insertion into the cast-iron sockets. The original floor had been replaced by one of teak wood.

In answer to a question from the President as to the process of "Kyanizing" timber for the Hull and Selby Railway, Mr. Timperley described the method pursued there. In a close cylindrical wrought-iron vessel, 70 feet long and 6 feet diameter, filled with a solution of corrosive sublimate, the timber was piled, leaving a space along each piece; the air was then exhausted by air-pumps to a vacuum of about 25 inches by the mercury gauge, and by the application of a force-pump, under a pressure of 100 lb. per square inch, the solution was driven into the pores of the timber. From experiments be had made he believed that the timber was thus thoroughly saturated, and although sufficient time had not elapsed to give any correct result as to the comparative duration of the sleepers, he thought very favourably of the process.

The original cost of the timber, which was the best Riga Balk, squared, was 5*l.* 10*s.* per load (50 cubic feet). The expense of "Kyanizing" about 400,000 cubic feet, including the interest of the first cost of the apparatus, was between fourpence and fivepence per cubic foot. The process was carried on with greater rapidity, and much more effectually, than it could have been done in open tanks.

Mr. Lowe was of opinion, that although the mechanical part of this process appeared very effective, it was not really so. There were chemical difficulties: a certain length of time was required to dilute and extract the sap and aqueous matter from the pores. The greater or less duration of the process might in some measure account for the difference of the results practically obtained. Dry planks succeeded better than wet ones; with sound dry timber any solution of the metallic salts, such as the sulphates of iron or copper, was efficacious, but with wet timber he doubted whether any preparation would be effectual.

Mr. Cooper believed that in the process of "Kyanizing" the chlorine united with the albumen, and formed chloride of albumen; it was possible that in the exhausting process the air contained in the timber would expand and prevent the capillary tubes from becoming perfectly saturated with the solution of corrosive sublimate.

March 16.—The PRESIDENT in the Chair.

John Hambley Humfrey was elected an Associate.

"*Description of the Methods adopted for raising and sustaining the sunken Roof of St. George's Church, Dublin.*" By Robert Mallet, Assoc. Inst. C. E.

St. George's parish Church, one of the finest ecclesiastical edifices in the city of Dublin, was completed in the year 1802, from the designs of the late Francis Johnston, Architect to the Board of Works at that time, at a cost of about £90,000.

The church had not been built many years, before the roof, which was covered with tun slating and copper, gradually sunk in several places, by which the cornices at the flank wall were pushed several inches outward. The subsidence slowly but continually increased. The ceiling cracked in various places, the ornamental stucco work began to drop off, and in the year 1836 the state of the roof was such, that the church was deemed unsafe for use, and was shut up.

Messrs. John and Robert Mallet were consulted as to the practicability of restoring the roof. In November, 1836, they reported that they considered the ceiling might be preserved, and described the manner in which they proposed to accomplish it.

The mode proposed consisted in interweaving with and adapting to the timber framing of the roof, a system of metallic framing, so arranged, that all strain or stress should be removed from the former, and borne by the latter, as well as removing all lateral pressure from the walls of the building.

A careful survey of the roof showed that the ends of several of the principals were unsound. A small hole was then bored through the ceiling, close to each queen-post, and a deal rod, ½ an inch square, dropped through each. These rods were all of equal length, and their upper ends were secured level with the top surface of the tye-beam of each principal; then with a levelling instrument placed in the gallery, observations were taken, and the exact amount of the deflection of the framing ascertained. The variation was considerable, but the greatest amount of depression was found to be 5½ inches. The whole roof was strained and distorted, and was so unsafe that the slightest effort caused vibration throughout.

The causes of this failure appeared to be threefold: a radical want of strength in the framing of the roof; secondly, the employment of unfit tye-beams, which having been constructed during the Continental war, when timber was scarce and dear, were formed almost wholly of short lengths, averaging not more than 20 feet, lapped and scarfed; thirdly, in the queen-posts having been badly constructed and ill placed.

The stone corbels, which supported the oak cantilevers, being originally cut almost through to receive the wall-plate, were nearly all broken in the middle. It was proposed, therefore, to remove the oak cantilevers and stone corbels, and to cut away the timber wall-plate beneath each principal, to level up the wall, placing a suitable cast-iron abutment piece at each end, and to spring from side to side a cast-iron arch, in "double flitches," connected through the spaces of the timber framing by hollow distance pieces, and also by a certain number of equidistant cross-heads, from which should drop down vertical suspending rods, capable of being adjusted in length, and connected with the tye-beam of the principal, so that being drawn up straight, and the respective parts secured, the weight of the whole roof would be transferred through the framing to the tye-beams; whilst they being hung from the system of suspension rods of the cast-iron arches, which would thus sustain the whole load, and their abutments being held together by the tye-bars in the chord line, the load would bear vertically upon the walls.

It was then determined to raise the roof and ceiling by forces applied from below; to cut away the rotten ends of the principals and to reconnect them with the walls by a modification of the cantilever bracket, invented by Mr. Alfred Ainger, and described in the Transactions of the Society of Arts (vol. 42). The whole of the oak cantilevers and stone corbels were to be removed as useless incumbrances.

The total weight of the roof being about 133 tons, each framed principal would sustain about 16¾ tons, and each vertical suspending rod about 1¼ ton.

Although the weight of material in this roof and ceiling may be considered uniformly distributed, it was impossible to foresee what change might be effected in the framing by forcing the ceiling and roof up to a level line, or what amount of force might bear upon particular points, from the elasticity of the materials being thus forcibly constrained. It hence became a matter of prudence to provide in all parts a large surplus of strength, bearing in mind that, in any complete system, "the strength of the whole is limited by that of the weakest part, and thus that partial strength becomes total weakness." The dimensions of the scantling were accordingly so calculated that the utmost strain upon it should not exceed 4·5 tons per square inch, considering 9 tons to be the practical limit to which wrought iron might be exposed.

After giving the formulæ for calculating the strains upon the different parts of the roof, with the reasons why the theoretical dimensions were in some instances departed from, the author apologises for entering so much into detail of the construction, quoting at the same time the writings of Smeaton and Telford, as abounding in the richest details of theoretic deduction, modified by practical judgment. He then proceeds to describe the means adopted.

Immediately beneath each of the fourteen queen-posts of the roof, an aperture of 30 inches square was cut through the floor of the church, and a piece of brick and cement built up from the arches of the vaults beneath to the level of the floor; on the top of each, a plate of cast iron was bedded, and upon each plate a block of oak timber about 4 inches thick.

Fourteen straight whole balks of Memel timber, each 3 feet shorter than the height of the church between the floor and the ceiling, with their extremities cut square and smooth, were placed vertically upon the blocks; upon this level a platform was laid; across the tops of the vertical balks, pieces of oak scantling were placed; fourteen powerful screw-jacks were then fixed, one beneath each queen-post, and the ceiling cut away for the points to bear directly upon the beams.

During the progress of these operations, the whole of the ceiling and roof framing had been carefully examined. The dust was removed from the joints and open mortices, &c., of the framing, and the cracks in the ceiling were cleared out by passing a fine whip saw through them, so as to permit their closing when the ceiling was raised to a plane surface.

The preparations being completed, the word was given to heave simultaneously upon the screw-jacks; the roof rose slowly and steadily, and as soon as any one of the small deal standard rods had reached the level plane, the motion of the screw-jack at that spot was stopped. In about two hours, the whole roof, together with the ceiling, was brought up level, without any accident or injury to any portion of the ceiling. The cracks in the latter as well as the joints and mortices of the framing were found to be nearly all closed. Some slates were broken, and the copper of the platform, which before was wrinkled and loose, was now found to be drawn tight over the timber sheathing.

The roof being thus supported from beneath, the masonry was cut out round the ends of the principals; the oak cantilevers and corbels of granite, and the rotten ends of the timbers, within a few inches of the inside face of the walls, were also removed.

The cantilever and abutment castings were now applied and bedded with lead and oil putty, on blocks of stone set at the level of the under side of the tye-beams, on footings of brick and cement. The chord bars were next placed, and temporarily adjusted by means of their screw nuts. The arch segments were put up in succession, their centre or key pieces bolted in, and the segments adjusted to them by means of wedges of African oak: the suspending rods were then hung on from the top shackles, and the junction made good with the tye-beams, by means of the lower cross-heads, stirrups, and shackles.

As soon as the whole system of the seven arched frames was complete, and the cantilevers adjusted to the ends of the decayed timbers, standing lengths of pine rods were placed in right lines from centre to centre of each pair of abutment cross bolts, and all the chord bars and suspending rods were brought up by means of their adjustment screws, until the united effort of the whole system had lifted and supported the entire roof and ceiling from the screw-jacks, on which they had previously rested, so that these latter all became loose.

The whole was now left quiet for some days, in order that every part might take its bearing, and that the sufficiency of the structure should be proved before the final removal of the screw-jacks, &c., which remained within about ¼ of an inch of the blocks beneath the tye-beams, by which means, in case of accident, the amount of fall would have been limited to that small distance. The entire work, including the repairing the cracks in the ceiling, occupied little more than four months, and has never since required either alteration or repair.

The total amount of the contract for this work was 1362*l.* 6*s.* The repair of the injury done to the ceiling only amounted to 33*l.* 0*s.* 8*d.*, and the damage done to the slating, platform, flooring, &c., did not amount to more than an equal sum.

The total amount of cast and wrought iron in the structure was 21 tons 10 cwt. 2 qrs. 19 lb.

The communication is illustrated by five elaborate drawings on a large scale, showing the general arrangement and modes of proceeding, and also the details of the construction of the roof and of the cast and wrought-iron works used in the repairs.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

July 5.—EARL DE GREY, President, in the Chair.

A paper was read by Professor Willis, of Cambridge, Hon. Mem. F.R.S. &c., *On the construction of the Vaulting of the Middle Ages.*

The vaulting of the Gothic architects differs essentially from that both of ancient and modern times, inasmuch as it consists of a combination of ribs, each forming an independent arch, both laterally and diagonally, with the intermediate spaces filled in upon the extrados of the arches to form the spandrils, whereas, according to the ordinary system of vaulting, the whole is solid and keyed together. The principles of this latter mode of construction were first developed by Philibert de l'Orme, who, in his celebrated treatise, lays down the rules for drawing the vaults and setting out the voussoirs—but of the practice of the Gothic architects we have no account, and it remains to be inferred from an examination of their works. That they proceeded by geometrical methods there can be no doubt, though they were probably extremely simple, differing greatly in that respect from those expounded by Philibert de l'Orme. One thing to be especially observed in the plain vaultings of the middle ages is, that all the curves are segments of circles, the diagonals being struck from a centre below the springing of the lateral and cross ribs, and are contrasted in this respect with diagonals projected from the direct arches, according to the rule familiar to every carpenter, from which it results that all the points of a groined vault coincide, and will be touched by a straight line drawn from one end of such a range of vaulting to the other. To this mode of setting out the curves may be attributed the flagrant want of character which is apt to distinguish the modern imitations of Gothic vaulting, and it may even be observed in original examples, that the effect is less pleasing as this coincidence is more nearly approached. This is the case with vaultings executed after the four-centered arch came into fashion, in which, although the curves may not be projected, yet there is an approach to greater regularity from the springing of all the ribs being brought to one level. During the Norman period the drawing of the vaults is very rude, and we find it to have been frequently necessary to back up the extrados of the ribs in order to bring the spandrils into shape. In the succeeding period of our architecture more care was indispensable, on account of the greater complication of mouldings converging together at the springing, and the free and sketchy manner in which they are managed, and the superfluous mouldings got rid of before they overload the impost, is much to be admired, and is greatly superior to the method pursued in the 15th century, when the coverging ribs were all brought down to the impost, and died away into a mere bundle of reeds, of which the effect is exceedingly tame and uncharacteristic. Previously to the introduction of the last style of gothic vaulting, *fan groining*, various complicated figures were formed by the introduction of numerous cross ribs, but the mode of construction continued to be the same. The vaulting immediately preceding fan groining, which may, in fact, be considered as a transition style, Professor Willis designated as *stellar* groining, from the star shapes which usually enter into its composition, and it is remarkable, that in some cases this form is lost in execution, although laid down on the plan, the architect apparently not having calculated on the effect of perspective, whereas, in others, the artist has evidently depended upon it in order to bring out his design. At length, in fan groining, the compartments become so numerous that the system of separate ribs is abandoned, and the vaults are constructed according to the ancient and modern principle of cut stone. Professor Willis accompanied his lecture by an extensive display of drawings and models, illustrative of the geometrical system upon which he supposed the Gothic architects to have worked in producing these results.

After the lecture the noble President presented to Mr. Hall the medal of the Institute, which had been awarded for his essay on iron roofs.

July 19.—R. Wallace, Esq., in the Chair.

Henry Gally Knight, Esq., was elected an honorary member.

Mr. Hall's essay on iron roofs, to which the medal of the Institute had been awarded, was read.

This was the closing meeting of the session.

CALOTYPE.

The following account of some recent improvements in photography, by H. F. Talbot, Esq., was lately read before the Royal Society.

The author had originally intended, in giving an account of his recent experiments in photography, to have entered into numerous details with respect to the phenomena observed; but finding that to follow out this plan would occupy a considerable time, he has thought that it would be best to put the Society, in the first place, in possession of the principal facts, and by so doing perhaps invite new observers into the field during the present favourable season for making experiments. He has, therefore, confined himself at present to a description of the improved photographic method, to which he has given the name of *Calotype*, and reserves for another occasion all remarks on the theory of the process. The following is the method of obtaining the Calotype pictures.

Preparation of the Paper.—Take a sheet of the best writing paper, having a smooth surface and a close and even texture. The watermark, if any, should be cut off, lest it should injure the appearance of the picture. Dissolve 100 grains of crystallized nitrate of silver in six ounces of distilled water. Wash the paper with this solution, with a soft brush, on one side, and put a mark on that side whereby to know it again. Dry the paper cautiously at a distant fire, or else let it dry spontaneously in a dark room. When dry, or nearly so, dip it into a solution of iodide of potassium containing 500 grains of that salt dissolved in one pint of water, and let it stay two or three minutes in this solution. Then dip it into a vessel of water, dry it lightly with blotting-paper, and finish drying it at a fire, which will not injure it even if held pretty near; or else it may be left to dry spontaneously. All this is best done in the evening by candle-light. The paper so far prepared the author calls *iodized paper*, because it has a uniform pale yellow coating of iodide of silver. It is scarcely sensitive to light, but, nevertheless, it ought to be kept in a portfolio or a drawer, until wanted for use. It may be kept for any length of time without spoiling or undergoing any change, if protected from the light. This is the first part of the preparation of Calotype paper, and may be performed at any time. The remaining part is best deferred until shortly before the paper is wanted for use. When that time is arrived, take a sheet of the iodized paper and wash it with a liquid prepared in the following manner:—Dissolve 100 grains of crystallized nitrate of silver in two ounces of distilled water; add to this solution one-sixth of its volume of strong acetic acid. Let this mixture be called A. Make a saturated solution of crystallized gallic acid in cold distilled water. The quantity dissolved is very small. Call this solution B. When a sheet of paper is wanted for use, mix together the liquids A and B in equal volumes, but only mix a small quantity of them at a time, because the mixture does not keep long without spoiling. I shall call this mixture the *gallo-nitrate of silver*. Then take a sheet of iodized paper and wash it over with this gallo-nitrate of silver, with a soft brush, taking care to wash it on the side which has been previously marked. This operation should be performed by candle-light. Let the paper rest half a minute, and then dip it into water. Then dry it lightly with blotting-paper, and finally dry it cautiously at a fire, holding it at a considerable distance therefrom. When dry, the paper is fit for use. The author has named the paper thus prepared *calotype paper*, on account of its great utility in obtaining the pictures of objects with the camera obscura. If this paper be kept in a press it will often retain its qualities in perfection for three months or more, being ready for use at any moment; but this is not uniformly the case, and the author therefore recommends that it should be used in a few hours after it has been prepared. If it is used immediately, the last drying may be dispensed with, and the paper may be used moist. Instead of employing a solution of crystallized gallic acid for the liquid B, the tincture of galls diluted with water may be used, but he does not think the results are altogether so satisfactory.

Use of the Paper.—The Calotype paper is sensitive to light in an extraordinary degree, which transcends a hundred times or more that of any kind of photographic paper hitherto described. This may be made manifest by the following experiment:—Take a piece of this paper, and having covered half of it, expose the other half to daylight for the space of *one second* in dark cloudy weather in winter. This brief moment suffices to produce a strong impression upon the paper. But the impression is latent and invisible, and its existence would not be suspected by any one who was not forewarned of it by previous experiments. The method of causing the impression to become visible is extremely simple. It consists in washing the paper once more with the gallo-nitrate of silver prepared in the way above described, and then warming it gently before the fire. In a few seconds the part of the paper upon which the light has acted begins to darken, and finally grows entirely black, while the other part of the paper retains its whiteness. Even a weaker impression than this may be brought out by repeating the wash of gallo-nitrate of silver, and again warming the paper. On the other hand, a stronger impression does not require the warming of the paper, for a wash of the gallo-nitrate suffices to make it visible, without heat, in the course of a minute or two. A very remarkable proof of the sensitiveness of the calotype paper is afforded by the fact stated by the author, that it will take an impression from simple moonlight, not concentrated by a lens. If a leaf is laid upon a sheet of the paper, an image of it may be obtained in this way in from a quarter to half an hour. This paper being possessed of so high a degree of sensitiveness, is therefore well suited to receive images in the camera obscura. If the aperture of the object-lens is one inch, and the focal length fifteen inches, the author finds that *one minute* is amply sufficient in summer to impress a strong image upon the paper of any building upon which the sun is shining. When the aperture amounts to one-third of the focal length, and the object is very white, as a plaster bust, &c., it appears to him that *one second* is sufficient to obtain a pretty good image of it. The images thus received upon the Calotype paper are for the most part invisible impressions. They may be made visible by the process already related, namely, by washing them with the gallo-nitrate of silver, and then warming the paper. When the paper is quite blank, as is generally the case, it is a highly curious and beautiful phenomenon to see the spontaneous commencement of the picture, first tracing out the stronger outlines, and then gradually filling up all the numerous and complicated details. The artist should watch the picture as it developes itself, and when in his judgment it has attained the greatest degree of strength and clearness, he should stop further progress by washing it with the fixing liquid.

The fixing process.—To fix the picture, it should be first washed with water, then lightly dried with blotting paper, and then washed with a solution of bromide of potassium, containing 100 grains of that salt dissolved in eight or ten ounces of water. After a minute or two it should be again dipped in water and then finally dried. The picture is in this manner very strongly fixed, and with this great advantage, that it remains transparent, and that, therefore, there is no difficulty in obtaining a copy from it. The calotype picture is a negative one, in which the lights of nature are represented by shades; but the copies are positive, having the lights conformable to nature. They also represent the objects in their natural position with respect to right and left. The copies may be made upon Calotype paper in a very short time, the invisible impressions being brought out in the way already described. But the author prefers to make the copies upon photographic paper prepared in the way which he originally described in a memoir read to the Royal Society in February 1839, and which is made by washing the best writing paper, first with a weak solution of common salt, and next with a solution of nitrate of silver. Although it takes a much longer time to obtain a copy upon this paper, yet, when obtained, the tints appear more harmonious and pleasing to the eye; it requires in general from three minutes to thirty minutes of sunshine, according to circumstances, to obtain a good copy on this sort of photographic paper. The copy should be washed and dried, and the fixing process (which may be deferred to a subsequent day) is the same as that already mentioned. The copies are made by placing the picture upon the photographic paper, with a board below and a sheet of glass above, and pressing the papers into close contact by means of screws or otherwise. After a calotype picture has furnished several copies, it sometimes grows faint, and no more good copies can then be made from it. But these pictures possess the beautiful and extraordinary property of being susceptible of revival. In order to revive them and restore their original appearance, it is only necessary to wash them again by candle-light with gallo-nitrate of silver, and warm them; this causes all the shades of the picture to darken greatly, while the white parts remain unaffected. The shaded parts of the picture thus acquire an opacity which gives a renewed spirit and life to the copies, of which a second series may now be taken, extending often to a very considerable number. In reviving the picture it sometimes happens that various details make their appearance which had not before been seen, having been latent all the time, yet nevertheless not destroyed by their long exposure to sunshine. The author terminates these observations by stating a few experiments calculated to render the mode of action of the sensitive paper more familiar. 1. Wash a piece of the iodized paper with the gallo-nitrate; expose it to daylight for a second or two, and then withdraw it. The paper will soon begin to darken spontaneously, and will grow quite black. 2. The same as before, but let the paper be warmed. The blackening will be more rapid in consequence of the warmth. 3. Put a large drop of the gallo-nitrate on one part of the paper, and moisten another part of it more sparingly, then leave it exposed to a very faint daylight; it will be found that the lesser quantity produces the greater effect in darkening the paper; and in general, it will be seen that the most rapid darkening takes place at the moment when the paper becomes nearly dry; also, if only a portion of the paper is moistened, it will be observed that the edges or boundaries of the moistened part are more acted on by light than any other part of the surface. 4. If the paper, after being moistened with the gallo-nitrate, is washed with water and dried, a slight exposure to daylight no longer suffices to produce so much discoloration; indeed it often produces none at all. But by subsequently washing it again with the gallo-nitrate and warming it, the same degree of discoloration is developed as in the other case (experiments 1 and 2). The dry paper appears, therefore, to be equal, or superior in sensitiveness to the moist; only with this difference, that it receives a virtual instead of an actual impression from the light, which it requires a subsequent process to develope.

Plaster Ornaments.—The late Mr. Bernasconi was engaged, we believe, to a greater extent than any other ornamental plasterer of the present century, under all the leading architects of the day. We were lately induced to pay a visit to his former scene of business, in Alfred Street, Tottenham Court Road, now in possession of Mr. Brown, his son-in-law, who has lately arranged the numerous ornaments bequeathed him by the late possesor. They are well deserving of a visit by the architect; here he will find Grecian, Roman, Gothic, Elizabethan, the Renaissance, Arabesque, and almost every other style of ornaments that have been introduced at Windsor Castle, Buckingham Palace, Pavilion Brighton, Stafford House, Westminster Abbey, Fonthill, Woburn Abbey, York Minster, Ely Cathedral, and numerous other public buildings and mansions throughout the United Kingdom.

MISCELLANEA.

WESTMINSTER BRIDGE.

On Thursday, 15th ult., the water was admitted into the coffre-dam inclosing the 15th and 16th piers, and the next day a commencement was made in removing the clay preparatory to drawing the piles. It is intended to open two arches for navigation before any further steps are taken with the next dam, which is to enclose one pier only. A deep water channel is now in progress of being made on the north side of the river, in line with the two arches about to be opened, by a steam dredging engine, for the use of navigation The present neglected state of the river not only interferes most injuriously with the interests of those who navigate it, but causes the velocity of the current at the latter part of the ebb to be greater than is consistent with safety to the number of small boats and inexperienced persons frequenting the river at this season of the year. It is, therefore, a consummation much to be desired, that a subject so important to the welfare of this great metropolis should receive the attention it deserves, and that the city authorities, aided by government, will yet be able to carry into effect either their former scheme of embanking the river to a more regular line, or some modification of this plan by which the present evils may be removed, so that this noble river may again be restored to its former usefulness.

OPENINGS OF RAILWAYS.

The thirtieth of June witnessed a great extension of the Great Western Railway, as on that day the main line was opened from Chippenham to Bath, 13 miles, the Cheltenham and Great Western to Cirencester, and the Bristol and Exeter from Bristol to Bridgewater, 33 miles. Thus the Great Western Railway is opened throughout 118¼ miles, and there is a continuous line of railway communication from London to Bridgewater of 152 miles in length.

On the 5th of July 28¼ miles of the Brighton line were opened, being from the Croydon Junction to Hayward's Heath, and 5 miles from Clayton Tunnel to Brighton, a measure which augurs well for the successful opening of the remainder.

The extension of the Blackwall railway to Fenchurch Street was to take place about the period of our publication, so that all the metropolitan railways would thus be complete at their London termini.

The unfortunate accident to the Fareham tunnel on the Gosport branch of the South Western Railway, has unfortunately delayed the opening of that line, just when it was on the point of being examined by the Government inspector.

GREENWICH RAILWAY.

Amounts of the tenders delivered on the 6th ult. for the fourth contract for widening the Greenwich Railway from the Croydon Junction.

Messrs. Lee	15.825
Mr. Munday	15.990
Messrs. Little	16.189
Mr. Grimsdell	16.536
Messrs. Ward	16,698
Mr. Bennett	16,920
Messrs. Piper	16.920
„ Grissell & Peto	17.280
„ Baker	17,440

THE "PRINCESS ROYAL" STEAMER.

This splendid vessel. which appears to surpass the speed of any other in the north, is now running between Liverpool and Glasgow, and has made several successful trips; she performed a trip from Dublin to Liverpool in 9 hours, and another trip on the 9th ult. from Greenock to Liverpool in 15¼ hours, the quickest passage on record. the distance is 227½ miles; she carried at the time 100 tons actual weight. Both the vessel and engines were built by Messrs. Tod & Macgregor of the Clyde Foundry, Glasgow. the former is of the following dimensions, viz., 185 feet keel and 208 feet on deck, 28 feet beam, and 17 feet hold above the flooring, draws when light 8 feet, and when full 10 feet of water; her register is 750 tons (N.M.). She is entirely built of iron, (there is not a single beam of wood,) very strong, and has a fine appearance in the water, her cabins are very richly and tastefully fitted up. The vessel is propelled by two steeple or upright engines of 190 horse power each, or 380 together; the power is applied direct to the crank. Diameter of cylinders is 73 inches, length of stroke 6 ft. 3 in., performs 18 strokes per minute when in good trim, and 17 strokes with from 100 to 120 tons of cargo, diameter of paddle-wheel over floats 29 feet length of float 7 ft. 9 in., and breadth 28 inches, speed in still water 15 miles per hour.

Launch of the Devastation War Steam-vessel.—The launch of this first-class war steam-vessel took place at Woolwich, on Saturday, 3rd ult. Mr. Lang, master shipwright. superintended the launch; she was immediately after hauled into the dock, opposite the blacksmith's workshop, where she will be coppered, and will be afterwards taken into the basin to have her engines fitted and made ready for sea. The Devastation is about 180 feet long, and about 1,050 tons burden, old measurement. or about 1,000 tons burden according to the new mode of calculation.

The Cadogan Chain Pier, Chelsea.—Earl Cadogan, the lord of the manor, has erected a handsome and convenient pier for steam-boat passengers on a novel construction, at an expense of between £3,000 and £4,000. This erection was constructed by Mr. Cubitt, from the design and under the direction of Mr. Handford, the surveyor and architect of the manor. The pier is situated in the mall of Cheyné-walk, the most beautiful part of Chelsea, and forms one of the most interesting objects of the place. Shortly the pier will be open to the public.

Professor Wagner's Electro-Magnetic Engine.—The German journals publish the following extract from a protocol drawn up by the Germanic Diet:—"The Germanic confederation desiring to acquire, for the purpose of publishing for the public good, the secret by means of which citizen Philip Wagner, of Frankfort, makes use of electro-magnetism as a moving force, will secure to the said Wagner for the exclusive possession of his secret the sum of 100,000 florins (£8,000 British), on condition that he cause an electro-magnetic machine to be constructed at his own expense, and upon a sufficiently large scale, to serve as a locomotive; that a trial be made of this machine, in order that the diet be assured of its efficacy; and that M. Wagner consented to abide by the decision of the Diet on that trial. The Diet will wait for one month for M. Wagner to accept those conditions.

Land-slip at Sidmouth.—A land-slip of considerable extent took place at Sidmouth on the 11th ult., about seven in the evening. It commenced about half-past six by a rumbling noise, resembling a distant peal of thunder, and at seven o'clock part of the Peak Hill was observed to glide towards the ocean, carrying everything before it, and forming a rock or pillar out of the sea (70 feet high and 175 feet in circumference), opposite to the town, and a quarter of a mile from the shore. It is covered with fossils, and is of a hard iron-like substance. So singular an occurrence has attracted the attention of every one in the town, and hundreds are flocking from the immediate neighbourhood to gain a sight of its results.—*Dorset Chronicle.*

The Dissolving Views at the Royal Polytechnic Institution.—The directors of this scientific institution, ever seeking to combine amusement with instruction, have recently added to their numerous attractions an entirely new series of dissolving views by Messrs. Wrench & Smith, which, for selection of subjects and the artistic feeling with which they are treated, may be considered unquestionably the best of the kind hitherto exhibited: there are sixteen in number, and if we may judge from the gratification evinced by the numerous company who attend upon each occasion that these beautiful views are shown, the spirited proprietors cannot but congratulate themselves upon having secured such to an exhibition, which is and must doubtless become an increasing attraction to this institution.

LIST OF NEW PATENTS.

GRANTED IN ENGLAND FROM 28TH JUNE, TO 28TH JULY, 1841.

Six Months allowed for Enrolment.

John Chater, of the Town of Nottingham, machine-maker, and Richard Gray, of the same place, lace manufacturer, for "*improvements in machinery for the purpose of making lace and other fabrics, traversed, looped, or woven.*" —Sealed June 26.

Willoughby Methley and Thomas Charles Methley, of Frith-street, Soho, ironmongers, for "*improvements in machinery for raising, lowering, and moving bodies or weights.*" (A communication.)—June 26.

Moses Poole, of Lincoln's-inn, gentleman, for "*improvements in producing and applying heat.*" (A communication.)—June 26.

William Losh, of Little Benton, Northumberland, Esq., for "*improvements in the manufacture of railway wheels.*"—June 26.

Nathaniel Benjamin, of Camberwell, gentleman, for "*improvements in the manufacture of type.*" (A communication.)—June 28.

William Knight, of Durham-street, Strand, gentleman, for "*an indicator for registering the number of passengers using an omnibus or other passenger vehicles.*"—June 28.

Christopher Nickels, of York-road, Lambeth, gentleman, for "*improvements in the manufacture of mattresses, cushions, paddings or stuffings; and in carpets, rugs, or other napped fabrics.*"—June 28.

William Thomas Berger, of Upper Homerton, gentleman, for "*improvements in the manufacture of starch.*"—June 28.

Thomas Marchell, of Soho-square, surgeon, for "*improvements in raising and conveying water and other fluids.*"—June 28.

George Henry Phipps, of Deptford, engineer, for "*improvements in the construction of wheels for railway and other carriages.*"—July 2.

Thomas Hagen, of Kensington, brewer, for "*an improved bagatelle board.*" —July 7.

George Onions, of High-street, Shoreditch, engineer, for "*improved wheels and rails for railroad purposes.*"—July 7.

Robert Mallet, of Dublin, engineer, for "*certain improvements in protecting cast and wrought iron and steel, and other metals, from corrosion and oxidation; and in preventing the fouling of iron ships, or ships sheathed with iron, or other ships or iron buoys, in fresh or sea water.*"—July 7.

William Edward Newton, of Chancery-lane, civil engineer, for "*certain improvements in the manufacture of fuel.*" (A communication.)—July 7.

Thomas Fuller, of Bath, coachmaker, for "*certain improvements in retarding the progress of carriages under certain circumstances.*"—July 7.

Andrew M'Nab, of Paisley, North Britain, engineer, for "*an improvement or improvements in the making or construction of meters or apparatus for measuring water or other fluids.*"—July 7.

Charles Wheatstone, of Conduit-street, gentleman, for "*improvements in producing, regulating, and applying electric currents.*"—July 7.

John Steward, of Wolverhampton, Esq., for "*certain improvements in the construction of piano fortes.*"—July 7.

Thomas Young, of Queen-street, London, merchant, for "*improvements in lamps.*"—July 9.

Charles Payne, of South Lambeth, chemist, for "*improvements in preserving vegetable matters where metallic and earthy solutions are employed.*" July 9.

William Henry Phillips, of Manchester-street, Manchester-square, civil engineer; and David Hichinbotham, of the same place, gentleman, for "*certain improvements in the construction of the chimneys, flues, and air tubes, with the stoves, and other apparatus connected therewith, for the purpose of preventing the escape of smoke into apartments, and for warming and ventilating buildings.*"—July 13.

Benjamin Beale, of East Greenwich, engineer, for "*certain improvements in engines, to be worked by steam, water, gas, or vapours.*"—July 13.

Moses Poole, of Lincoln's-inn, gentleman, for "*improvements of steam baths, and other baths.*" (A communication.)—July 13.

Miles Berry, of Chancery-lane, civil engineer, for "*improvem nts in the construction of locks, latches, or such kind of fastenings for doors and gates, and other purposes to which they may be applicable.*" (A communication.)—July 14.

Thomas Peckston, of Arundel-street, Strand, Bachelor of Arts, and Philip Le Capelain, of the same place, coppersmith, for "*certain improvements in meters for measuring gas, and other aeriform fluids.*"—July 15.

Andrew Smith, of Belper, Derby, engineer, for "*certain improvements in the arrangement and construction of engines, to be worked by the force of steam, or other fluids; which improved engines are also applicable to the raising of water and other liquids.*"—July 21.

John M'Bride, manager of the Nursery Spinning Mills, Hutchisontown, Glasgow, for "*certain improvements in the machinery and apparatus for dressing and weaving cotton, silk, flax, wool, and other fibrous substances.*"—July 21; four months.

John White Welch, of Austin-Friars, merchant, for "*an improved reverberatory furnace to be used in the smelting of copper ore, or other ores which are or may be smelted in reverberatory furnaces.*"—July 21.

Frederick Theodore Philippi, of Belfield-hall, calico-printer, for "*certain improvements in the production of sal ammoniac, and in the purification of gas for illuminations.*" (A communication.)—July 21.

William Ward Andrews, of Wolverhampton, ironmonger, for "*an improved coffee pot.*"—July 21.

William Newton, of Chancery-lane, civil engineer, for "*certain improvements in machinery for making pins and pin nails.*" (A communication.)—July 28.

Anthony Bernhard Von Rathen, of Kingston-upon-Hull, engineer, for "*improvements in high-pressure and other steam-boilers, combined with a new mode or principle of supplying them with water.*"—July 28.

Anthony Bernhard Von Rathen, of Kingston-upon-Hull, engineer, for "*a new method or methods* (called by the inventor, 'The United Stationary and Locomotive System') *of propelling locomotive carriages on railroads and common roads, and vessels on rivers and canals, by the application of a power produced or obtained by means of machinery and apparatus unconnected with the carriages and vessels to be propelled.*"—July 28.

ERRATA.

Sir—In my communnication on "*Slopes in Sidelong Ground,*" in this month's (July) Journal, page 220, you will find the following misprints, which you will perhaps have the kindness to notice in your next publication.

For $(w \tan \beta - F L) = C F$, read $(w \tan \beta + h) = C F$.

For $C D = (w \tan \beta + h) \dfrac{\sin C F D}{\sin C E F}$, read $C D = (w \tan \beta + h) \dfrac{\sin C F D.}{\sin C D F}$

For $C E = (w \tan \beta + h) \dfrac{\sin C F D}{\sin C D F}$, read $C E = (w \tan \beta + h) \dfrac{\sin C F D}{\sin C E F}$.

For "therefore the angle C *D* F will be constant," read "therefore the angle C *F* D will be constant."

W. R.

In the review of Windsor Castle the following errors of the reviewer were passed unobserved until after the article had gone to press.

Page 278, col. 2, for Edward *the Third* called the Confessor, read Edward *the Confessor.*

In the 2nd paragraph, for Henry *III* read Henry *I.*

Page 279, col. 1, 3 lines from the bottom, for Henry 7 read Sir Reginald Bray. And in the last line, for *his* read *Henry VII.*

TO CORRESPONDENTS.

Mr. Barrett's *and* Mr. Brooks' *communications must stand over until next month; also the communications from* S. L. *and* D. C. *We must beg of our correspondents to excuse us in postponing any articles of controversy.*

"A clear fire." *In our opinion his scheme is not practicable.*

"On the forms and proportions of steam vessels," *was received as we were going to press; it will appear next month.*

Two communications on long and short connecting rods are in type, but must stand over until next month for want of space.

Communications are requested to be addressed to "The Editor of the Civil Engineer, and Architect's Journal," *No.* 11, *Parliament Street, Westminster.*

Books for Review must be sent early in the month, communications on or before the 20th (if with drawings, earlier), and advertisements on or before the 25th instant.

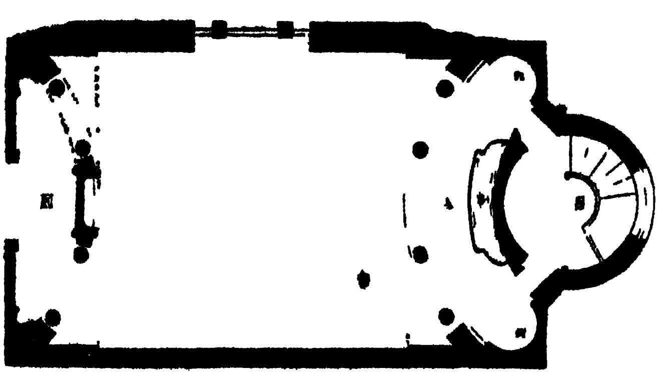
Vols. I, II, and III, may be had, bound in cloth, price £1 each Volume.

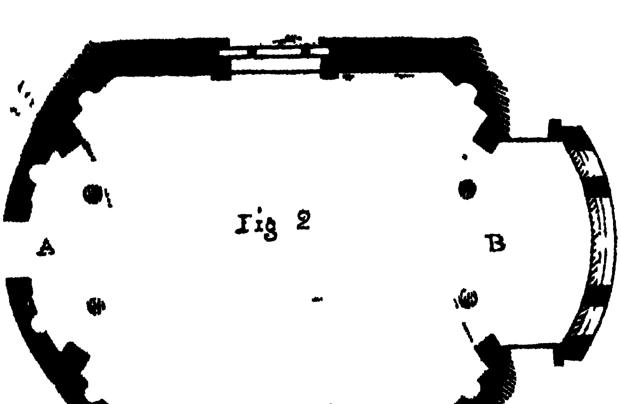
EPISODES OF PLAN.

(Continued from page 148.)

We should be less embarrassed by the extent and complexity of our subject, could we command an unlimited number of cuts to illustrate it; but being under the necessity of observing economy in that respect, and to confine ourselves to *floor-plans* alone, without attempting to show anything further, we experience no little difficulty in determining what sketches to give in preference, out of the ample stock of our materials. Under such circumstances it will perhaps be expected that we should select such as bear the least resemblance to each other; yet, by so doing, we could not show how the same leading idea may, by some slight modification of it, be so altered as to produce a room of quite different character. Which last consideration induces us to give a second plan for a dining-room, bearing a strong resemblance to the preceding one in its general shape and arrangement, yet greatly varied from it with respect to many other circumstances. Therefore, in order that the two may be more conveniently compared together, we will here again introduce the first one, which was but indifferently printed when originally given.

Fig 1



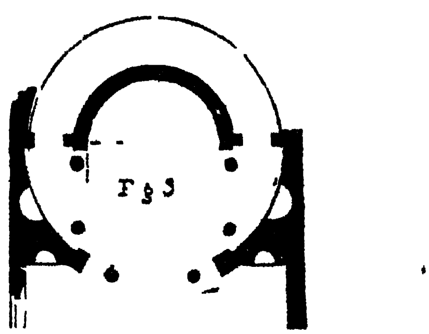


Owing to the peculiarity or singularity of both these ideas, the resemblance between them will probably be thought far more striking than the difference, since the second one also shows a room whose ends are convex in plan, and which is otherwise very similarly arranged. The situation here given to the fire-place would be in itself too trifling a variation to call for notice, were it not that it materially alters the character of the whole, by leaving the entrance recess entirely open to the room; and in consequence, the elevation of that end becomes precisely similar to the opposite one, each of them presenting three open intercolumns, formed in this instance merely by a distyle in antis, consequently with two columns less than in the other plan. A more important distinction is that in this second plan the corners of the room are cut off, whereby not only is the somewhat objectionable sharpness of the angles, occasioned in the other instance by the curved ends being brought up to the side walls, avoided, but the proportion which the end elevation bears to the entire breadth of the apartment is also altered. Besides which, four niches, placed diagonally on the plan, are thus obtained, where they would seem to come in with great propriety—conspicuously, but not obtrusively; on the contrary, where they are in some measure required in order to fill up, and give importance to those spaces. For the last assigned reason, niches are likewise introduced into the entrance recess A.

Should it be made an objection that in consequence of its forming two intersecting curves in its plan, the part A would either occasion much space to be lost, or render it difficult to connect this apartment with an adjoining one, it may be got over by converting the curved wall in which the door is placed into a flat one. Such alteration would still leave the rest of the design just the same as before; nevertheless its character would in some degree be affected by it, and that for the worse, if only because the uniformity now kept up, by the smaller recess A being curved both ways similarly to the larger one B, would then be destroyed. How far the circumstance here noticed would create difficulty by interfering too much with the general plan of the house, must depend upon what would be altogether foreign from our present purpose to take into consideration; our object here being merely to suggest new ideas, and bring forward episodical portions of a plan, not to adapt them to plans in general. We leave the particular application of them to others, leaving also those who may care to adopt any of our hints to adapt and modify them accordingly as circumstances may require, for what would be found eligible and convenient enough in one case, would prove exactly the contrary in another. A remark to the same effect has, we find, already been made by us, nevertheless it is one that will very well bear to be repeated, as it is likely to be forgotten by others, though it is highly important that it should be constantly borne in mind by our readers.

The sideboard alcove B does not call for much explanation or comment, we shall therefore confine ourselves to saying that the same accommodation is here afforded as in the first plan, namely an entrance into it for servants. Though two doors are shown, one of them would be sufficient for the purpose, and the other might either be a sham one, or should the plan allow of its being done, might be made to lead to a strong closet for containing the more valuable articles of plate, and also a small retiring closet, &c. The window in this alcove is supposed to be at a considerable height from the floor—eight or nine feet—as the sideboard would be placed beneath it; and it is intended merely to obtain some light from a back court or area, for which reason it should have coloured or ground glass, but merely of such hue as would be sufficient to correct rawness of effect, and throw a sunshiny glow into that end of the room. Though it is differently represented in the cut (fig. 2), it would perhaps be better to confine this window to what now forms its centre compartment (corresponding in breadth with the centre intercolumn of the alcove), treating it as an oblong transparent panel, slightly sunk in the upper part of the wall.

We will now submit another idea professing to be no more than a variation of the alcove capable of being adapted to either of the preceding plans; for which reason it is unnecessary to show the whole of the room in the cut.



In this instance the alcove is greatly extended as to depth, more especially as compared with that in fig. 1, from which, indeed, it is altogether dissimilar, because there not only is the recess considerably shallower, but its back wall is curved convexly, and concentrically with the elevation towards the room. At the same time it resembles fig. 1, in so far as it occupies the entire width of the room; but then again, such resemblance is attended with a very material difference, inasmuch as in fig. 3, the alcove is more enclosed, so that it seems to expand itself within, as viewed through the external columns. The same may be said of it, if it be compared with fig. 2, that being a simple recess merely divided off from the room by columns, and no wider within than its opening towards the room.

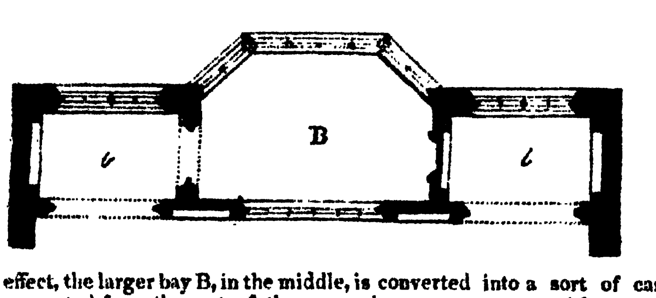
Fig. 3, on the contrary, affords an example of what may very well be distinguished by the name of a *compound* recess,—and also of what many will, no doubt, be apt to consider a strangely fanciful—not to say fantastical, arrangement. We certainly cannot produce authority for any thing of the kind, because we do not recollect, and therefore may safely affirm that we have never met with any similar instance. If others choose to say, it ought on that very account, to be received with a good deal of suspicion, they are certainly at liberty to do so—or for that matter, to reject our ideas and opinions altogether.

Capricious as it may at first sight be considered, this alcove (fig. 3), will, we think be found, on examination, to be well motived and commodious in plan. While the inner columns would produce great richness of effect—would render the whole a striking architectural picture; they serve also to define the central space, to keep that part more distinct from the rest, thereby giving more importance to that, and by screening off the spaces behind them, to convey the idea of the alcove's being greatly extended by the addition of these last. Nor is it in such respect alone that the plan belongs to the class we would distinguish as compound, since such character is still further increased by the addition it receives from the part *s*, which is here made to form a second or inner recess where the sideboard would be placed, and which therefore should be allowed to show itself distinctly as such by being treated as a large niche, or else covered with a semidome carried up above the ceiling of the alcove and room. In the last mentioned case, that recess might be lighted from above through its dome, nor would other light be then required; should that however, not be practicable, and should an arched niche-like recess also be objected to for the design, it would then be better to contract the space *s*, reducing it from a semicircle to a more shallow recess whose curvature would be *anti-concentric* to, and therefore correspond with, that on which the columns facing it are placed,—as is done in the recess B, fig. 2.

Almost any one of these three plans above will be found, if studied for that purpose, to contain within itself the germs of many others; and notwithstanding that they possess something in common—taking them altogether they furnish more variety, as far as plan is concerned, than is now to be met with in as many thousand examples,—which however they may differ as to matters of decoration and detail are nearly alike in regard to arrangement and plan.*

Instead of proceeding, as we could easily do, with other plans of the same class, and for similar purposes, we will, by way of change, now exhibit one for the window side of a library, occupied entirely by three bays. In order both to obtain novelty of character, and increase picturesque

Fig. 4.



effect, the larger bay B, in the middle, is converted into a sort of case separated from the rest of the rooms, by an open screen with tracery, and carried down to about three feet from the floor. This screen, which might either be glazed or not, as should seem most expedient, would not only be characteristic and ornamental in itself, but be rather serviceable than otherwise, by moderating the light within the body of the room, and thereby rendering the two open bays, *b b*, more piquant and brilliant by contrast. In fact the plan would admit of the lower part of the screen being closed up to the height of about six feet from the floor, by which means additional space for book-shelves, on one if not both sides of it, might be obtained. And although this would materially diminish the light in that part of the room, little if any inconvenience would result from that circumstance, because it is here supposed that the room itself is chiefly intended to contain books, and that the cabinet B, and the two bays *b b*, would be for sitting in. Accordingly the fire-place is put within B, as the most convenient situation; and as that one would be sufficient, the space that must otherwise be occupied by a chimney-piece and chimney pier would be left free for book-cases or shelfing.

With the same plan, a room of very different appearance as to design, if not exactly as to character, might be produced by merely transposing the situation of the enclosed and open portions,—that is, by removing the screen between B and the room, and in lieu of it, screening off the two lesser bays *b b*, which might either immediately communicate with, and be open towards the larger bay, or entirely shut up from it, as one of them is shown in the cut. In the former case a vista would be obtained through the three bays, by a compartment at each end filled with a mirror, so as to give the effect of an open arch; or else instead of being filled with a single mirror, each of those compartments might be divided into panels by mullions, &c., like those of the screens, whereby the effect of an additional open screen in each of the smaller bays, might be obtained.

As our chief object is rather to afford suggestive hints, than to give plans definitively fixed, and intended for some one individual case, we do not pretend to enter into more exact description. The cut itself too, must likewise be received as a mere explanatory sketch, it being on too small a scale to admit of nicety as to detail, or do more than indicate the arrangement and principal forms.

(To be continued.)

* Should this be disputed, we should feel obliged to any one who would inform us what remarkable instances of the kind there are which would tend to support an opinion contrary to that here expressed.—Ed.

ON THE CONSTRUCTION OF OBLIQUE ARCHES.

SIR—I am sorry to trespass again on your pages in reference to Mr. Peter Nicholson's work on Railway Masonry, but having a few days since been made aware that a *second* edition of his book was published, in which a reference was made to some remarks I had previously written in your Journal, I procured a copy of it, and the reference in question being nothing more or less than a gross misrepresentation of facts, I trust you will allow me space to set the matter in its proper light.

The point in dispute is relative to Mr. Nicholson's trihedral system. In his first edition he says at page xxiii, "If a trihedral be cut by a plane perpendicular to one of its oblique edges, the section shall be a right angled triangle." Relating to this I made the remark that there were three sorts of trihedrals, and that this assumption only holds good with one of them, namely, a right trihedral.

In his second edition, page xxix. A, after stating that the trihedral there treated is a right trihedral, he says, "if *such* a trihedral be cut by a plane perpendicular to one of its oblique edges, the section shall be a right angled triangle." To the end of which he appends the following complimentary observation. "I have called this kind of trihedral a right trihedral; but a narrow-minded hireling, who signs himself W. H. B., in the Civil Engineer and Architect's Journal, page 152, has erroneously transcribed from a paragraph following, Def. 6, page xxiii., Railway Masonry, first edition, 'If a trihedral be cut by a plane perpendicular to one of its oblique edges, the section shall be a right angled triangle,' leaving out the part that would make sense. His remarks, founded on this mistranscription, resemble rather the puerilities of childhood, than the reasoning of mature age."

Setting aside his personal abuse which will neither benefit his position nor injure mine, the reply I have to make to the rest of his observation is, firstly, that in saying I have mis-quoted his work, he deliberately states that which he knows to be untrue; and there stands the paragraph at page xxiii., of the first edition to prove it.

Secondly. In saying I omitted the part that made sense of the passage, he accuses me of the very blunder he himself committed, of which the fact of his having corrected himself at page xxix. A, of the present edition, is abundant evidence.

The fact is, the page (xxix. A) is a fresh page which he has added to his book, for the express purpose of inserting the corrected paragraph; and has attached my remark to the corrected paragraph, declaring it to be a misquotation. It is really very lamentable to see a man of the standing Peter Nicholson once had, obliged to have recourse to so mean and unworthy a subterfuge; and it is still more lamentable to see him forget himself so much in the language he makes use of. I consider it to be the duty of every one who is in a position to do so, to expose the errors of a work addressed to the public; particularly when it comes from the pen of one who has enjoyed a considerable portion of their confidence and support, and is addressed to those classes who being unable to investigate the subjects contained in it for themselves, are compelled to rely implicitly on what is given to them by the author. With this view I made my remarks on Mr. Nicholson's first edition, and with this view I now proceed to show that a great deal yet requires alteration in the second.

Taking for example page 7, he says, "in order to prevent two joints from meeting each other, it is necessary that the number of arch stones in each face should be an odd number." Now every body at all ac-

Fig. 1.

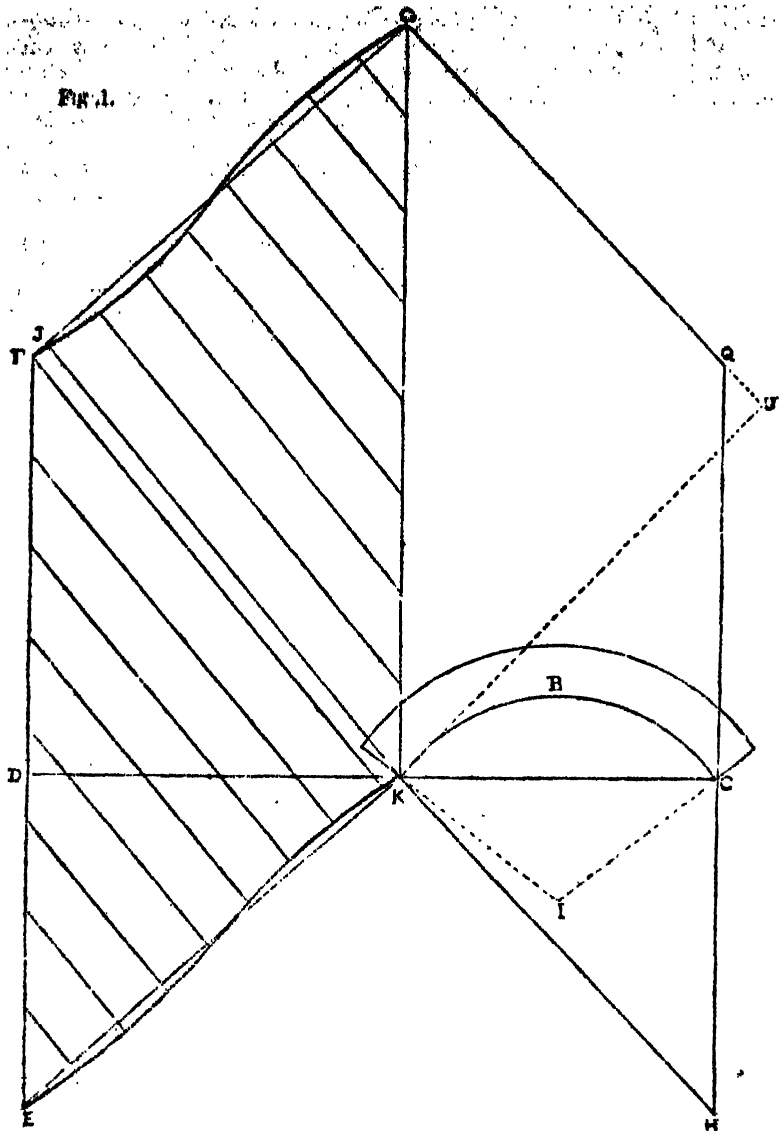


Fig. 3.

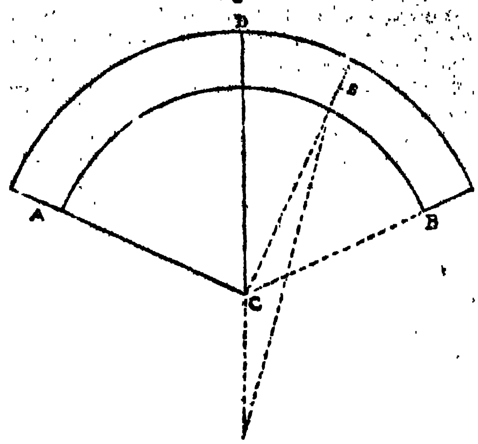

Fig. 4.

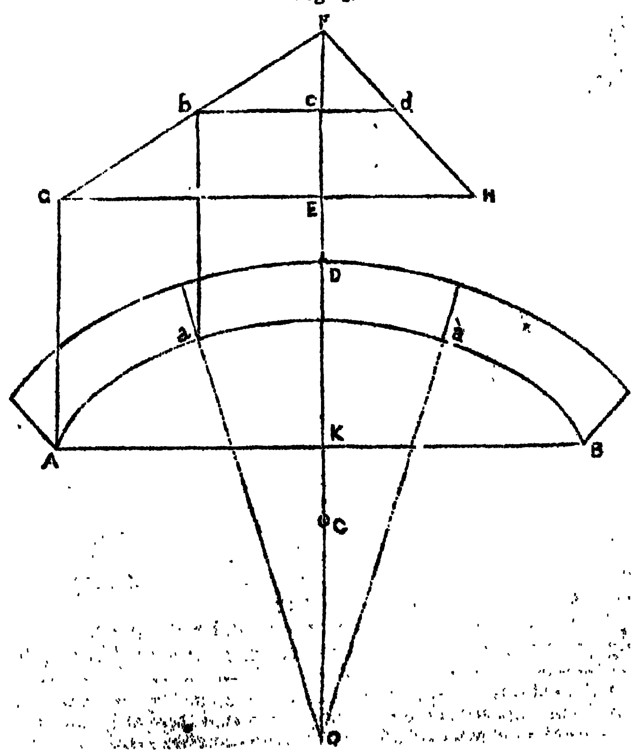
Fig. 2.



quainted with the subject knows that the number of courses being odd or even has nothing at all to do with the meeting of the joints.

Next, (referring to the same page), about dividing the line E A, fig. 1, we will here take a figure with his own letters as example, Suppose it was required to construct an oblique arch of the following dimensions, viz.:

Span 10 feet = A C.
Rise 2·5 feet.
Angle of obliquity 45° = A H C.
Width of bridge 16 feet = A u.

And take the case he does at page 7, in supposing the number of courses to be nine; following out the directions given by him, namely, to draw F K to meet the straight line A E perpendicularly in K, E K will be divided into eight courses, and A K will be the ninth; *which would require eight courses to be* 1 *foot* 10·17 *inches thick, and the remaining one to be* 6·86 *inches thick.* Now I would ask, does Mr. Nicholson really come forward with such a rule as this, and call his book a *Guide to ... Masonry?* Is he ignorant of the fact that Mr. Buck has surmounted this difficulty by the simple expedient of adjusting the angle of intrado—or is it that, rather than acknowledge his inferiority, he persists in what he knows to be wrong, and addresses his book to the working classes in the hope of escaping detection?

Again, with reference to obtaining the angles between the joint lines in the face and in the soffit of the arch. It is perfectly distressing to see a problem which admits of easy solution so miserably mutilated as it is in his hands. The construction given by him, that is to say the only one that deserves the name of an approximation, occupies two and a half closely printed pages of his book, while these angles may be obtained with much greater accuracy, and with about a quarter the labour as follows. Let A D B fig. 2 be the elliptical face of the arch, and O the point to which the joints in the face converge (see Buck on Oblique Bridges); produce O D to F any convenient distance, and make F E = half the obliquity of the arch. Draw G H parallel to A B, set off G E = A K, join G F, and draw the line F H, making the angle E F H equal the angle of extrado.

Then to find the curved bevel for any joint a, join a o, and draw a b and b d respectively parallel to O F and G H. Take two lines m n, o h, at right angles to each other, as at fig. 3, set off o v = d c, fig. 2, and from v, with a distance equal to a o, fig. 2, describe an arc intersecting o h at t. Then applying the mould of curvature of the spiral line of the intrado s t r, so that the line s' t r' drawn at right angles to o h, is a tangent to the curve at the point t; the angles s t v and r t v, are the bevels adapted for the joint a, fig. 2, and the corresponding joint a' on the other side of the arch. With this construction the angles for all the joints may be obtained from fig. 2, without any confusion in the figure.

These angles may also be obtained by computation, for let A D B, fig. 4, be the elevation of the arch on a plane at right angles to the axis of the cylinder, and C be its centre, and let a the position of any joint be given. The angle D C a being then known,

If the angle D C $a = \lambda$,
Angle of obliquity of arch $= \theta$,
Angle of extrado $= \varphi$,
And the radius of the cylinder $= r$.
Let r (cot. θ, sec. φ) $= a$,
And r (cot. θ, tan. φ) $= b$,

$$\frac{b}{a} = \text{tangent of the angle } v\ t\ o \text{ fig. 3.}$$

An oblique bridge however is not necessarily built of stone, nor has it always stone faces. Yet Mr. Nicholson would have the same interminable process gone through in every case, while if the arch be entirely of brick, and the span, the angle of obliquity, and the radius are given, all that is required for the workmen is the angle of skew-back, and the length of the check on the impost, which are at once obtained as follows:

Let θ = angle of obliquity,
s = square span,
a = length of arc,

$\frac{(\text{cot. } \theta)}{a} s = \text{tan. } \beta$, the angle of skew-back, and (cosec. β) 3 = length of the check in inches, 3 inches being the assumed thickness of a course of bricks. The length of the check thus obtained may be either adjusted so that each extremity of the impost coincides with the extremity of a check, or retaining the computed length of check, they may be so placed on the impost that the springing shall take place at the same elevation on both sides of the arch. After which if the courses are properly gauged on the centre, and the course lines drawn down to their respective checks, no mistake can arise in laying the bricks.

Mr. Nicholson's rules however are not only very unnecessarily tedious, but it would appear by his own showing, that they are not over certain in their results. In a note at the bottom of page 22, in reference to a model made by the joint assistance of two masons, a joiner, and Nicholson's Guide to Railway Masonry, he says, "N.B. the model here alluded to has only 16 spiral courses, although 17 were intended. However, the calculations in all the principal parts will remain the same." One course too many in sixteen is not much certainly, but in these economising times it is just as well, considering that it is just as easy to know before hand how many courses there are to be in a bridge. In whatever way however the alteration of the number of courses was produced, one thing is clearly showed by it, namely, the fallacy of his assertion at page 7, respecting the necessity of having an uneven number of archstones in the face.

As for all that part of his book which contains such problems as the following, viz.: "Given the three sides of a triangle to construct the triangle," and "from a given point near the middle of a straight line to draw a perpendicular;" it is, to say the least of it, most arrant twaddle. He might with equal propriety have added, given a pair of compasses with a point at one leg and a pencil at the other, to describe a circle.

However, I will say no more. For this time I have, as he observes, "done with him;" and I hope enough has been said to show Mr. Nicholson that his ideas have got a twist in their beds by no means adapted to skew-bridges, and that no species of brow-beating or invective on his part will be of the slightest use to him, while his book remains so very imperfect.

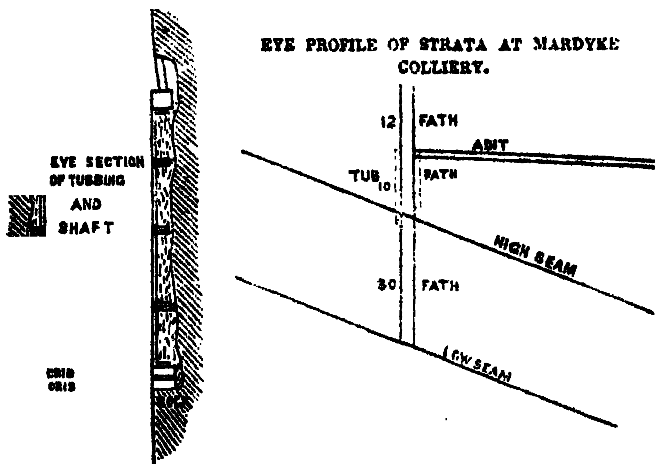
I am, Sir, your obedient servant,
W. H. BARLOW.

Brereton, August 16, 1841.

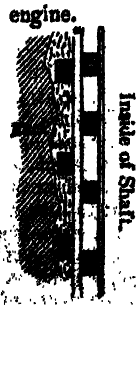
* The mode of obtaining the formula and construction is too long for insertion in this letter, but I will supply it if required.

CAST IRON TUBBING.

In the Mining Journal there are some useful communications on Engineering Works connected with Mining, from which we select the following on "Tubbing of Shafts;" the first description is the application of a cast-iron tub, for the stopping back of water at Mardyke Colliery, the property of the Irish Mining Company, by Mr. Dunn, of Newcastle-on-Tyne, the first attempt in Ireland. The colliery contains two principal seams of coal, lying at an angle of one in three. The upper one, lying at the depth of 22 fathoms, is exhausted; and in order to win the second seam, at the depth of 30 fathoms further, the waters of the upper seam were required to be either pumped up to the natural adit (12 fathoms from surface), or to be forced up to that



point of discharge by tubbing. In order to give this project a fair chance, a piece of fire-clay, lying below the first seam, was taken advantage of as a foundation, and the shaft was rounded out to ten feet diameter. The base of tubbing is made to rest upon a pair of oaken cribs, fitted closely to the fire-clay foundation, and wedged from behind as long as ever a wooden wedge can be driven. This done, the cast-iron tub begins to be built, consisting of cast iron segments, four feet long, two feet high, and three-quarters of an inch thick, with a rectangular flange all round, of three inches; between each of these segments are placed half-inch (end ways) fir deal, wherein to wedge; the space between the segments and the rock is also stuffed with small stones, and tightened with wood. The top of the segments was completed by a wooden crib, which was stayed fast against the superincumbent rock, and then the whole fabric underwent the most severe wedging so long as any leak continued; and, when finished, the shaft was laid perfectly dry, with the feeder of water discharging out at the adit 12 fathoms above, and the sinking of the shaft resumed perfectly dry. The pressure against every square inch of the lower range of tubbing is equal to two and a half atmospheres, or about 37 lb. per inch, and, taking the average altitude at 35 feet, the whole tub is sustaining a pressure of about 81,200 tons; and so complete is the job, that the sinking has been since carried on without any pumping apparatus, whilst sufficient water is discharging at the adit as would give employment to a heavy engine.



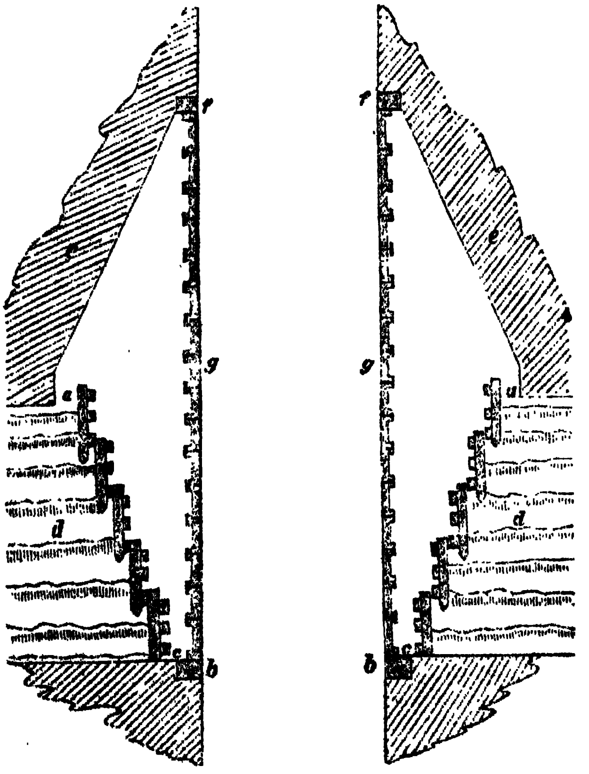
It is often found convenient to surmount these tubs with a sufficient quantity of stone walling, to enable the wedging to be made effective.

Some years ago Mr. Dunn effected the "winning" of a shaft, 30 fathoms deep, at Castle Comer, in the same county, by means of a plank tubbing, of 10 fathoms in length, constructed of three-inch planks, a, [illegible] against wooden cribs, b, and supported again[illegible] of inside cribs, c, which were, in their turn clead with common deals; this mode of stopping water was practised for many years previous to the invention of c[illegible] iron tubbing.

ACCOUNT OF SOME PLANS ADOPTED IN THE NORTH OF ENGLAND OF SINKING THROUGH QUICKSAND.

By Edward Stanley, Engineer, Sunderland.

When a "winning" numbers amongst its contingencies an encounter with a formidable quicksand, the preparations are, or ought to be, well digested as to power and appliances to overcome it. The viewer, engineer, and master sinker, each in their respective departments, take a retrospect of the means used on former occasions at other places, selecting the improvements that each adopted from previous works, which give every new "winning" an opportunity of profiting by the experience of the past. Boring by rods having determined the distance the sand is situated from the surface, and also the thickness of the sand previously; this operation is requisite, as the pit has to be chambered or bevelled like the frustrum of a cone, for the purpose of driving the spiling and laying cribs, each length and round in the descent being within the previous one. Supposing, for instance, the pit is 15 feet diameter, and the sand five fathoms, or 30 feet, in depth, and the spiling and cribs averaging each six inches thick, and the length of the spiles six feet, it remains now to examine what must be the diameter of the base of the frustrum of the cone, bevelled out so as to have the pit of sufficient size at the bottom of the sand as to admit the metal tubbing, and preserve the size of the pit. It will be, of course, premised that in six feet lengths it will require for the 30 feet, five lengths; if fewer lengths could be driven through the sand, the less the frustrum of the cone bevelled out in the rock; but long lengths, when driven, if the deviation is small, are like the trifling inaccuracy of an angle, which, if produced, are a long way out at the far end; it is, therefore, advisable to keep the lengths short, and in the annexed diagram are five. The five rounds of spiles and cribs, according to the former dimensions, will take up 10 feet of the diameter of the pit. We must add a clear space round at the surface of the sand, *a a*, of 18

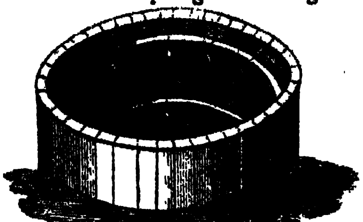


inches, which will add to the former diameter three feet, making it 13 feet. Further, we have to add the breadth of wedging crib, *b b*, cut at the bottom, and the space between its outer circumference and the lowest crib of the last spile, *c c*, together two feet each, which, added again to the 13 feet, makes 17 feet. This summary is the extra diameter over and above that of the pit, which we took at 15 feet, which

t as the diameter of the base of the frustrum of the cone.

it of this frustrum will depend upon the soundness of the limestone in contact with the sand. If not very sound, it must be carried further up, both for the safety of the sinkers and efficiency of the wedging crib at the top of the tub. The stratum of quicksand is shown by the letters *d d*, and the superincumbent limestone, *e e*, the top, or closing crib, *f f*, and the metal tubbing, *g g*; the manner of putting in which is by an intervening layer of deal sheathing, at the vertical and horizontal joinings, and subsequent wedging, has already been given in the *Mining Journal*. No letters of reference are put to the spiles and cribs, as they will easily be recognized, each spile having three cribs, at a distance apart of about two feet.

The following figure in perspective may give a more general idea of the mode of spiling and cribbing through the sand:—It will be perceived that the spiles are driven round the pit in the sand, and considerable attention and care is required on the first round—and the reason is, that when it is accomplished, and the three cribs inserted, the last of these acts as a guide for the circular insertion and driving of the succeeding set.



The cribs are kept up in their proper position by cleats or brackets (see fig.) till a sufficient external pressure keeps them tight. The spiles may be lighter near the surface of the sand if thought proper, and increase in thickness in the succeeding lengths with the pressure, but some consideration should at the same time be made for the large diameter requiring increased strength. It may, therefore, be consider d a prudent error to be too strong instead of too weak. A bird's eye view of the spiling, when complete, presents in principle an analogy to the elongation of a telescope.

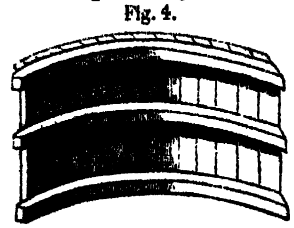
It may appear paradoxical to a person unacquainted with the district, to be told that the quicksand sometimes presents itself in the form of a hard rock, requiring the liberal use of gunpowder to detach it. This stone is very porous, through which immense quantities of water filter, and which, by a continuous, running, increase the size of the apertures, along which are at the same time conveyed a large quantity of sand to the pit. This result is technically called "guttering," and, on any cessation of pumping, and consequent rising of the water, it increases to a great extent. As the water is being drawn out of the pit, its receding from the gutters brings along with it sand, and hence their enlargement.

Fig. 3.

The annexed fig. shows a gutter fallen on to the limestone roof. At the bottom will be perceived a stream proceeding from the far end, having tributary ones from each side. These, in some cases, keep filling up the bottom of the pit with sand, nearly as fast as it can be sent to bank. With a sand of this kind, the general aim is, to keep the water always down if possible, for it has been found that its rising invariably increases this guttering, which proceeds in long irregular chasms radiating from the shaft.

As "spiling" cannot be driven under circumstances of this kind, the cribbing and lathing is put into the pit in sections, as shown in the annexed fig., varying in depth according to circumstances, and as the sand can be excavated.

Fig. 4.



These sections, when the round is complete, are kept together vertically by hanging deals, which are planks spiked to the previous rounds, or if it be the first round, to some suitable provision in the shaft; external pressure soon binds them horizontally. In some cases the sand becomes soft towards the bottom, and the sections are abandoned for spiling.

The foregoing details are enumerations of the resources hitherto applied, which appear, and, indeed, have been found in practice to answer best. In cases of difficulty, parties having works of this kind in hand are frequently favoured with friendly suggestions, the most popular of which appears to be the suspension of a cylindrical iron vessel, of proper diameter, which it is proposed to lower and lengthen at the top as the excavation proceeds. This suggestion has certainly feasibility about it, though it is said to have originated from an amateur.

The present article may not inaptly close with a brief notice of the Datton "winning," which is going on slowly but surely. The most determined and persevering spirit is shown by the owners (Messrs. T. R. G. Braddyll and Co.), and the viewer. The outlay of money is immense, and the conviction is, that the colliery will be eventually "won." The engine power is ample, cancelling accidents, which have not been frequent. The setting of the sand on the bucket on one occasion was so dense as to be the means of lifting a column of 33 fathoms, of 22-inch pumps, by the spears on the starting of the engine. The sand is hard, and the feeder flowing principally from the south, has occasioned great delay and expense by guttering. Fig. 4 is a representation of the wooden segments that are being put in to get through the sand previous to metal tubbing, which is now about half penetrated. The liberality and public spirit of the owners deserves the most complete success, which all parties earnestly wish may be the case.

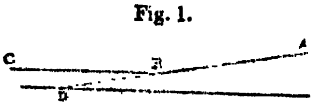
Another "winning" is now being made at Shotton, belonging to the Haswell Company, under the management of Mr. Thomas Foster, where the quicksand is very nearly arrived at. Should "any thing fresh" be brought into play at this place, either in getting through the sand, or the surface arrangements, it will appear in the Journal, with suitable illustrations, so far as it can be done without injury to the proprietors.

DREDGE'S SUSPENSION BRIDGES.

Sir—May I request the favour that the following remarks (on an anonymous communication, signed G. F. F., which appeared in your last Journal), may be inserted in your next.

The curve of a taper chain either connected or unconnected with the platform, is not a catenary, but one of very different properties; it might be easily demonstrated, but let that pass—for your correspondent makes as great a mistake in regard to the action of the oblique suspending rods in connection with the chains, and which is the only part of his letter I shall notice.

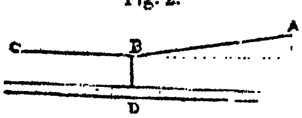
Fig. 1.



C, the centre of the bridge.

Let A B C represent a portion of the chain of a suspension bridge, B D an oblique suspending rod having the same inclination with the horizon as that portion of the chain B A; then will the strain upon B D, and of course upon B A, be proportional to the secant of the angle D A makes with the horizon, and there being no resolution of forces from the point B, there can be no tension in the direction B C.

Fig. 2.



C, centre of the bridge.

Again, put A B C part of the chain of a common suspension bridge, B A forming the same angle with the horizon as A D did in the former curve; then will the strain in the direction B A be proportional to the secant of the angle which it makes with the horizon (or the same as before), but by a resolution of forces, there would be a tension in the direction B C, α as the radius, which tension must be borne by a sufficient quantity of iron, and that iron causing a strain on the curve α as the secant of the angle B A makes with the horizon.

I shall take no further notice of this anonymous communication, but if your correspondent wishes further information, he must affix his name to his next letter, and then be careful what he says, for though the diagram he shows is totally different from the form proposed, his demonstration if carried out, would only tend to support that principle he is attempting to refute, and the several structures either in course of, or about to be erected in various parts of the kingdom, will at once silence every futile objection that can be raised against it.

I remain, Sir, your humble obedient servant,

J. Dredge.

Bath, August 16, 1841.

P.S. I would refer your readers who may be interested in this subject, to the drawings which have appeared in your Journal, and they will at once perceive that there is not the slightest similitude between them and that represented by your correspondent in the last number.

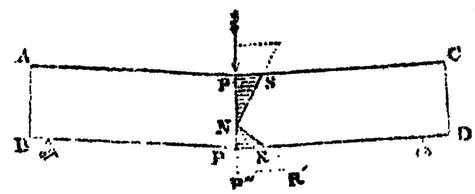
*** We know not what right Mr. Dredge has to make the insinuation which he has done in the above letter, with regard to an "anonymous communication." The article of G. F. F., was written without the slightest taint of presumption or slur upon Mr. Dredge's invention, it was a fair scientific enquiry into its merits, and such a one as every Inventor must be ready to encounter, if he be desirous of introducing to the scientific world any new form or invention. For the purposes of free and open discussion, we do not see the necessity of correspondents giving their names—and we shall leave it to G. F. F. to reply to Mr. Dredge's remarks.—Editor.

ON THE TRANVERSE STRAIN OF BEAMS.

By Herbert Spencer, C.E.

The following paper is an outline of a new system of investigating the laws of the transverse strain, differing from the usual method, in as much as it depends solely upon the position of the neutral axis. The results as here given, will probably not be considered sufficiently concise for practical application; but they are published in the hope that something useful may be elicited.

Fig. 1.

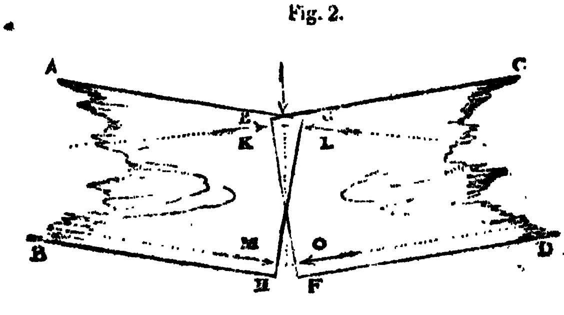


1. Let A B C D be a piece of timber, subject to the transverse strain in the direction shown by the arrow; and let P P′ be assumed as the plane of fracture, and N the position of the neutral axis. Take any line P′ R, to represent the resistance to fracture of all the fibres in the bottom lamina, then by the theory of the lever, if N, R, be joined, and any line be drawn parallel to P′ R, and terminated by N P′, and N R, it will represent the relative effect of all the fibres in its latitude, and therefore the whole triangle N P′ R, will denote the resistance to fracture of all the fibres in tension. In the same manner, a triangle N P S may be assumed, which shall represent the resistance of all the fibres in compression.*

2. Now the mode of action of the fibres in resisting the force impressed, involves the necessity of the equilibrium of the compressive and tensive resistances, about the transverse line through N, that is the neutral axis; for suppose a saw-gate made down the line P N as far as N, and the force to be then applied; a deflection will immediately take place, and the surfaces of the opening will come into close contact. Carrying out the idea it would appear, that the deflection would continue, until the resistance to compression in the upper portion P N of the plane of fracture, is equal to the resistance to tension in the lower portion; or that in the uncut beam, the neutral axis arranges itself so that these forces are in equilibrium.

As it is this theory upon which all that follows depends, and which if disproved, will invalidate the succeeding calculations, it may be well to give a further illustration.

Fig. 2.



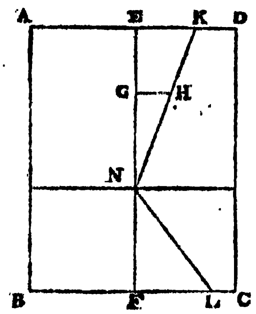
Let A B C D be a piece of wood as before, subject to transverse strain, and let E F and G H be the planes of fracture; (the diagram being necessarily greatly exaggerated to make the action clear) draw the arrows K, and O, perpendicular to E F, and L, and M, perpendicular to G H; then K, and L, will represent the direction of the resistances of certain fibres to compression, and M, and O, those of the resistances of other fibres to tension; (the forces extending the fibres are acting from H towards B, and from F towards C, and the resistances will obviously be in the reverse directions)—now K, and O, being perpendi-

* This theorem affords a simple demonstration, that the strength varies as the square of the depth; for if the depth be increased, (the neutral axis remaining constant) so that N P′ becomes N P″, the original supposition being carried out, the triangle N P″ R′ will denote the new tensive resistance; but the triangle N P″ R′, is to the triangle N P′ R, as $(NP'')^2$ to $(NP')^2$; that is the resistance of the fibres in tension, varies as the depth square, and the same will be true of those in compression.

cular to E F are parallel, and the same may be said of L, and M; hence if produced they will form a parallelogram, and the resultant diagonal of K, and L, will be equal, and in the opposite direction to that of M, and O; that is, the forces will be in equilibrium; but if K, and L, be greater than M, and O, their resultant diagonal will also be greater, and motion must ensue, that is such a state of things cannot exist. And what is true of these single forces, will be true of the forces of all the fibres collectively; or the resistances to compression and tension will be equal. It may be said that this explanation, involves the necessity of the centre of motion N, being midway between the contending forces, and that that does not obtain, in the case in point; but this does not prevent its application, for the resistances to tension though exercised nearer to the neutral axis, are greater in amount, so that the effect is practically the same.

3. The position of the neutral axis therefore, depends upon the ratio between the tensive and compressive resistances of the material, and by the application of the above principle, with the necessary data, its situation may be found. The next step will be to develop the general expression for obtaining it in simple cases.

Fig. 3.



Let A B C D be a transverse section of a rectangular beam; assume N as the middle of the neutral axis, and through it draw the central line E F, and in F C take any line F L, to represent the resistance of all the fibres in the line B C; join N L, and the triangle N L F will denote the resistance of all the fibres in tension. Make N G, equal to N F, and draw G H perpendicular to it, and let G H, be to F L, as the resistance to compression, is to the resistance to tension in the material in question; join N H, and produce it to K, then the triangle N E K will represent the resistance of all the fibres in compression, and will consequently be equal to the triangle N F L. Let x equal N F, the distance of the neutral axis from the bottom; take d for the depth, and let p and q stand for F L and G H respectively; that is, let them denote the tensive and compressive resistances.

Now by similar triangles N G : G H :: N E : E K,

or $x : q :: d-x :$ E K, or E K $= \frac{q(d-x)}{x}$,

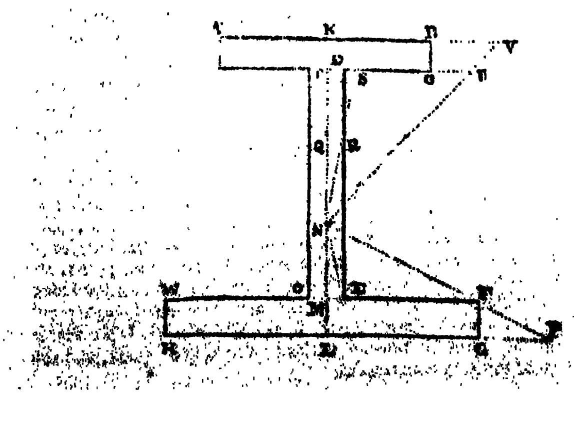
$\therefore \frac{(d-x) \times \frac{q(d-x)}{x}}{2} =$ area of triangle N E K; and $\frac{p\,x}{2} =$ area of triangle N F L; hence we have the equation,

$\frac{p\,x}{2} = \frac{q(d-x)^2}{2x}$ or $p\,x = \frac{q(d-x)^2}{x}$, hence $p\,x^2 = q(d-x)^2$ or $\frac{p}{q}x^2 = d^2 - 2dx + x^2$. dividing by x^2, $\frac{p}{q} = \frac{d^2}{x^2} - 2\frac{d}{x} + 1$ and extracting root

$$\frac{d}{x} - 1 = \sqrt{\frac{p}{q}} \text{ or } \frac{d}{x} = \sqrt{\frac{p}{q}} + 1, \text{ and } x = \frac{d}{\sqrt{\frac{p}{q}} + 1} \qquad (1.)$$

4. The application of the principle to the common form of girder, is the next case that suggests itself.

Fig. 4.



Let A B C D E F G H be the section, assume N to be the middle of the neutral axis, and through it draw the central line K L, and in the line E O, take a line M E, to represent the resistance to fracture of all the fibres between E, and O, and for the sake of conveniences, let M E be equal to half E O; join N E, N F, and let N F, and H G, produced, meet in P.

Make N Q, equal to N M, and draw Q R perpendicular to it, and let Q R, be to M E, as the compressive resistance in cast iron, is to the tensive resistance; join N R, and produce it to S, and as T S : T D, so make T U : T C; join N U, and let N U, and A B, produced, meet in V.

Then in accordance with the principles as applied in the last case, the figure N L P F E, will represent the resistance to fracture, of all the fibres below the neutral axis; and the figure N S U V K, the resistance of all those above, and these will be equal.

Now let $x =$ N L the distance of the n. a. from the bottom.

$d =$ the whole depth.
$d' =$ depth of top flange.
$d'' =$ depth of bottom flange.
$b =$ breadth of top flange.
$b' =$ ditto of middle rib.
$b'' =$ ditto of bottom flange.

And as before, let p and q represent M E and Q R respectively.

Then N M : M F :: N L : L P or $x - d'' :: \frac{p\,b''}{b'}$* $:: x :$ L P

or L P $= \frac{x \times \frac{p\,b''}{b'}}{x - d''} = \frac{p\,b''\,x}{b'(x-d'')}$. Therefore the area of the figure N L P F E will be represented by,

$$\frac{p(x-d'')}{2} + d''\left(\frac{\frac{p\,b''}{b'} + \frac{p\,b''\,x}{b'(x-d'')}}{2}\right) =$$

$$\frac{p(x-d'')}{2} + \frac{p\,d''\,b''}{2\,b'} \times \left(1 + \frac{x}{(x-d'')}\right)$$

Again, as N Q : Q R :: N T . T S,
that is $x - d'' : q :: d - d' - x :$ T S,

or T S $= \frac{q(d-d'-x)}{x-d''}$.

But T D : T S :: T C : T U or $p : \frac{q(d-d'-x)}{x-d''} :: \frac{b\,p}{b'}$† : T U

that is T U $= \frac{\frac{b\,p\,q(d-d'-x)}{b'(x-d'')}}{p} = \frac{b\,q(d-d'-x)}{b'(x-d'')}$.

And N T : T U :: N K : K V or

$d - d' - x : \frac{b\,q(d-d'-x)}{b'(x-d'')} :: d - x :$ K V,

hence K V $= \frac{\frac{b\,q(d-d'-x).(d-x)}{b'(x-d'')}}{d-d'-x} = \frac{b\,q(d-x)}{b'(x-d'')}$.

And the area of the figure N S U V K, will therefore be represented by

$$\frac{d-d'-x}{2} \times \frac{q(d-d'-x)}{x-d''} + d'\left(\frac{\frac{b\,q(d-d'-x)}{b'(x-d'')} + \frac{b\,q(d-x)}{b'(x-d'')}}{2}\right)$$

---

* As $\frac{b'}{2}$ represents the resistance of all fibres between O and E; $\frac{b''}{2}$, will denote that of all those between W and F; and $(\frac{b''}{2} \div \frac{b'}{2})$ that is $\frac{b''}{b'}$, will express the multiple, that the number of fibres between W and F. is of the number between O and E, and if p equal the resistance of fibres between O and E, then $p \times \frac{b''}{b'}$ will equal that of all fibres between W and F. It is necessary that the quantity should be put in this form, instead of the simple fraction $\frac{b''}{2}$, in order that the value of L P, should involve the term (p).

† The last note explains this also.

But, area N L P F E = area N S U V K.

Hence we have the equation,

$$\frac{p\,(x-d'')}{2}+\frac{p\,d''\,b''}{2\,b'}\times\left(1+\frac{x}{(x-d'')}\right)=\frac{q\,(d-d'-x)^2}{2\,(x-d'')}+$$

$$\frac{q\,d'\,b\,(2\,d-2\,x-d')}{2\,b'\,(x-d'')}.$$ And multiplying by $2\,(x-d'')$,

$$p\,(x-d'')^2+\frac{p\,d''\,b''}{b'}\times(x-d''+x)=q\,(d-d'-x)^2+$$

$$\frac{q\,d'\,b\,(2\,d-2\,x-d')}{b'},\quad\text{or}\quad p\,b'\,(x-d'')^2+p\,d''b''\;(2\,x-d'')=$$

$$q\,b'\,(d-d'-x)^2+q\,d'\,b\,(2\,d-2\,x-d').$$

Expanding the squares we have

$$p\,b'\,(x^2-2\,d''\,x+d''^2)+p\,b''\,d''\,(2\,x-d'')=q\,b'\,(d^2+d'^2+x^2+$$
$$2\,d'\,x-2\,d\,d'-2\,d\,x)+q\,d'\,b\,(2\,d-2\,x-d'),\qquad\text{or}$$

$$p\,b'\,x^2-2\,p\,b'\,d''\,x+p\,b'\,d''^2+2\,p\,b''\,d''\,x-p\,b''\,d''^2=$$
$$q\,b'\,(d^2+d'^2-2\,d\,d')+q\,b'\,x^2+2\,q\,b'\,d'\,x-2\,q\,b'\,d\,x+$$
$$q\,d'\,b\,(2\,d-d')-2\,q\,d'\,b\,x.$$

And by transposition,

$$(p\,b'-q\,b')\,x^2+(2\,p\,b''\,d''-2\,p\,b'\,d''+2\,q\,b'\,d-2\,q\,b'\,d'+$$
$$2\,q\,d'\,b)\,x=p\,b''\,d''^2-p\,b'\,d''^2+q\,b'\,(d^2+d'^2-2\,d\,d')+$$
$$q\,d'\,b\,(2\,d-d'),$$

$$\text{hence } x^2+\frac{2\,(p\,d''\,(b''-b')+q\,b'\,(d-d')+q\,d'\,b)}{p\,b'-q\,b'}\,x=$$

$$\frac{p\,d''^2\,(b''-b')+q\,[b'\,(d-d')^2+d'\,b\,(2\,d-d')]}{p\,b'-q\,b'}$$

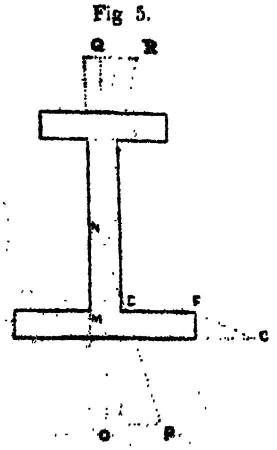
And completing the square, extracting the root, &c., we have

$$x=\sqrt{\left\{\frac{p\,d''^2\,(b''-b')+q\,[b'\,(d-d')^2+d'b\,(2\,d-d')]}{p\,b'-q\,b'}+\left(\frac{p\,d''\,(b''-b')+q\,b'\,(d-d')+q\,d'\,b}{p\,b'-q\,b'}\right)^2\right\}}-$$

$$\frac{p\,d''\,(b''-b')+q\,b'\,(d-d')+q\,d'\,b}{p\,b'-q\,b'}\qquad(2.)$$

And thus we obtain the situation of the neutral axis. It must be admitted that the equation is rather forbidding in appearance, but the reduction of the value of x, will not be found so tedious as may at first be imagined, since the quantities are simple, and the same combinations often repeated.

Fig 5.



5. Assuming that N L, the distance from the centre of the neutral axis, to the bottom of the girder, has been found by equation 2; we shall at once be able to determine the dimensions of a rectangular beam, whose strength shall be equal to that of the girder.

The figure being constructed as before, produce N L to O, and N E to P, and let O P be drawn at right angles to N O, the distance L O being supposed to be such, that the area of the figure M E P O, may be equal to that of the figure M L G F, and consequently, that the triangle N O P, and the figure N L G F E, may have equal areas.

Since therefore the area N L G F E, which represents the resistance to fracture of that portion of the girder below the neutral axis, is equal to the triangle N O P, which will indicate the resistance of the middle rib, produced to an imaginary point O: by finding the distance L O, we shall obtain the dimensions of a simple rectangular rib, having a strength equivalent to that of the portion of the girder below the neutral axis N.

Let the known distance N L, be represented by (a), and L O by (x), and the other dimensions remain as before.

Then $a-d''\,:\,\frac{b''}{2}\,::\,a\,:\,\text{L G or L G}=\frac{a\,b''}{2\,(a-d'')}$,

and $d''\,\dfrac{\left(\frac{b''}{2}+\frac{a\,b''}{2\,(a-d'')}\right)}{2}=$ area of figure M L G F.

Again, $a-d''\,:\,\frac{b'}{2}\,::\,a+x\,:\,\text{O P or O P}=\frac{b'\,(a+x)}{2\,(a-d'')}$.

And $(x+d'')\times\dfrac{\left(\frac{b'}{2}+\frac{b'\,(a+x)}{2\,(a-d'')}\right)}{2}=$ area of figure M E P O,

hence, by the construction we have the equation,

$$d''\left(\frac{b''}{4}+\frac{a\,b''}{4\,(a-d'')}\right)=(x+d'')\times\left(\frac{b'}{4}+\frac{b'\,(a+x)}{4\,(a-d'')}\right)$$

$$\text{or }\frac{d''\,b''}{4}\left(1+\frac{a}{a-d''}\right)=\frac{b'\,(x+d'')}{4}\left(1+\frac{a+x}{a-d''}\right)$$

Multiplying by $4\,(a-d'')$ we have,

$$d''\,b''\,(a-d''+a)=b'\,(x+d'')\times(a-d''+a+x)$$
$$\text{or,}\quad d''\,b''\,(2\,a-d'')=b'\,(x+d'')\times(2\,a+x-d''),$$
$$\text{and,}\quad d''\,b''\,(2\,a-d'')=b'\,(x^2+2\,a\,x+2\,a\,d''-d''^2)$$
$$\text{hence,}\quad\frac{d''\,b''\,(2\,a-d'')}{b'}=x^2+2\,a\,x+2\,a\,d''-d''^2$$

$$\text{by transposition, }\frac{d''\,b''\,(2\,a-d'')}{b'}+d''^2-2\,a\,d''=x^2+2\,a\,x,$$

$$\text{completing the square, }\frac{d''\,b''\,(2\,a-d'')}{b'}+d''^2-2\,a\,d''+a^2=x^2+2\,a\,x+a^2$$

$$\text{extracting the root, }x+a=\sqrt{\frac{d''\,b''\,(2\,a-d'')}{b'}+(d''-a)^2},$$

$$\text{or,}\quad\text{N O}=\sqrt{\frac{d''\,b''\,(2\,a-d'')}{b'}+(d''-a)^2}\qquad(3.)$$

The points Q and R, having been assumed in the same manner as O and P, we shall have the proportion, O P : Q R : : p : q, and as the triangles N Q R, N O P, are equal,

O N : N Q inversely as p to q,

that is, $\text{N Q}=\dfrac{p\times\text{O N}}{q}$,

and the whole depth, $\text{O Q}=\text{N O}+\dfrac{p\times\text{N O}}{q}$ (4.)

It will be seen therefore, that by applying the equation No. 2, to ascertain the position of the neutral axis, and subsequently Nos. 3 and 4, we obtain the depth of an imaginary rectangular beam, having the same thickness as the middle rib, whose strength shall be equal to that of the girder, thus bringing us within the reach of the usual formula.

It may be as well to repeat the remark made at the commencement, that this system is not proposed for practical application in common cases; the essay being merely intended, as an exposition of another mode of viewing the action of the transverse strain, and as affording a means, should the principles be found correct, of testing the accuracy of the common approximate methods.

Derby, August 11, 1841.

Pacific Steam Navigation.—Extract of a letter received by the Directors of the Company from Mr. Wheelwright, dated Lima, April 28, 1841.—"Captain Peacock arrived here on Saturday, the 24th, having consumed nothing but Chili coal during the voyage:—his calculations have been most beautifully carried out, for he has not been 15 moments out of his time, on arriving at and sailing from each port in the voyage, from Talcahuano to this place, a distance of nearly 1,760 miles; and it affords me pleasure to remark, that his zeal in the cause of the Company merits the highest praise. His ship is, I am happy to state, well regulated with a due regard to economy, and the several departments are most judiciously arranged."

CANDIDUS'S NOTE-BOOK.

FASCICULUS XXX.

> "I must have liberty
> Withal, as large a charter as the winds,
> To blow on whom I please."

I. It is a most fortunate circumstance that the Croakers, and Screech-owl school of philosophers, both contradict each other, and are contradicted by experience; else we should have a most woful time of it, were we to pay attention to all their notable advice in regard to the *hygeine* regimen of architecture. At one time the public—at least the *nervous* public—are scared by being told that St. James' Park is the seat of malaria, and by being made to believe that Queen Victoria actually dwells in the midst of pestilence, although she does so only metaphorically, like all sovereigns, amid the moral malaria of a court. Next come the ventilation folks, who would fain persuade us that we are now all suffocating ourselves in rooms whose atmosphere is incapable of supporting animal life, owing to our present defective modes of construction. And indeed were the atmosphere in our houses as oppressive and suffocating as their doctrines, it would be so deadly, that I question if any sort of ventilation could correct it—except it were the ventilation occasioned by a hearty laugh. It was certainly a very great piece of presumption on the part of the Old-Londoners to presume to exist, as they did, cooped up in narrow lanes and alleys, where the different stories of the houses, projected over each other, so that the occupiers of the garrets could *Pyramus-and-Thisbe* with their opposite neighbours. No less impertinent is it that even nowadays, people will presume to fancy they can contrive to exist huddled together in the cabin of a steamer, in an atmosphere reeking with frowsiness!—and sleeping in boxes, not very much bigger than—and certainly not so well aired as, an ordinary dog-kennel. Did I wish to set up a fussy doctrine of my own, I should say that sea-sickness is chiefly occasioned by the horrible agglomeration of impurity condensed between the decks of a ship. Nevertheless instead of keeping quietly at home in their own comfortable rooms, many people are seized every season with a desperate fit of fidgetiness, until they can regale themselves with fresh air in a steamer, and squeeze themselves into poking little rooms in crowded lodging-houses, peopled from Cockney-Land, in a place that looks just like a suburb of it.—Well if the Ventilation folks can frighten them a bit, they may so far do good. If too, their doctrine be worth anything, an act ought to be passed making it a cognizable offence, for any one to get a genteel *squeeze*, especially if their "saloons," as the newspapers call them, consist of no more than two ordinary-sized upstair parlours, with a little cabin beyond them, made to perform the part of Boudoir—for that 'night only'. As for that, it matters very little how many or how spacious the rooms themselves may be, if more persons are to be crammed and jammed into them than their area can well contain; for it is no less absurd to attempt to pour a gallon into a quart mug, than a quart into a pint one. "Was not the squeeze, last night at ——'s actually insupportable?" was a question once asked, and produced the following reply: "It was, indeed, tremendous, but not insupportable, since the gentlemen supported the ladies, and the ladies supported the gentlemen."

II. Though the first has been a long one, I must give a second act to the farce of Ventilation. If the Terrifiers be in the right, ought not all under-ground kitchens, servants' halls and other rooms, to be strictly prohibited?—or does it not matter whether the High-Life-below-stairs part of the creation are suffocated or not? We are told that those whose avocations compel them to be chiefly in the open air, are proportionable healthier than others; and in proof of this we are perhaps referred to the striking difference between a ploughman, and a weaver;—a gamekeeper ranging about the woods, and a tailor doomed to sit all day upon the piece of wood called his shop-board. In all such arguments the stress is laid exclusively upon the single circumstance that happens to make for it. Here, the difference is attributed entirely to air,—to exercise, diet, &c., nothing. Should a tailor chance to drink himself into his grave, the "Ventilators" would seize upon him—not exactly after the fashion of body-snatchers,—but as an instance of the deplorable consequences of the want of fresh air. Well but put exercise to fresh air, and good appetite and its wherewithal, to them both, and they achieve wonders.—Yet, your jolly, jovial, foxhunter dies at the venerable age of forty, while some poor feeble, sickly, bookworm who immures himself almost constantly within his study, outlives another foxhunting generation, keeping among the living for fourscore years.—It is unnecessary to repeat so well known an anecdote as that of Fontenelle's "slow poison;"—which, by the by, is only one of the slow poisons which certain ingenious gentlemen have from time to time invented for the laudable purpose of alarming their neighbours. I remember once reading an awful medical invective against carpets,—the general use of which was said to have rendered people less healthy and long-lived than their ancestors who were unacquainted with such foolish luxuries. Yet I make no question but that the Doctor himself had his rooms carpetted, as well as his neighbours.

III. The author of the World of London, in Blackwood's Magazine, speaking of the building at the corner of Downing-street, observes that it is by "Sir John Soane, of Bœotian celebrity, who, together with Nash, has done so much to deprave our metropolitan taste in architecture, that another invasion of the Goths and Vandals were more to be desired than deplored." Indeed it is truly wonderful, and not a little scandalous also that two such Bœotians as Soane and Nash should have obtained fat-headed patronage to the extent they did, and been permitted to play their tasteless and extravagant pranks, while John Bull paid the piper. Both of them were addicted to the expensive practice of experimentalizing with their buildings, constructing, pulling down again, and reconstructing afresh, as if alterations of that kind cost no more time or money than they would have done in a drawing. Such was notoriously the case with Buckingham Palace, such too was it with the Downing Street edifice, which after all is unfinished, and doomed never to be finished, it having been commenced so Bœotianly and bunglingly that it cannot possibly be continued Northwards without either being twisted, or else projected into the street, so as to extend across the foot-pavement. Therefore it is likely to remain as long as it lasts, in statu quo,—a monument of its architect's taste, and his great affection for the "scored pork" style, and likewise of his extraordinary ingenuity, the entablature being most artfully contrived to block up a series of mezzannie windows just behind, and separated from it merely by an interval of three or four inches. It is lucky for Soane that this fault has escaped the notice of his friend Gammon, who has just found out what he might have discovered many years ago that Soanean Gothic is very *so-soish* stuff. But poor little Gammon's esteem for Soane, has steamed itself quite away, and is now utterly evaporated.

IV. One of the least exceptionable samples of Soane's taste is the basement of the State Paper Office, St. James' Park, where he has introduced a rather novel mode of rustication, which is at once rich and sober in effect. There are also one or two other good points about that building, although as a whole it is not particularly happy. It appears to be no more than a private house, and even as such by no means a large one. Most certainly there is nothing whatever in the exterior to indicate, or even remotely suggest for what particular purpose the building was erected. In regard to Soane's works generally, it is somewhat remarkable that they have been so very little noticed by foreigners, either for approbation or the contrary. The venerable architect's affection or appetite for his "scored pork" was so inordinate, that he did not scruple at times to employ that singular species of decoration even internally.

HINTS ON ARCHITECTURAL CRITICISM.—Part I.

It is a very delicate thing to insist on primary principles, when the very suggestion that a knowledge of those principles is necessary, seems almost like a whisper of insult. Thus, to intrude with an alphabet for the critic, in an age when men have grown grey in criticism, becomes scarcely pardonable;—nay it would be almost dangerous, but for the suggestive attitude the writer would assume, in pleading anew those elemental truths, by which alone the critic can arrive at an equitable conclusion. If therefore, out of regard perhaps for one or two, (who have viewed the vision of Palladio's family with horror, as if the harmless race of a Banquo had been passing in review,) I draw for a little a vail upon the past to introduce a new subject, and appear on a new scene, the spectator must judge me mildly; for I am no literary coxcomb, puffing myself into notice, but anxious,—deeply anxious, to remove some of those weeds, which entangle around to choke the beautiful flowers of a still more beautiful art.

The subject of consideration, is criticism, which, like politics, betrays many currents of opinion, and many hostile enthusiasts.

It is right that there be enthusiasm, for without it art would slumber, but it is also right that every persuasive argument be adduced, to free the mind from certain prejudices, which lead the enthusiast astray; and it is a commendable task, to try at turning these various currents of opinion into one deep channel, the original source of which shall be "truth."—This preface must suffice. I am satisfied after this attempt at beckoning the attention towards what I would present, to leave it to the reader to judge, whether I quibble merely for indefinite purposes, or strive with the noble and the proud aim of ameliorating my country's art.

First, what is criticism?—Criticism is a branch of polite science, and when found in union with art becomes an index to its position. From this arises its importance. It is also a court, where the several disputes of art are brought to issue, and upon the decisions of which the public opinion stands: hence arises its influence. The foundation of its laws, is based on sense, imagination, and judgment, as the three natural powers it attempts to move. Its laws of adjudication vary according to the claims of art, and according to the nature of appeal; and from the labour necessary to frame these laws, and to apply them, is inferred the necessity of their adoption. An appeal to the judgment of criticism, is based upon plausibility, and implies public assent to certain principles; these however, critics as counsel in the social contentions of art, quarrel upon, whilst the judge "nature" sits to disentangle and apply them. The arguments vary first, according to the art, and secondly, accordingly to the nature of its claim,—its claims being always in the shape of some emotion, (emotion being the aim of the affecting arts) the fitness, or unfitness of which, for the present is immaterial. The institution of the court itself, is founded upon presumed error, as implying an uncertain acquaintance with those laws, which are the philosophy of our taste. It follows then, in order to meet the wisdom of such an institution, that the principles which detect the propriety, or expose the error of appeal, should be free from arbitrary application. It is first then, upon the necessity of a judgment in matters of art, secondly,—upon the required clearness of the laws of judgment, and, thirdly, upon the arbitrary interpretation of those laws, which interpretation, I for the present assume to exist, that I am induced to throw out a few hints on criticism, which I hope will be received by the reader with a politeness due to the subject, however in exhibiting this politeness, he may disguise a dislike to what may appear officious interference in the writer. However these hints may be generally received, the man of correct taste knows that it is not an irrational task, to dissect those principles which aid us, or ought to aid us, as we either feel or affect a love for the great examples of art. He knows that about architectural excellence there is an air of mystery: so that without any implied reproach upon the elegance of any choice hitherto made, or which may be made, he would prefer our being guided by principle, rather than by instinct, in our search after the beautiful, and that instead of wrangling over fragments, like beasts over carcases, he would choose an explanation of the real basis of choice, of which a noble profession cannot be ashamed. The very circumstance of our choice being a habit, requires that some effort be made to enlarge and unfetter the mind, so that by infusing into it those ideas which are the very key to effective design, we may stand in rivalry with the ancients;—adopting if we please their beauties, but adopting them from choice, not from necessity.

I feel strongly on the subject, because it is so important that architecture should rank amidst the poetic arts, and that the attainment to architectural excellence, shall be only by the acknowledged effort of genius. I feel strongly too, because I conceive it is owing to our negative character as artists, and our supine imitation, that critics rise no higher in their views. The architect of original bent, feels the incompetency of ordinary men to discuss his claims: a critic in his idea, being a man who has only read through Creasy or Stewart, or if learned in Christian architecture, has his dictionary of reference only in some convenient examples. He is unfamiliar with the man of that severe yet elegant mind whose opinion he covets. He has been deceived in fancying architecture an art, where conception, the inseparable companion of genius, might alight. The root of the defect at once appears in criticism, which is confined to certain laws inimical to invention. The evil of this criticism is, that it limits that range of mind which every other poetic art allows, and is either founded on a presumption against the poetry of the art, or against the ability of its students. If in the former ground it is inconsistent, because that combination of parts, with the ancients so fortuitous, being deemed by many the monopolist of beauty, shows an argument then against the poetry of the art, for poetry is confined to no set disposition of forms. If on the latter ground it is a libel upon the genius of our nation, and stagnates by its mean policy, those efforts which might introduce fresh beauties amongst us. I admit that our rules are protective, and exclude many incongruities; but would it not be more honourable to make the antique amenable only to fresh creations? very possible if as artists we catch the spirit of our masters. It being evident then, that our art for inventive beauty is far behind the other arts, with which it claims sisterhood, and that however good this claim to equality may be, it does not appear either from the pen of the critic, or the example of the architect, to be so dignified; it follows, as a natural consequence, that to maintain this kindred claim, there should be shown a similarity of laws, by which the composition is governed, and by which the emotions are engaged: it follows too, if this be the case, that then, our laws of criticism are erroneous, or capricious, being essentially at variance with those of other arts.

In watching the progress of a design, in either art, to its completion, that is in observing that anatomy of thought out of which the composition is formed, we may perceive a relationship existing, although we do not yet admit its existence. We read an able critique upon poetry, music, sculpture or painting, and the mind responding with ready fidelity to truth, becomes at once conscious that it hears in that criticism, but the echo of its own suggestions: but architectural criticism we do not feel in this way, and purely because its compositions are not criticized on the same ground, the mechanical being ever judged as in partial skirmish with the poetical. Architecture however, is not more mechanical than the other arts, for the conception which occupies the brain of the poet, or the painter, can only acquire a correct and tangible shape by a process of adjustment. Calculation enters into the design; associations are dwelt upon; and the sentiment which is to appear is only featured by a careful arrangement. Music, amidst all its sweetness and harmony, has its mechanism. The rush of chords, the softer modulation, independent of the art, which, if I may so speak, can embody for the ear its anticipations, is but the sale of a passion, or a sentiment, shaped and tutored in the mind, with reference to situation, circumstance, time and probability. Each art is alike too in its finished performances: they are so many appeals to the mind through the senses; music, through the ear, sculpture, painting, and architecture through the eye, poetry through the eye and ear, and it is upon this beautiful and exquisite web of sensation, that the power of art moves. But supposing that architecture be equally with the other arts, a mirror where the eye can seek objects, which the mind may enjoy, a barrier intrudes itself at once, in the shape of that word, "taste," (which like the ghost of Junius assumes a variety of shapes) to make it doubtful after all, whether there can be shown common grounds, upon which the feelings are moved. It will be necessary then, to define this word "taste," because if this be unexplained, we may be only right by chance.

It has been deemed a fruitless task, to reconcile to a principle the varying opinions current upon the same object in arts, each of which is termed the opinion of taste, because of the different degrees of sensibility and imagination found in different minds, and because it has been observed, that the same object, which is viewed carelessly by one man, fills another man with exquisite delight. Strange as these differences may appear, they are all to be traced to one source. The taste of a man which is a progressing principle, receives its perfect development only from time. Taste which in infancy is mere sense, becomes improved as imagination and reason blend to assist it.—Taste resulting not from a simple idea, but from the union of reason and imagination, varies then not according to that chance inseparable from a simple notion, but according to the effort of the imagination and the exercise of the judgment, the latter quality of the mind being a determinable thing, whose degree of ability is proportioned to the attention and care bestowed. Imagination too, though a power extremely elastic, resembles when engaged with architecture, either more or less that faculty we denominate "taste," for its essential power then lies in tracing resemblances, and it is either perfect or advancing towards perfection, according to the degree of judgment in simultaneous exercise. Thus taste is subject to degree, and according to this degree of taste in different individuals, we find the degree of refined pleasure which a work of art produces. Taste which is a habit is therefore imperfect taste, because inimical to progression. Hence habit which is the origin of our views in a great measure, may explain the source of our architectural taste.

Independently of this definition of taste, and the grounds of its support, there is a further difficulty attendant upon its application to architecture, from the circumstance of there being little or no direct appeal to the sympathies, which the painter, the poet, and the sculptor, so powerfully affect, and which the rudest mind intuitively feels, without previous study, to acquaint him with the source of his emotion. This is one reason why public opinion varies so much; men untaught, with their judgments unassisted, feeling that emotion is the object of the art, are precipitated into hasty conclusions, just because their sympathies cannot be awakened. A correct taste in architecture is more difficult than in any other art, because the ideal resemblances affecting the mind are more remote: and this is the reason why the taste is pleased by figures, pictures, statues or striking ornaments, to the prejudice very often of a taste strictly architectural;—the mind being conducted towards familiar objects.

The essential difference between architecture and the other poetic arts, consists then in this suggestive character, whilst the poetry it exhibits, appears in expression, attitude, or relative position. It has however, all the attributes of the other arts at command, and which it makes subsidiary; and thus its claims to criticism are as strong and as important, as the noble art of the painter, or the sculptor. Having then endeavoured to state that architecture is equal to the other arts, in its claims to liberal criticism, I shall reserve it for my next to show the origin of its effects upon the mind, by a definition of that faculty, inherent in us, by which we extract emotion from attitude, proportion and position, even when these three essentials have no counterpart in nature.

FREDERICK EAST.

August, 1841.

ENGINEERING WORKS OF THE ANCIENTS, No. 8.

DIONYSIUS of Halicarnassus who lived in the time of Augustus, is the next author who contributes to our series, having extracted from his Roman Antiquities the following accounts of Roman works.

BRIDGE OVER THE TIBER.

Ancus Marcius, the 4th King of Rome (B. 3, ch. 14,) is said to have been the first who built over the Tiber the famous wooden bridge, which is considered as sacred. It must only be made of wood, and neither iron nor copper may be used in it. When any damage occurs it is the duty of the pontiffs to see to the repair, and to perform certain sacrifices prescribed by law during the progress of the works.

Ancus Marcius greatly enlarged the city of Rome, and built the port of Ostia at the mouth of the Tiber.

SEWERS.

TARQUINIUS PRISCUS, the 5th King (B. 3, ch. 20), built the walls of Rome of large squared stones, and commenced the sewers, by which the waters are collected in the streets of the city, and carried into the Tiber. The work is admirable, and beyond anything that can be said. For my own part, I believe that Rome has nothing more magnificent, nothing which better shows the grandeur of her empire, than her aqueducts, streets, paved roads, and sewers; I judge thus not only on account of their utility, but still more on account of the immense outlay which they have required. To prove what I assert, I will only instance the sewers. According to Caius Aquilius, having been for some time so neglected that they were stopped up, the censors concluded a bargain with a contractor to clean and repair them for a thousand talents.

We cannot pass over this tribute of the old historian without remarking that while the temples of Greece are scattered in ruins, and their proudest ornaments become the trophies of barbarians, the roads, aqueducts, and sewers of the Romans still minister to the wants of nations, centuries after the power of their founders has ceased to exist. The English emulate the Romans in the useful nature of their enterprises, and we trust that the labours of our engineers may minister as long to the service of the world as those of their predecessors.

GREAT CIRCUS.

Tarquin also embellished the Great Circus between the Aventine and Palatine mounts, and was the first who constructed around this circus covered seats, whereas the practice formerly was to place scaffolding around.

TARQUINIUS SUPERBUS.

Tarquin the Proud (B. 4, ch. 10,) the seventh and last king of Rome, employed the people on the public works in order to occupy them and prevent them from plotting. He continued to the Tiber the sewers begun by his grandfather, and carried out several of his unfinished works.

STRABO.

Having thus dismissed Dionysius of Halicarnassus, we come to Strabo, one of the most celebrated of the geographical writers of the ancients, and from whom, as from Diodorus Siculus, much information is to be gleaned as to ancient mining, a most important branch of engineering, as bearing upon earthworks. We shall first take the third book.

MINES IN SPAIN.

A chain of mountains, (the Sierra Morena), parallel to the Betis (Guadalquivir) extends towards the north, approaching more or less the banks of the river; it contains a great many mines. Silver is found every where in the neighbourhood of Ilipo and Old and New Sisapone (Almaden). Near the place called Cotinas, gold and copper are worked together. The mountains on the banks of the Anas (Gaudiana) also contain mines.*

* B. 3, ch. 2.

From Turdetania is exported cinnabar equal to that of Sinope. There is also found fossil salt.*

What renders Turdetania particularly remarkable is its excellent mines. In fact all Iberia is full of them; but Turdetania unites all the advantages of a mining country to a degree which surpasses any praise. In no country in the world do we find gold, silver, copper and iron in such quantity or of similar quality. Gold is obtained not only from the mines but also from the rivers and streams, in which it is contained mixed with sand. It is also to be found in many dry places, but with this difference, that in these it cannot be distinguished at sight, whilst it shines when covered with the water. This is the reason why water is made to pass over sandy places, to make the particles of gold shine. Wells also are dug, and many means have been invented for separating the gold from the sand by washing, so that there are more gold washing works in the country than mines. The Gauls assert that their mines, as well those of the Cevennes as those of the Pyrenees situated on their side, are better; but, nevertheless, the mines on the Spanish side are generally more esteemed. Among the particles of gold are sometimes lumps of gold weighing half a pound, which are named *pales*, and require very little refining. In cutting stones of ore, small lumps of this metal are sometimes found. After having roasted the gold intended to be purified, by means of an aluminous earth mixed with it, the result of the operation is the alloy of gold and silver known under the name of *electrum*. It is again placed in the fire, which separates the silver, and leaves the gold pure; for this latter metal is easily fused, and is not of much hardness. It is also fused sooner by the flame of straw, which, being milder, agrees better with the nature of gold, which obeys its action, and dissolves easily, while charcoal, being stronger, consumes a great part by liquefying it too soon, and converting it into vapour. As to the beds of rivers, the particles are extracted, washed in buckets, or in wells or holes made near, and the earth is washed. The furnaces for melting silver are generally made higher, to enable the pernicious vapour of this metal to rise and be dispersed. Some mines of copper have the name of gold mines, whence it is presumed that they formerly supplied this metal.

Posidonius, in speaking of the number and excellence of these mines, uses all the exaggerations of an enthusiast. The Turdetanians, says he, use the greatest industry and labour in digging winding galleries far into the earth, and often in draining, by means of Egyptian spirals, the subterranean streams with which they meet. But their lot, he observes, is very different from that of the miners of Attica, to whom may be applied the ancient enigma, "They have not taken all that they have drawn from the earth, and they have left there what they possessed." The Turdetanians, on the contrary, draw from their mines enormous profits, since the fourth of the earth which they extract from the copper mines is pure copper; and the silver mines furnish private individuals in three days with a quantity of this metal equivalent to a Euboic talent. As to tin, according to the account of Posidonius, it is not found on the surface of the earth, as some historians assert, but it is also extracted from mines. Mines of this metal are found among the barbarous people who inhabit beyond the Lusitanians and in the Cassiterrides Islands, and tin is also brought from the British islands to Marseilles. Among the Artabri, in Gallacia, the last people of Lusitania, on the north and west, there is earth covered with a dust of silver, tin, and of the metal, known under the name of white gold, on account of its alloy with silver. This dust is brought down by the rivers, raked up by the women, and then washed by them in sieves placed upon baskets. This is what Posidonius says as to the mines of Iberia.

Polybius, in speaking of those of silver which exist near New Carthage (Carthagena) says that they are 20 stades from the city, that they are so great that they extend over a district of 400 stades in circumference, that they habitually employ 40,000 workmen, whose labour brings to the Roman people 25,000 drachms per day (about £350,000 per annum). I do not enter into the detail of all the other operations, which would be too long, I confine myself to what Polybius says as to the manner in which the silver is treated, which is contained in the rivers and torrents. After having pounded and sifted it over water, what remains is separated from the water and pounded again; after having been sifted again, it is pounded and sifted five times in all. After this the pulverized matter is melted to separate the lead contained in it, and the silver remains pure. These mines of silver still exist, but there and elsewhere they belong to the state no longer, but have been taken possession of by private individuals; those of gold on the contrary mostly belong to the state. Here as well as at Castalon (Caslona) and in other places are mines of lead, which contain silver, but in too small quantity to defray the expense of separation.

* B. 3, ch. 2.

A little way from Castalon is the mountain whence the Betis (Guadalquivir) springs; it is named the Silver Mountain, on account of the mines of that metal which it contains.*

Lusitania is watered by great and small rivers which contain many grains of gold. Although the country abounds in gold, the inhabitants preferred living by plunder.†

The mountains in the neighbourhood of Malacca (Malaga) contain in several places mines of gold and other metals.

Not far from Dianium (Denia) are very fine forges.‡

WORKS IN SPAIN.

In the neighbourhood of Asta (Mesa de Asta), Nebrissa (Lebrisa), Onoba (Gibraleon), are canals dug in several places to facilitate the navigation.§

Near Cadiz is to be seen the Tower of Cæpio built on a rock, washed on every side by the sea. This admirable work was constructed in imitation of the Pharos of Alexandria.‖

SCILLY ISLANDS.

The inhabitants trade in the tin and lead which they dig from their mines. Publius Crassus, who went there, found that their mines are not very deep.

WORKS IN GAUL.

The extracts which follow are from various books.

Marius, perceiving that the mouth of the Rhone was becoming gradually shoaled up, had a new channel dug, which received the greater part of the waters. This canal he gave to the Marseillese in recompense for their service in the wars, and it became to them a great source of riches on account of the dues which they levied on those who went up or down.¶

The road from Iberia to Italy passes through Nimes. It is good enough in summer, but very bad in winter and spring, on account of the rivers overflowing and depositing mud. This road passes several rivers by boats, or by bridges of stone or wood.**

The territory of the Cevennes abounds with gold mines.††

The Tarbelli, a people of Aquitaine, are in possession of the most esteemed gold mines; for without digging deep, lumps of gold as big as the hand are sometimes found, requiring only a slight washing. The rest of the mine consists of grains and lumps, which do not either require much work.‡‡

BRITAIN.

Britain produces gold, silver, and iron.§§

LIPARI.

Lipari has very productive mines of alum.‖‖

ROMAN ROADS AND BRIDGES.

The Romans, says Strabo, have principally employed themselves upon what the Greeks have neglected—I mean paved roads, aqueducts, and those sewers which drain the city of Rome. In fact, by cutting through mountains and filling up vallies, they have every where throughout the country made paved roads, which serve to convey from one place to another the goods brought by sea to the ports. The sewers of Rome, arched with dressed stone, are broad enough in some places for a cart laden with hay to pass; and the aqueducts bring water in such abundance as to form streams running across the city, cleansing the sewers, and are sufficient, as it may be said, to supply all the houses with great fountains, canals and reservoirs. This last advantage is principally owing to the cares of Marcus Agrippa, who has decorated Rome with many other public monuments.¶¶

The principal of the great roads which traverse the country are the Appian Way, the Latin way, and the Valerian Way.***

According to modern accounts, the Valerian way was about 100 miles long; for the first 15 miles are found ruins of bridges, causeways, &c. Beyond, the remains of it are not so evident, but the boldness with which it is carried across three mountain chains is surprising.

Near the city of Como, to master the people disposed to robbery, roads have been constructed, which are as practicable as it is possible for art to make them. Augustus, not content with clearing the roads of the banditti, has made them as convenient as possible, although the country is very difficult.†††

M. Emilius Scaurus constructed the Emilian Way running to Sabbata and Darthon; and there is another Emilian Way, which continues the Flaminian Way, and was the work of M. Emilius Lepidus, colleague of C. Flaminius.* (This is an error of Strabo's, for attributing the Flaminian way to this Flaminius.)

The Salarian Way is a great road very short.† To it joins the Nomentan Way.

The Appian Way is paved from Rome to Brundisium (Brindisi), and is the most frequented of all the roads made in Italy. Beyond Terracina on the Roman side, the Appian way is bordered by a canal, which receives the water of the marshes and rivers. It is particularly by night that this way of the canal is preferred; upon it people embark in the evening, and leave it in the morning, and take for the rest of the journey, the Appian Way, but even in the day-time the boats are towed by mules.‡

Near Baiæ is an isthmus of a few stades, through which a road is tunnelled. Near Naples is a similar one, which, in the space of several stades, crosses the mountain situated between Neapolis and Dicearchia. Its breadth is such that carriages which meet find no difficulty, and light is admitted by several openings pierced internally from the surface of the mountain through a great thickness.§

The Aternus (Pescara) in the country of the Peligni is passed by a bridge 24 stades from Corfinium.‖

CANALS.

The greater part of Transpadane Italy is full of lagunes, and therefore the inhabitants have made canals and dykes as in Lower Egypt, a part of the inundated ground being drained and the rest navigable.

Epiterpum, Concordia, Atria, Vicetia, and some other small places in the neighbourhood of Ravenna, by small navigable canals communicate with the sea.

The Cispadane was for a long time covered by marshes, which arose from the superabundance of the waters of the Po, but Scaurus, by having navigable canals dug from Placentia to Parma, drained the plain.

Ravenna is a great city built on piles in the midst of the marshes, and intersected with canals, which are crossed by boats or bridges.¶

DYKE.

The Locrine Gulf in its breadth extends as far as Baiæ, and is separated from the external sea, in a length of 8 stades by a dyke broad enough for a great waggon to pass. This dyke it is said is the work of Hercules; as in rough weather the waves flowed over it, so as to make it impassable for foot-passengers, Agrippa had it raised higher.**

TIMBER.

From Tyrrhenia (Tuscany) is obtained timber for building, of which is made very long and straight beams.

Pisa supplies timber for building much used by the Romans.††

CEMENT.

Dicearchia or Puteoli has become a place of great trade, on account of the works by which it is sheltered, having in the sand of the neighbourhood (puzzolana) great facilities for such constructions. This sand employed in a certain proportion with lime, makes a body, and becomes very solid.‡‡

MINES AND QUARRIES.

The Salassi have gold mines, the working of which was facilitated by the Durias (Doria) which supplied the water required for the washings; so that, by diverting the courses by numerous branches, they often dried up the main bed, which was the cause of constant war with the neighbouring people, whose agriculture was affected. The Salassi, although conquered by the Romans and dispossessed of their mines, being masters of the mountains, continued to sell water to the mine contractors.

Polybius relates that in his time among the Taurisci Norici, (people of Corinthia, Istria, &c.) were mines of gold so rich that by digging the ground only two feet deep gold was met with, and that the ordinary works were not more than fifteen feet deep; that a part was native gold, in grains the size of a bean or a lupine, which in the fire only diminished an eighth, and that the remainder, although requiring to be more purified still, gave a considerable product. [He adds] that the Italians having entered into agreements with the barbarians for working these mines, in the space of two months the price of gold fell throughout Italy a third, and that the Taurisci having perceived it, turned out their foreign colleagues, and sold the metal themselves. At the present day the Romans possess these mines. The rivers also, like those of Iberia, contain grains of gold, although in smaller quantity.§§

Near Acyleia (Aquileia) are mines of gold and iron easy to work.‖‖

* B. 3, ch. 2. † B. 3, ch. 3. ‡ B. 3, ch. 4. § B. 3, ch. 2. ‖ B. 3, ch. 1. ¶ B. 4, ch. 1. ** Ib. †† Ib. ‡‡ B. 4, ch. 2. §§ B. 4, ch. 5. ‖‖ B. 6, ch. 4. ¶¶ B. 5, ch. 7. *** B. 5, ch. 7. ††† B. 4, ch. 6.

Cisalpine Gaul has mines which are not worked so much as they used to be, perhaps because they produce less than those of the Transalpine Celts and of Iberia, but formerly they were worked very much, since a mine of gold was wrought even in the territory of Vercelli.*

In the territory of Populonium (Capo di Campana) are some abandoned mines, and the forges in which is wrought the iron of Elba, which, as it can only be reduced in the furnaces, is transported to the continent, as soon as it is brought out of the mine. Strabo says that the excavation of these mines grew up.†

Pithecusa (Procida) has gold mines.‡

New Luna in Tyrrhenia are the quarries of marble, white, and spotted with green, of which tables and columns are made of a single block. These quarries are so numerous and so well supplied, that they are sufficient for most of the fine works which are made at Rome and throughout Italy.

The Pisan territory has an abundance of marbles.§

Gabii near Palestrina is in the midst of the quarries most used by the Romans.

At Tibura (Tivoli) are quarries of those different kinds of stones known under the names of Tiburtines, Gabians, red stones, of which most of the Roman buildings are constructed.‖

ON THE FORMS AND PROPORTIONS OF STEAM VESSELS.

Sir—Among the numerous opinions which have been advanced, as to the causes of the failure in point of speed which has attended the voyages of the British Queen and President, a subject to which the non-arrival of the latter vessel has given a most painful interest, I have not met with one which appears at all conclusive or satisfactory. Deficiency of power is always the first reason assigned; and a writer in a professional periodical, assuming that the models of these vessels are as perfect as any in existence, has gone the length of asserting that the power necessary to produce the same speed in vessels of similar form, but different dimensions, must increase in a larger ratio than the tonnage. His first position as to the forms of the vessels could, I think, be easily proved untenable, and his conclusion tends to subvert a plain physical principle; as he would make it appear that to overcome the resistance of the water, in which the *surface* of the immersed portion of the vessel alone is concerned, requires power increasing in a greater proportion than is requisite to conquer the inertia; the latter being always directly as the *mass*. Yet similar opinions are avowed by most persons who place reliance on the popular notions prevalent respecting the models of these steamers.—The nearest approach to the true manner of considering this question which I have yet seen, is, I think, made by a correspondent signing himself E., in the number of your Journal for last January; where he remarks that of the vessels he mentions, the best have the most beam in proportion to their length; and afterwards, that more seems to depend on model than power. Taking somewhat similar ground, I shall endeavour to show that as regards the several points of speed, capacity for carrying fuel to advantage, efficient working of the paddles, good qualities as seaboats, and power of carrying sail on an emergency; one essential requisite for seagoing steamers is a good breadth of beam in proportion both to their length and depth; and out of these considerations will arise others as respects the most advantageous modifications of form in the fore and after body. On all these points I shall confine myself, as much as possible, to such remarks as arise from known facts, my intention being merely to state opinions resulting from a good deal of observation, on a subject which I do not think has ever received the attention it deserves, from those more practically interested in it than myself. The first point to which I would call attention is that of speed. In all the comparisons which I have ever seen drawn as to the relative merits of different steam vessels, the principal data have always been the power of their engines, and the sectional area of the immersed parts of their bodies; and the comparison so far as regards the latter particular has always proceeded simply on the superficial area of these sections, no regard being paid to the increased pressure of the water with an increased depth: so that supposing two vessels have their immersed sectional surfaces parallelograms severally 40 feet wide by 15 feet deep, and 30 feet wide by 20 feet deep, these giving the same result as to area, their resistances are in the abstract considered equal, and any advantage which one such vessel may have in point of speed over the other, supposing their power, speed of engines, &c. to be equal, is always referred to some supposed superiority of form in the entrance and run of the faster vessel. Such a mode of calculation is founded, I believe, on the experiments of M. Bossut, who gives as a rule that any plane surface moving with a given speed perpendicularly against a fluid, suffers a resistance equal to the weight of a column of the fluid, with a base equal to the area of the moving surface, and of such a height as a body must fall to acquire the given velocity. I have never seen the details of these experiments, nor do I know whether they are within my reach, but I feel pretty certain that the surfaces made use of must have been immersed in all cases the same depth in the fluid, and the difference of dimension must have been made in breadth only, or such results could never have been arrived at. Suppose the two above named surfaces were those of flood gates; to ascertain the pressure of water on each, 600 square feet, the common result of 40×15, and 30×20, must be multiplied into the pressure at the mean depth of each. The pressure of water at the depth of 7½ feet, the mean of 15, may be taken as 3·75 lb. per square inch; and that at 10 feet, the mean of 20, as 5 lb. These numbers multiplied into 86400 the number of square inches in each surface give the results of 325000 lb. = 145 tons 1 cwt. 88 lb. for the first named, and 432000 lb. = 192 tons 17 cwt. 6 lb. for the second, being about as 7 to 9; and yet if the rule applied to calculate the resistances of vessels be correct, these two surfaces when put in motion at the same speed, immediately have their amounts of resistance equalized, because their areas are equal!—Such a result is manifestly absurd; and as the increased pressure of water in the proportion of its depth is an established fact, I shall proceed on these premises to inquire into the manner in which these vessels would be affected by the alteration of form necessary to reduce their resistance in moving through the water. We will suppose, for simplicity of argument, that their transverse sections are uniform throughout, and that both in plan and elevation they are also parallellograms. that they are each of the length of 200 feet, and their cubic contents consequently the same, viz., 120,000 feet.

Fig 1.

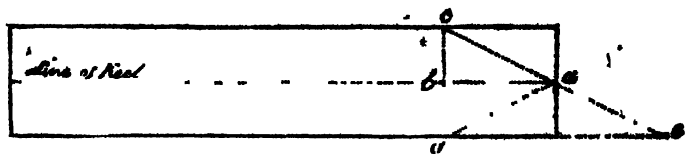

Fig 2.

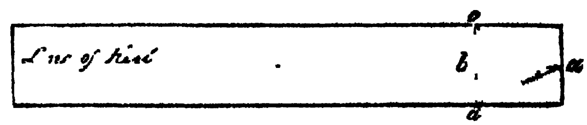

Suppose it were required to reduce their resistance by one half, preserving to the wider vessel her advantage of 7 to 9. Let fig. 1 represent the vessel of 40 feet beam, and fig. 2 that of 30. To effect the required reduction, we have simply to employ the principle of the wedge, and making *a b* in each figure equal to *c d*, in the same we have *b a*, the velocity of the vessel, equal to twice *b c*, the velocity of the weight which represents the resistance of the water to the motion of the vessel in the direction *b a*. For the weight or resistance of the whole surface *c d* is divided into two equal parts on the surfaces *a c*, *a d*, and these two halves being each moved the distance *b c* or *b d*, while the vessel moves the distance *a b*, a power is shown exactly equivalent to that of a wedge *c a e* in fig. 1. I state this thus fully because some writers on mechanics, as Emerson for example, make it appear that though the direction of the power be that of the line *a b*, it is to be calculated on the proportion which *c d* bears to *a b*, instead of that borne by *c b* or *b d*, the half of *c d*.

The vessels are thus reduced in their bulk or tonnage by the amount of a rectangular prism equal in its upper surface to the parallelogram *c b*, *b a*, and, (as we are at present considering only the immersed portion of their hulls,) of the immersed depths of each, viz., 15 feet in fig. 1, and 20 feet in fig. 2. Now *a b* is in each equal to the beam of the vessel, and *c b* equal to half *a b*, therefore the cubic contents of the parts removed are in fig. 1, $40 \times 20 \times 15 = 12{,}000$ cubic feet, and in fig. 2, $30 \times 15 \times 20 = 9000$ feet, giving a difference of 3000 feet, which divides exactly 40 times into 120,000, the total cubic contents of each vessel; thus by the sacrifice of $\frac{1}{40}$th part of the immersed portion of her body, we preserve to the vessel of greatest breadth her advantage in point of speed of 7 to 9, together with the other good qualities which I shall hereafter show to attend her proportions, by the alteration of form in the horizontal direction alone. We have next to consider how the relative merits of the two vessels will stand if it be required to give the same speed to both with the same power. Their relative resistances being as 7 to 9, we will suppose that the velocity attained by the narrower vessel with a given power is sufficient for the wider; to reduce the latter to the speed of the former, we again have recourse to the principle of the wedge, by making $a\,b$ bear the same proportion to $c\,d$, or 40 feet as 7 to 9. We thus find as $9 : 7 :: 40 : 31{\cdot}11$; then $b\,c$ 20×15 (the depth) $\times\ 31{\cdot}11 = 9333$ cubic feet, the amount by which the bulk of the wider vessel is decreased to attain the same speed as the narrow one. But the latter was shown to lose only 9000 cubic feet of her bulk by this means, and she has still therefore an advantage of 333 feet over the wide vessel, 333 will divide about 360 times into 120,000, therefore the wide vessel sacrifices 1-360th part of her bulk more than the narrow one to attain the same speed by alteration of her horizontal form; but this amount is so small as to be quite inconsiderable, for in a vessel of 2000 tons burthen the difference will be but $3\frac{1}{18}$ tons.

Thus much as to the diminution of resistance by alteration of the horizontal form; let us now inquire how the same effect may be produced by altering the vessels in their vertical section. Let fig. 1* represent the vessel of 40 feet beam, and fig. 2* that of 30, in elevation, or longitudinal section. The depth $a\,b$ equals 15 feet in fig. 1*, and 20 feet in fig. 2*. To reduce their respective resistances as before to one half, we make $b\,c$ equal to twice $a\,b$, viz., 30 feet in fig. 1*, and 40 feet in fig. 2*. They are then reduced in bulk as follows: fig. 1* by $15 \times 15 \times 40 = 9000$ cubic feet, and fig. 2* by $20 \times 20 \times 30 = 12{,}000$ cubic feet, showing a difference of 3000 cubic feet in favour of fig. 1*, being exactly what was lost when reduced in her horizontal form to give the same results. Again, to reduce the speed of fig. 1* to that of fig. 2*, make $b\,c : 30 :: 7 : 9$, thus $b\,c = 23{\cdot}33$ feet, and $\frac{23{\cdot}33}{2} \times 15 \times 40 = 6999$ cubic feet, making a difference in bulk of 5001 cubic feet in favour of fig. 1*, at the same velocity as fig. 2*. Comparing these results we see that giving the wider vessel the same speed as the narrow one, she lost 333 cubic feet more of her bulk than the latter, by doing the same by change of form vertically she has an advantage of 5001 cubic feet.* As it is almost always necessary to employ both these methods of reducing a vessel's resistance, I shall suppose them equally applied, and deducting the loss from the gain we have still 4668 cubic feet of bulk remaining for buoyancy or stowage in favour of the wider vessel when the two have the same velocity; and as the loss in preserving her advantage of 7 to 9, by change of horizontal form exactly equalled her gain in doing so by the vertical alteration, if both means are equally employed we find she preserves her advantage in speed without any loss of bulk whatever beyond the narrow vessel, and, as I think can be proved, with many points of superiority in other respects. I have considered these effects as applied to bodies of simple parallelogramic forms in the first instance for the sake of simplicity of illustration, but the principle is applicable to all forms; and as regards vessels with sharp bottoms, and of a breadth of beam say equal to the wider vessel supposed above, and of a draught equal to the narrow one, their resistance may be resolved into that of parallelograms depending in their proportions of depth and width on the acuteness or obtuseness of the angle which their bottoms make at the keel, and on the depth of their bilge or union of

Fig. 1*

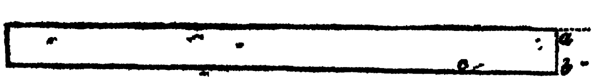

Fig. 2*.

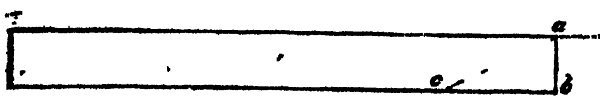

* The American river steamers referred to in the conversation at the Civil Engineer's Institution on Mr. Seaward's table of velocities, are described as diminished principally in the vertical direction; they have been aptly described as having "spoon entrances."

the sides and bottom below the water line. I shall have occasion again to refer to this part of my subject when I come to speak of the comparative stability of vessels of different transverse sections. At present I shall only remark that the results of the above calculations are fully borne out by all the seagoing steamers I am acquainted with. For instance, the Gorgon and Cyclops of 1200 tons burthen and 320 horse power, having good beam, have performed excellently; while the Liverpool, in her first state of 1042 tons burthen, and 460 horse power, through great deficiency of beam, was a miserable failure; but since her alteration, though greatly increased in tonnage by the addition of 7 feet beam, she gives more satisfactory results with the same power than any of the large steamers built for crossing the Atlantic. The Great Western registering 1840 tons, and of 450 horse power, having pretty fair beam, was the only one of the New York steamers which could be said to answer, until the Liverpool was altered, since which time the latter seems to have the advantage. The British Queen and President have completely nullified the calculations of their projectors, and Mr. Cunard's steamers, almost equally deficient in this respect, employ about 500 horse power to do what, judging from past experience, the Gorgon† and Cyclops would in all probability easily effect with 320. I think these results, independently of others which, with your permission, I shall hereafter adduce, are sufficient to prove the fallacy of the almost universal belief among shipbuilders and others that narrow vessels are necessarily faster than those of greater beam. So strongly however is this opinion held, that I know that shipbuilders of considerable experience and ability have declared that no steamer should have beam in a larger proportion to her length than as 2 to 13; or in other words should have no less than $6\frac{1}{2}$ breadths to her length; a proportion which has proved insufficient in most of the points which I named as necessary for a seagoing steamer: and for the sake of this dogma though sometimes giving their vessels very good horizontal lines, they sacrifice all the advantages they might obtain by a proper application of the reduction of body vertically, and are obliged from their want of beam, to trust to the enlargement of their bows above water to prevent their constantly shipping water forward, involving defects which I shall endeavour to make clear if I continue the subject. The subject of long narrow steamers of small draught in proportion to their beam, which have had many advocates will occupy another part of our consideration, and I refer to it here merely to say that it is not overlooked. I believe the late system of computing tonnage for shipping has had a great share in producing the defect in point of beam which is to be observed both in our sailing merchant vessels and in our mercantile steamers; for in consequence of the gross absurdity of assuming a fixed proportion of depth for every vessel, namely, half of their measured breadth, and 94 as the divisor for reducing the cubic result of the three dimensions to tons however different in form the vessels might really be. Merchants and shipbuilders universally endeavoured to gain as much as possible on their registered tonnage, by giving depth beyond the imaginary standard, and a form fore and aft which should give an absolute amount of bulk much above the $\frac{1}{94}$ths of the parallelogramic solid which were supposed, by the use of 94 as a divisor, to remain after reducing the vessel by the sharpening of her bottom, entrance, and run. This style of building has been frequently carried, as too many fatal instances have proved, far beyond the limits of safety, while vessels of really good proportions and fine form being registered by this method of a much greater tonnage than their real burthen, had an absolute fine in the shape of duty imposed on their good qualities.—In the fruit trade and others especially requiring speed, this has led to the building of deep narrow vessels sharp forward, and lean and hollow abaft, gaining somewhat in tonnage, but wanting in all really good qualities, being the wettest and most uneasy vessels which leave our ports. The numerous beautiful models which have fallen into the hands of our merchants as slave prizes have for the same reason, almost without exception, been lengthened and raised upon, have had all their fine points destroyed, been greatly reduced in speed, and frequently become exceedingly unsafe vessels, as was the case with a most beautiful slave schooner sold for the turtle trade in this port a few years ago which having been raised upon, lengthened, and square rigged, went to the bottom on her second voyage. Since the passing of the New Tonnage Act, which assigns as nearly as possible the real contents of a vessel for her register, it might have been expected that some improvement would have taken place in the models leaving the stocks in our merchant builders' yards, but so strong is habit, especially bad habit, and so rooted is prejudice, particularly in matters where expediency and not principle has been the ruling power, that hardly any use has been made of the advantages offered by the new act, and our

† See C. E. and A. Journal, vol. 1, p. 369.

newly built merchant ships, in general, present no more satisfactory aspects than their predecessors; and the proportions published as those of the new steamers building in Scotland for Government, are a further illustration of this position.† Unfortunately this defect has influenced the docks intended for the reception of merchant steamers, and unless the gates of those in this port were increased in width they would not admit steamers of the same tonnage as those now using them, but of greater beam.—Having trespassed at so great length on your space, I beg to observe in conclusion, that my reason for having cited no authority in support of my views is simply that I have met with none taking the same ground; and of those treating on this subject under any aspect, the older ones are generally very vague and general in their statements; and the more modern, though entering at great length and with much pains into particular forms, are so partial in their manner of considering the matter, that of the two whose opinions have latterly carried most weight, I have found one advocating the construction of seagoing steamers twelve times as long as they are broad, and the other predicting the time when masts and sails would be considered mere useless incumbrances, and our line-of-battle ships be used only as coal transports for steamers. Such ideas indicate any thing but a comprehensive mode of viewing this subject, and not trusting much to the assistance to be derived from such sources I have preferred merely stating the result of my own observations, relying on the candid consideration of those who are practically interested in this matter.

I am, &c.,

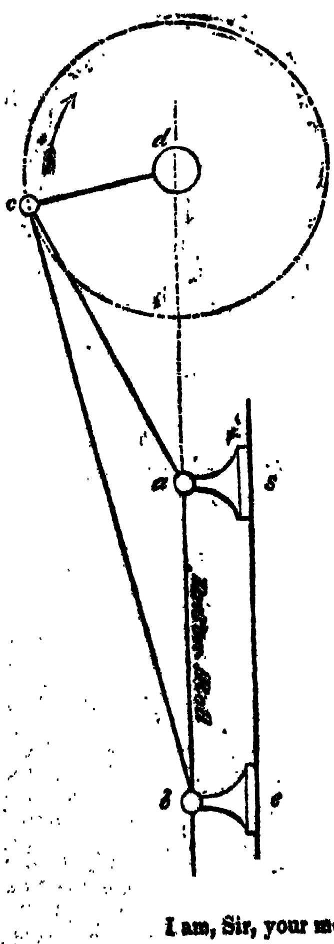
ON LONG AND SHORT CONNECTING RODS.



Sir—Perceiving in your excellent Journal for this month, an article respecting long and short connecting rods, wherein it is stated that the short connecting rod is as effective as the long one, I take leave to send you a diagram, which will perhaps show that there is a greater amount of friction with the short connecting rod.

The accompanying figure represents the direct connection with the piston of a long and short connecting rod. In this case it is clear that the long rod *c, b*, is working always nearer the *parallel line* of the piston than the short rod *c, a*, or that the short rod is pushing against the slide *s, e*, at a much greater angle than the long one, and consequently that there must be less friction at *e*, than at *s*, therefore as the angle *c, a, d*, is greater than the angle *c, b, d*, so is the friction at *s*, greater than the friction at *e*. The same results will be found with common marine and all other engines, only that where slides are used there is always a much greater amount of friction than upon centres. I am however of opinion, that a short connecting rod, with a direct connection with the crank, might be used with greater effect than a longer one in the common marine engine, where heavy side levers are kept continually reversing their motion, besides the extra weight which the boat has to carry.

I am, Sir, your most obedient servant,

J. F.

London, July 12.

Sir—In your July number you have a letter from Mr. Daniel Clark on "Long and short connecting rods," in which he arrives at the conclusion that "upon the whole, then, short and long connecting rods on the same length of crank must be equally effective, whatever peculiarities there be." In this, however, I do not concur with him and would recommend him to re-consider the subject and see if really the force (see Mr. Clark's first figure) D C or E M be of no consequence; I think he will find it to be of the greatest consequence, and to be together with the analogous force of pressure on the other journals, the reason why long connecting rods always have been and always will be preferable, and why, moreover, an engine, the connecting rod of which bears to the length of the crank a ratio less than a certain quantity, would not work at all. Mr. Clark would find it very interesting to consider minutely the case in which the length of the connecting rod is equal to the length of the crank, he will find that the strength required for the paddle-shaft, the connecting rod, all the journals, the framing, and in fact the whole engine, is what may probably startle him.

I am, Sir,

Greenock, July 5. Your obedient servant,

J. G. L.

MR. PARKES NEW THEORY OF THE PERCUSSIVE ACTION OF STEAM.

Sir—Feeling some interest in Mr. Parkes' new theory of the percussive action of steam in the Cornish engines, might I offer a few remarks on the former part of a paper which appeared in your Journal for this month. The writer of that paper appears from his remarks at the beginning, to have an opinion that Mr. Parkes has rather favoured the Cornish engines, in considering that the percussive force of steam is only developed in them; and he remarks that if such a property does exist in the steam, we might expect to find it more fully developed in the case of the locomotive engines; for he says, "though why he considers it to operate in these engines only, we know not; we are of opinion that if it obtains in them, it should obtain *à fortiori* in locomotives, where the density and velocity of the steam entering the cylinder are so much greater."

The object of the following remarks is to try to show that the Cornish single-acting engines are the only ones at present in which the percussive force of steam could act with any very great advantage; and that the locomotives are the very worst engines in which it could be used as a moving force.

We will first of all take the case of a common double-acting rotative engine. In these engines the slide is so adjusted as to let the steam into the cylinder when the piston is either at the top or bottom of its stroke; and consequently, when the crank is just passing the centre. Now this being the case, it is evident that any percussive force of the steam striking upon the piston would be injurious rather than benefit the engine, as it could not by any means have any effect in turning the crank, but, on the contrary, only create an additional wear and tear of the different working parts, on account of the violent jerk which would be the effect of its striking upon the piston while the crank is in such a position as not to let it recede before the blow. In this engine, then, as at present constructed, we must not expect to find any very great economy by bringing this force into action.

In consequence of the rapidity with which the strokes of the piston in a locomotive follow one another, it is found necessary to admit the steam into the cylinder before the piston has finished its stroke, for two reasons: 1st, it is found necessary to admit the steam into the opposite side of the piston before it has finished its stroke, in order to bring it gradually up to the stop, and to diminish the violent jerk that would be occasioned by its motion being so rapidly changed, and 2ndly, so that it may be ready to act as soon as the piston has finished its stroke. This being the case, the percussive force of steam would act still worse here than in the before-mentioned case, as it would, instead of helping to impel the piston, actually impede it, if not stop it altogether. In this case, as well as in the former, the percussive action is altogether avoided by the gradual motion of the slide, for as soon as the slide begins to open the steam way, the steam rushes into the cylinder and strikes upon the piston, but with very little effect, on account of its being so much wire drawn in consequence of the small size of the opening at first.

In order to render the percussive force of steam available to its fullest extent as a moving power in single acting pumping engines, it would be necessary to have some medium interposed between the direct action of the steam on the piston and the pumps; so as to convert the ever-varying pressure on the piston into a regular and steady pressure on the plunger of the pump. This I think will be clearly seen, for if we suppose for an instant this medium not to exist, such as

* The Forth has lately arrived in Liverpool, and fully confirms the above opinion; proving with two steamers lately sent hither from Hamburg, that the examples of the Liverpool, British Queen and President have not influenced their builders in assigning the proportions of breadth and depth.

the momentum of the different parts of the engine, the pump rod, and the column of water set in motion; we must come to the conclusion that as the pressure on the piston varies without any medium to equalize its effect, the resistance opposed to the pump plunger ought to vary also.

In the common single acting pumping engine this medium is in a measure supplied by the weight of the pump rod, which is made sufficiently heavy to overcome the friction of the engine, and to raise the piston at the return stroke, and by the momentum of the beam and other parts of the engine; and also by the momentum of the column of water before it enters into the air vessel; these however would form but a very small reservoir for the immense pressure at the commencement of the stroke, so that in these engines the application of the percussive force must be very limited, in consequence of the pump rod not being of a sufficient weight to accumulate all the overplus power at the commencement of the stroke, so as to impart it to the plunger when the pressure on the piston in consequence of the expansion of the steam, falls below the resistance on the plunger so that the percussive force would be in a great measure entirely wasted. Again on the other hand, if the rod which generally weighs from 8 to 9 tons, were made heavier, so as to equalize to a great extent the pressure on the plunger, it would be more than necessary to overcome the resistance of the engine at the return stroke, and so occasion a loss of power.

The action of the Cornish single acting engine is somewhat different from that of the common one, the pressure of the steam on the piston instead of being applied directly to work the pumps, is applied to raise a pump rod of sufficient weight to work the pumps at the return stroke. The result of this difference of arrangement is that instead of having a pump rod of 8 or 9 tons weight, we get one of from 20 to 70 tons weight according to circumstances. Here then we get an immense mass of matter amply sufficient to accumulate all the overplus power at the commencement of the stroke, and to return it as required at the end of it. The action of it is this: the steam being admitted suddenly into the cylinder strikes upon the piston at rest with a considerable force above what is due to its elastic pressure alone, and sets this massive pump rod in motion; the steam in the cylinder expands, and consequently acts with less force on the piston, and the pump rod after the pressure of the steam on the piston, becomes insufficient of itself to raise it any higher, assists to carry itself through the remainder of the stroke, by means of the power that it accumulated at the commencement. When the rod is thus as it were thrown up to the top of its stroke, the equilibrium valve is opened and the weight of the pump rod descending acts upon the plunger of the pump and raises the water. In this engine then we have the means of applying the percussive force of steam to almost any extent in consequence of the weight of the pump rod, which acts as a reservoir for the power that would otherwise be wasted.

These remarks I think have clearly shown that in the common double acting engine the percussive force of steam could not be made to act with any advantage, but would, on the contrary, occasion an additional wear and tear; that in the locomotive it would act still worse, and would actually impede the engine, if not stop it altogether; that in the common single acting pumping engine it could only be brought into useful action in a small degree; and that in the Cornish engine we might use it as a moving force to a very considerable extent.

When we consider the amazing quantity of work done by the Cornish engines as compared to any other, we are perfectly at a loss to account for the difference, and are brought to the conclusion that there must be some force in the steam which can only be applied to any considerable extent in those engines, and which will not allow of being so applied in any others. The elastic force of steam can be applied in any sort of engine, the expansive force can be applied economically in all, but more so in the Cornish than any other engines; but still this is insufficient to account for the difference of the amount of duty done. The only other force that we can conceive the steam to possess is that which Mr. Parkes has denominated its percussive force. If the conclusion drawn from the preceding remarks be just, we see that the Cornish engines are the only ones in which this force could be applied to any considerable extent.

It also stands to reason that if this force does exist in the steam, and if it was usefully applied it would increase very considerably the duty done. It is also now a fact well ascertained that the Cornish engines will do three times the duty of any other with the same expenditure of fuel.

Is it not then reasonable to infer that as the Cornish engines are the only ones in which the percussive action could be employed to any considerable extent, and that they alone perform that additional work that would be the effect of this force if usefully applied, we may safely conclude (if all other evidence was wanting), that this percussive force does actually exist in the steam, and that it is in a great measure to account for the quantity of work done by these engines.

Hoping that these observations may help to throw a little light on the subject, and may induce some of your readers who may have the means, to pay a little attention to the subject.

I remain, Sir, your's, respectfully,

C. S.

Bankside, Southwark,
August 13, 1841.

ON THE MOMENTUM PROPOSED BY MR. JOSIAH PARKES AS A MEASURE OF THE MECHANICAL EFFECT OF LOCOMOTIVE ENGINES.

By the Count De Pambour.

In the *Transactions of the Institution of Civil Engineers*, vol. III, Mr. J. Parkes has published a paper *On Steam-boilers and Steam-engines*, in which the object is to propose, as a new measure of the mechanical effect of locomotive engines, what he calls the *momentum* produced by the engine, that is to say the product of the mass, in tons, of the engine, tender and train, multiplied into its velocity, in feet per second. According to him, this momentum being measured at one velocity, for a given engine, the effect of the same engine, at any other velocity, will be immediately deduced from it by a single proportion (page 130), without troubling one's head about the inclination of the road, the friction of the wagons or the engine, the counter-pressure due to the blast-pipe, the resistance of the air, or, in fact, any of the resistances really encountered by the engines.

To establish this new idea, Mr. Parkes' first step is to represent as altogether faulty and impossible every calculation or experiment made by others, to take account of the divers resistances offered to the motion of the engines. With this view he enters into a long and malevolent discussion on the experiments of our *Treatise on Locomotive Engines*, and on all the experiments on the same subject published by different engineers; and to demonstrate the difficulties insurmountable, in his opinion (page 124, 129), and the uncertainty attending such researches, he indicates several verifications which, as he says, these experiments ought to satisfy, and which they do not satisfy. As Mr. Parkes gives on the subject a great number of arithmetical calculations, the errors of which are protected against detection by the heap of figures presented, we shall first enter, with some detail, the examination of his pretended verifications, and afterwards shall discuss the value of the new measure proposed by him to represent the mechanical effect of locomotive engines.

On seeing the *fundamental* errors on which his reasoning and his calculations are grounded, the inaccuracy of his criticisms and of the results at which he has arrived, will be at once recognised.

1st. Mr. Parkes proposes to calculate the pressure at which the steam was necessarily expended on the cylinder of each engine submitted to experiment, in order afterwards to compare that pressure with the pressure resulting from the sum of the different determinations of resistances exerted against the piston, according to the *treatise on locomotive engines*. With this view, he seeks, from the velocity of the engine, the number of cylinders full of steam which were expended per minute. Comparing the volume thus obtained to the volume of water vaporized in the boiler, he concludes the *relative* volume of the steam during its passage into the cylinder; and finally, recurring to the table of the relative volumes of steam under divers pressures, contained in our *Theory of the Steam Engine*, he concludes the pressure which the steam must necessarily have had (page 82, &c.) This is conformable to our theory developed in the *Treatise on Locomotive Engines*, which, in fact, Mr. Parkes entirely adopts. But to perform this calculation, Mr. Parkes takes the *average* velocity of the whole trip from Liverpool to Manchester (page 85, and table viii., col. 10; table xiii., col. 9; table xvi., col. 2, &c.), and from that velocity he pretends to deduce the *mean pressure* of the steam in the cylinder during the same trip. Now it will be easy to prove by an example that this mode is altogether faulty.

Suppose, in effect, the engine Atlas has travelled a distance of [illegible] miles in an hour and a half, vaporising 60 cubic feet of water per hour. As the wheel of the engine is 5 feet in diameter, or 15·71 in circumference, as there are two double cylinders-full of steam expended at every turn of the wheel, and as the capacity of those two double cylinders, including the filling up of the steam ways, amounts to [illegible] cubic feet, it follows that the volume of the steam which passed into the cylinders per mile performed, or per distance of 5280 feet, is

$$\frac{5280}{15 \cdot 71} \times 4 \cdot 398 = 1478 \text{ cubic feet.}$$

This premised, when Mr. Parkes refers to the average velocity of the whole trip, to value the pressure in the cylinder, as that velocity is 20 miles per hour, and as the vaporization at the same time is 60 cubic feet of water per hour, he finds, for the ratio of the volume of the steam expended to the volume of water, $\frac{1478 \times 20}{60} = 492 \cdot 7$. Consequently, recurring to the table of the relative volumes of steam under different pressures, he obtains for the corresponding total or absolute pressure 56·66 lb. per square inch; and deducting the atmospheric pressure, he obtains for the effective pressure, 41·95 lb. per square inch.

But to show that this mode of calculating, from the average velocity, can only lead to error, let us suppose that, by reason of the divers inclinations of the portions of the railway, the first 15 miles have been traversed in half an hour, and the other 15 miles in an hour, which still makes 30 miles in an hour and a half; as 30 cubic feet of water will have been vaporized in the first half hour, or during the passage of the first 15 miles, and 60 cubic feet of water during the next hour, or in the passage of the last 15 miles, it is plain that the volume of the steam will have been respectively in each of those times $\frac{1478 \times 15}{30} = 789$ first, and afterwards $\frac{1478 \times 15}{60} = 369 \cdot 5$. Whence results, according to the table, that the effective pressure of the steam will have been successively 21·62 and 62·95 lb. per square inch.

Thus, during the first half hour the effective pressure will have been 21·62 lb.; during the second half hour it will have been 62·95 lb., and during the third again 62·95 lb. Consequently, taking account of the time during which the pressure has had these respective values, it is plain that the mean effective pressure in the cylinder will really have been $\frac{21 \cdot 62 + 62 \cdot 95 + 62 \cdot 95}{3} = 49 \cdot 17$ lb. per square inch, and not 41 95 lb. per square inch, as given in Mr. Parkes's calculation; which, by the fact, supposes all the portions of the trip to have been performed in equal times. In this case, therefore, which has nothing in it but what is very ordinary, there would be an error of 7·22 lb. per square inch out of 41·95; that is an error of more than $\frac{1}{6}$ on the effective pressure of the steam. It is evident that the calculation, such as Mr. Parkes makes it, is exact only for portions of road composed of one inclination, or travelled with *uniform* velocity, and that it cannot apply to the total passage of a line composed of different inclinations. For further elucidation on this head, we refer to chapter XVII., relative to inclined planes, of our *Treatise on Locomotive Engines*, 2nd edition, and to chapter XII. of the same work, in which all the experiments considered by Mr. Parkes are calculated.

2nd. We have just shown the first error which Mr. Parkes introduces, as a fundamental basis, in his calculation of the pressure of the steam in the cylinder. But he does not stop there. In the table of experiments on the vaporization of the engines (*Treatise on Locomotive Engines*, page 175 of first edition, and page 253 of second edition), we have given the average velocity of the engines during each trip; and that velocity is obtained simply by dividing the whole distance performed, by the time employed in performing it, as is seen in the table in question. It would be natural then for Mr. Parkes, who, as has been said, is satisfied with average velocities in his calculations, to take those which are given in the table; but instead of that, he augments almost all the velocities about $\frac{1}{6}$. Thus, for instance, the VULCAN, which travelled 29·5 miles in 1 hour 17 minutes, and whose average velocity in consequence was stated to be 22·99 miles per hour, had, according to Mr. Parkes, a velocity of 26·90 miles per hour. The velocity of the VESTA rises from 27·23 to 31·60 miles per hour, and so of the others (table viii., col. 10; table xiii., col. 9; table xvi., col. 2). The critic falls into this new error because, in the *Treatise on Locomotive Engines* (page 324 first edition, and page 311 second edition), in speaking of fuel, it is said that, when the engines ascend without help the inclined planes of the Liverpool and Manchester Railway, the surplus of work, thence resulting for them, equals, on an average, the conveying of their load to $\frac{1}{6}$ more distance, and Mr. Parkes logically concludes from this that the *velocity* of the engine must be by so much increased (pages 86, 112). So that if an engine perform 1 mile in 4 minutes, ascending a plane inclined $\frac{1}{96}$, which renders nearly five-fold the work of the engine, it would follow, from this calculation, that the velocity would not have been 15 miles per hour, but $15 \times 5 = 75$ miles per hour, since the quantity of work done would have been five-fold! Mr. Parkes's error proceeds from his having applied to the velocity a correction which refers only to the *work* done, and, as a consequence, to the corresponding consumption of *fuel*.

But on examining what effect results from this substitution of the imagined velocity of Mr. Parkes for the observed velocity, it will be remarked that whenever an engine is obliged to ascend without help one of the inclined planes of the Liverpool and Manchester Railway, it exerts at that moment, as we have said, an effort five times as great as upon a level, and draws its load less rapidly. One would deem it then allowable to conclude, that the average pressure of the steam in the cylinder must be augmented, since during a certain portion of the trip, the effort required is greater, and that the *useful* effect per unit of time must be diminished, since during the same time the useful load is drawn at less velocity. But no. Mr. Parkes's calculation, by augmenting, then, the apparent velocity of the engine, demonstrates that, in this case, the average pressure in the cylinder becomes on the contrary much *less*, and that the useful effect becomes much *greater*. So that the error committed produces itself here in the two opposite ways.

With these elements Mr. Parkes establishes the *whole* of his calculations and tables, to the very end of his paper (table viii., col. 10 table ix., col. 19; table xiii., col. 9; table xiv., col. 2; table xvi., col. 2) and as, to augment the evil, this pretended correction is made only on one portion of the experiments, namely those in which the engines were helped up the inclined planes, without being made in the other cases, there results an inexplicable confusion in all the calculations. Thus, it happens that Mr. Parkes's determination of the volume and pressure of the steam consumed by the engines (table ix., col. 26, 29) the horse power produced per cubic foot of water vaporized, or the quantity of water employed to produce one horse power (table x., col 44, 45, 49, &c.), the momentum generated per pound (table xiii., col 11, 12; table xiv., col. 9, 10, 11), and all the consequences thence derived are in every way erroneous.

To show by a particular example, the fallacy of the results to which Mr. Parkes has been led by this wholesale and faulty way of calculating, we need only refer to the two experiments of the FURY, which he extracts from our work on locomotive engines. He pronounces, "with certainty," (page 128), these two experiments to be erroneous, as exhibiting an engine performing more work at 23 than at $21\frac{3}{4}$ miles per hour, in the ratio of 21 to 19. Now, to arrive at this conclusion, Mr Parkes first takes the velocity of the engine, not at 18·63 and 19·6[illegible] miles per hour, as given from actual observation, page 175 of the first edition, and pages 253 and 392 of the second edition of our Treatise on Locomotive Engines, but at 21·79 and 23 miles per hour (table xiii, col. 3). Secondly, in comparing the work done in the two trips, he does not take into account that the first of the two trips has been made from Manchester to Liverpool, and the second on the contrary from Liverpool to Manchester. But there is a general rise of the ground from Manchester towards Liverpool, and from that circumstance, the gravity opposes more resistance in that direction than in the contrary one. Thus it happens that a less train carried on the line from Manchester to Liverpool, may require from the engine, a greater quantity of labour than a heavier train carried in the opposite way. In effect by referring to pages 501 and 504 of the second edition of our work on locomotives, it will be found that in the two experiments under consideration, the work done by the FURY, in carrying the two loads of 43·8 and 51·16 tons, besides tender, from Manchester and from Liverpool respectively, to the other end of the line, was

43·8 tons, from Manchester to Liverpool, equal,
gravity included, to - - - 1964 tons to 1 mile
51·16 tons, from Liverpool to Manchester, equal,
gravity included, to - - - 1837 tons to 1 mile

We see, therefore, that when we take an account, as we ought to do, and as Mr. Parkes has not done, of the surplus of labour caused by gravity, the work required of the engine is in reality more in the first case than in the second, although the load itself is less. Consequently the engine ought to have accomplished the second trip in less time or with a greater average velocity than the first, which in fact it did, and which had led Mr. Parkes to pronounce with such "certainty" the experiments to be erroneous.

This example shows that the calculation of Mr. Parkes, made with an erroneously averaged and exaggerated velocity, in which, moreover, he omits the gravity on the inclined planes, the resistance of the air, the friction of the engine, and all the other resistances really opposed to the motion, leads him to a *very inaccurate* measure of the work performed by those engines; and this refers to the whole of the results obtained, table ix., col. 29—32; table x., col. 41—50; table xiii., col. 11, 12; table xiv., col. 9, 10, 11; table xvi., &c., and also to his comparison of locomotive and stationary steam engines, which we shall notice further on.

3rd. After having calculated *very exactly*, as we have shown, the pressure of the steam in the cylinder, Mr. Parkes compares the result which he has obtained, with the total pressure on the piston resulting from the partial resistances suffered by the engine, according to the *Treatise on Locomotive Engines*; and as, in the first edition of that work, the author had confined himself to mentioning the pressure against the piston due to the action of the blast-pipe, without making any experimental research on the subject, Mr. Parkes, without noticing the results presented since in the *theory of the steam engine*, (page 161), takes the difference between the two results, as necessarily expressing the pressure due to the blast-pipe (pages 82, 83); and he demonstrates the inaccuracy of it. *Here we perfectly agree with him; for*, besides the errors already pointed out in his research of the pressure of the steam in the cylinder, every thing variable that can occur in the different data of resistance, now passes to the account of the pressure due to the blast-pipe, and must necessarily come to falsify the calculation of it. Thus, for instance, in the experiments, a great deal of water was lost by *priming*, and there resulted an apparent vaporization greater than the true one. A part of the difference between the calculated and the observed pressure was therefore to be attributed to that cause, though it could not be accurately measured; but, by the calculation of Mr. Parkes, it all passes to the account of the pressure due to the blast-pipe. Similarly, the resistance of the air, then imperfectly computed in the total resistance for an average velocity of about 12 miles per hour, is found, in all cases of greater velocity, to augment considerably the pressure due to the blast-pipe, and on the contrary to diminish it in all cases of less velocity. A favourable or an unfavourable wind necessarily produce similar effects. Thus, circumstances, combined with the fundamental errors already introduced in the calculation, raise or lower that pressure to all imaginable degrees (pages 87, 88, 90, 91); and it will be readily imagined that such a determination cannot be exact.

4th. Mr. Parkes has observed, in the experiments of the *Treatise on Locomotive Engines*, and particularly in two of them, made with the LEEDS engine, and quoted in the *Theory of the Steam Engine*, that the useful effects produced by the same quantity of water vaporized varies according to different circumstances, and he is amazed at it; for, as he affirms, the useful effects produced by the same quantity of water vaporized, in the same time and under the same pressure in the boiler, ought in all cases to be identical (pages 104, 119). But this again is merely an error of the critic; for if we suppose a locomotive engine drawing a heavy load at a small velocity, since it is only at a small velocity that the engine has to overcome its friction, as well as the atmospheric pressure against the piston, and, above all, the resistance of the air against the train, it follows that out of the quantity of total work executed, there will be but a trifling portion lost in overcoming those resistances; but if, on the contrary, we suppose the same engine performing precisely the same quantity of *total* work, but drawing a light load at a great velocity, it is obvious that a much greater part of the work done will be absorbed in moving, at that velocity, the resistance which represents the friction of the engine, as well as the atmospheric pressure against the piston, and in overcoming the resistance of the air, which increases as the square of the velocity; and consequently there will remain a much smaller portion of it applied to the producing of the useful effect. Hence, in the two cases considered, the useful effects produced by the same quantity of water vaporized, so far from being identical, will, on the contrary, be very different from each other. Mr. Parkes may, besides, satisfy himself on this point, by perusing the *Theory of the Steam Engine*, in which he will find numerous examples of steam engines, in which the useful effect of one cubic foot of water varies in very wide limits, according to the velocity of the motion or the load imposed on the engine; and he will find it explained theoretically in chapter XII. of the *Treatise on Locomotive Engines*, or in chapter III. art. 11, of the *Theory of the Steam Engine*. Thus Mr. Parkes's reasoning errs again by the basis itself.

5th. But there is another principle to which Mr. Parkes would subject all the observations of vaporization of locomotive engines. He remarks that in the two experiments above cited, the total resistance opposed to the motion is different in the two cases. Consequently, says he, the quantities of water vaporized by the engine in the same time must be in proportion to the pressures in the cylinder, and the experiments ought to satisfy this condition (pages 99, 100). Upon this point he is merciless.

To establish this new principle, Mr. Parkes recurs to the *Treatise on Locomotive Engines* itself. He quotes a passage in which, supposing same engine travelling the same distance with two different loads, the author says positively that the distance travelled being the same in both cases, the number of turns of the wheel, and consequently the number of strokes of the piston given by the engine, that is to say, the number of cylinders full of steam, or finally the total volume of steam expended, will also be the same in both cases; whence results that the same volume will successively have been filled with two steams at different pressures, or in other words, at different densities; and consequently the quantities of water which have served to form those steams will be in proportion to their respective pressures (page 310—312 of the first edition). Thus, this passage establishes very distinctly that the quantities of water vaporized, *for the same distance*, are in proportion to the pressures of the steam in the cylinders. But what does Mr. Parkes conclude from this? Why, that the quantities of water vaporized *in the same distance* are in proportion to the pressures in the cylinder. Now it happens to be just the contrary; for, if we suppose, by way of example, the two pressures to be in the ratio of 2 to 1, the volumes of water vaporized for the same distance traversed, will also be in the ratio of 2 to 1; but if the time employed in performing the distance in question be two hours in the first case, and one hour in the second, it is plainly the quantities of water vaporized in two hours and in one hour respectively, which will be one to the other in the ratio of 2 to 1, so that the vaporizations per hour, or *in the same time*, will be equal instead of being in the ratio of the pressures. Thus it is clear again that Mr. Parkes's principle rests but on a new error, which consists in making a confusion between the vaporization for the same distance and the vaporization for the same time.

6th. A final observation of Mr. Parkes (pages 89, 90, 98), is this, that in some experiments, the locomotive engines produced, for the same quantity of water vaporized, a greater useful effect than several stationary high-pressure steam engines, or even than several condensing steam engines; and he considers this result as a proof of the inaccuracy of those observations; for, says he, the locomotive engines having to contend with the pressure arising from the blast-pipe, which the high pressure engines have not, and also with the atmospheric pressure, neither of which resistances the condensing engines have to contend with, it is incontestable that they cannot even produce equal effects, much less superior ones (page 104). But this reasoning is as unfounded as those we have already noticed; for, since the useful effect of steam engines, for the same vaporization, diminishes as the velocity of the motion increases, which has been already explained above, and which is found developed, either in chapter XII. article II. of the *Treatise on Locomotive Engines*, second edition, or in chapter III. article II., section 1, of the *Theory of the Steam Engine*, it is easy to conceive that a locomotive working, for instance, at its maximum useful effect, that is to say, with its maximum load, and consequently at a very small velocity, at which the pressure due to the blast-pipe and the resistance of the air are nearly null, can produce a useful effect greater, nay much greater than a stationary high pressure engine, working on the contrary with a light load and a great velocity. The same inferiority of effect may also occur in a condensing engine, because an engine of that system working, for instance, at 16 lb. pressure per square inch in the cylinder, and condensing the steam to 4 lb. per square inch *under the piston*, where the pressure is always greater than in the condenser, loses, by that fact alone, a quarter of the power which it applies; whereas a locomotive, working at 5 atmospheres in the cylinder, and at a very small velocity, which renders almost null the pressure due to the blast-pipe, suffers, by the opposition of the atmospheric pressure, a loss equal to only $\frac{1}{5}$ of its total power. Hence, definitively, in the latter engine, the counter-pressure against the piston destroys a smaller portion of the total power applied, and consequently, without even noticing the difference of friction of the two engines, or entering into any other consideration relative to the velocity, it is conceivable that the useful effect of the locomotive may be found greater.

But if a more complete calculation be desired, it will be easy to furnish it; for the relative volume of the steam at 16 lb. pressure per square inch, being 1672 times that of water, it is plain that if S represent the number of cubic feet of water vaporized per minute in the boiler, and if a represent the area of the cylinder expressed in square feet, 1672 S will be the volume of the steam generated per minute whence results that $\frac{1672\,S}{a}$ will be the velocity, in feet per minute, assumed by the piston of the engine working at that pressure. Moreover, the *effective* pressure of the steam or the load which the piston can support, is $16 - 4 = 12$ lb. per square inch; which gives $12 \times 144\,a$ for the total resistance, in pounds, supported by the piston. Thus, in the condensing engine, the effect produced by the number S of cubic feet of water, expressed in pounds raised one foot per minute, is $1672 \times 12 \times 144\,S = 2{,}889{,}216\,S$. Calculating in the same manner the case of the locomotive engine, we find that the effect it produces for the same vaporization S, working at the total pressure of 75 lb. per square inch, or at the effective pressure of 60 lb. per square inch, and expressed in pounds raised 1 foot per minute, is $381 \times 60 \times 144\,S = 3{,}291{,}840\,S$. Therefore, finally, its useful effect, per cubic foot of water vaporised, will exceed that of the condensing engine, and this again is a circumstance, examples of which will be found in the *Theory of the Steam Engine*.

Thus this new peremptory condition which the experiments ought to satisfy is as unfounded as the former ones; and, in fact, Mr. Parkes contradicts it, himself, a little further on (pages 157, 158), so that we might have referred his first argument to his second, for refutation. But, besides the foregoing observations it must be borne in mind that the velocities employed by Mr. Parkes, for locomotive engines, being nearly all considerably augmented, as has been explained above, he must necessarily arrive (pages 85, 87, 89, 92, and tables x., xiii., xiv., xvi.), at exaggerated results, for the effects which he supposes to have been produced by those engines; and therefore his comparison between locomotive and stationary engines, is altogether founded upon false calculations.

It is remarkable, finally, that in applying the preceding considerations to all the experiments published on locomotive engines, by different engineers, namely, Messrs. R. Stephenson, N. Wood, E. Woods, and Dr. Lardner (pages 102, 117, 118, 159), Mr. Parkes finds that the conditions to which he proposes to subject those experiments are not verified in them. Such a result ought to have put him on his guard against the validity of his own arguments; but the want of knowledge in the principles of Mechanics and of habit in mathematical reasoning (the author tells us that he is more accustomed to handle the hammer than the pen), causes him to heap errors on errors, combining and complicating them unawares, till he arrives at a point where he does not produce a single result that is not erroneous.

There is a matter of surprise in the numberless errors contained in the paper of Mr. Parkes, and of which, for the sake of brevity, we have noticed merely the principal ones, reserving the rest for another opportunity if necessary. But on inquiring what was the end he had proposed to himself, what was to be definitive consequence of his labour, one is yet much more surprised.

His object is to propose a new measure of the effect of locomotive engines; and this *new* measure is what he calls the "momentum" generated, that is to say, "the product of the mass, in tons, of the engines, tender and train, multiplied into its velocity, in feet per second." This standard is to "represent the repective mechanical effect produced per second by each engine" (page 128).

Now, the true mechanical produce includes the whole of the resistances and frictions really overcome by the engines; that is to say, the friction of the carriages, the friction of the engines, the gravity of the mass on the different inclines traversed, the atmospheric pressure, the pressure due to the blast-pipe, the resistance of the air, &c.; and in multiplying the sum of all these resistances, by the velocity of the motion, we shall have the mechanical effect produced. But, if among all those divers resistances, we take account *only* of the friction of the carriage, and the engine, omitting all the rest, and if we suppose, for an instant, that friction to be 6 lb. per ton, as well for the engine as for any other carriage, we shall have the effect produced, in multiplying the weight of the train, tender and engine included, first by 6 lb., and afterwards by the velocity of the motion. Now, it is evident that in calculating thus, we shall have exactly the same number given by the computation of Mr. Parkes, excepting that all of them shall be multiplied by 6. Therefore, the new measure proposed comes merely to this, that the effect of the engines will be calculated by the friction of the carriages only, and that of the engine considered as a mere wagon, and the results divided by 6.

But, as this pretended "standard" comprehends only a portion of the resistances really overcome; as it does not include the gravity of the train, which may, according to circumstances, offer a resistance exceedingly great, or null, or even act in favour of the motion; as it does not include the counter-pressure due to the blast-pipe, which varies according to the velocity, the rate of vaporization and the size of blast-pipe; as it does not include the total friction of the engine, but only the friction of its wheels, as a single wagon; as, above all, it does not include the resistance of the air, which, from experiments of which Mr. Parkes is "utterly ignorant" (page 124), varies according to the bulk of the train and the square of the velocity, so that the quantity neglected, on that account, in the calculation may, at times, be quite trifling, and at other times, exceed the *momentum* of Mr. Parkes itself; as in fact this pretended *new* measure is nothing more or less than the common *useful effect* of the engine, as given in many works and particularly in our *Theory of the Steam Engine*, and *Treatise on Locomotive Engines*, with these differences only that in Mr. Parkes's calculation, it includes also the weight of the engine, and that it is erroneously computed, inasmuch as, in multiplying the weight of the train, in tons, by the velocity, the calculation is made as if the whole weight were raised up in the air by the engines, instead of being dragged or rolled along the rails; as, finally, this pretended standard, instead of being constant, varies with the velocity, just as well as what Mr. Parkes calls the *commercial* and *useful* effects, so that it is not more easy to know the one than the others, or that the rule of Mr. Parkes, which we are going to quote, refers to the one just as well as to the others; for all those reasons, then, we see that the aforesaid measure is not new, that it does not measure the mechanical effects of the engines, and finally that it is nothing more or less than the common useful effect (weight of engine included), calculated in considering the whole train raised up in the air and the engine as a mere wagon.

After having thus found upon *reasoning* the accuracy of his new measure of the mechanical effect of the engines, Mr. Parkes proceeds to show the "powers of this method of analysis" (page 131). Collecting all the erroneous results which he has obtained in his tables, and admitting then, as accurate, the experiments of the *Treatise on Locomotive Engines*, which he thought of demonstrating false before, Mr. Parkes forms a table in which he sets in view, on one side, the vaporization effected by the engine, and on the other side the useful effect produced, giving it only the name of *momentum* when it includes the weight of the engine besides that of the wagons. Then comparing the vaporization to the effect produced, and taking an average, not upon his own experiments, *since he has made none*, but upon all the experiments which he has collected from the divers works published on the subject, he presents (page 130), as the result of his labours, the following conclusion, which he proposes to substitute in place of every other kind of research on locomotive engines.

When the velocity of a locomotive engine is augmented in the proportion of 1·52 to 1, the vaporization necessary to produce the same effects varies in the following proportions:

To produce an equal *momentum* (an equal useful effect, weight of wagons and engine included), in the proportion of 1·42 to 1, or in a proportion something less than that of the velocities; to produce an equal *commercial* gross effect (an equal useful effect, including the weight of the wagons), in the proportion of 2·43 to 1, or nearly as the square of the velocities; to produce the same *useful* effect (the same useful effect, net weight), in the proportion of 3·11 to 1, or nearly as the cubes of the velocities.

This is the definitive result which Mr. Parkes has attained, and the help of which seems to him to render it needless henceforward to seek to determine either the friction of the wagons, or that of the engines, or the resistance of the air, or any thing in fact that may influence the effects produced; researches which appear to him to offer insurmountable difficulties. Possessed of the *wholesale* result of Mr. Parkes, nothing more will be needed. Does any one wish, for instance, to know what load a given engine will draw at 25 miles per hour, on a given inclination? to know what velocity it will assume with a load of 60 tons? to know what is the maximum of useful effect that it is capable of producing? to know what proportions must be given to it, in order to obtain desired effects? Why, having recourse to Mr. Parkes's result, the solution of all these questions is self-evident!

It is evident, on the contrary, that Mr. Parkes's result, even were it exact instead of being founded on erroneous calculation, could lead to but one thing, namely, to find the useful effect produced by an engine at the velocity of 30 miles per hour, when the same effect, in quite similar circumstances, is known at the velocity of 20 miles. But even then, making use of so rough an approximation, in which all is thrown in the lump: friction of the wagons, friction of the engine, resistance of the air, resistance owing to the blast-pipe, &c., the result could never be depended on. Assuredly, calculations like these do not tend to the progress of science; they would rather lead it back to its first rudiments. For this reason we persist in our belief that the only means of calculating locomotive engines, is to endeavour to determine, as exactly as possible, each of the resistances which oppose their motion, and by taking an account of the value of those forces in the calculation, we may then in every case attain a valuation really founded in principle, of the effects of every kind that are to be expected from them.

MR. RANKIN'S WOOD PAVEMENT.

(Abridged from the Polytechnic Journal.)

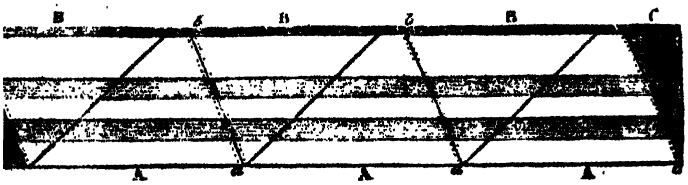
THIS new wood pavement is the invention of Mr. Rankin, and manufactured by Messrs. Esdailes and Margrave at their City saw-mills. We will first proceed to describe the process of its manufacture from the beginning. A square-sided piece of timber, of a proper length, is provided, each side being four inches across. By the application of the steam machinery at the saw-mills, two equilateral *grooves* are rapidly cut along the whole length of the piece. As soon as this operation is performed, the piece is turned completely over, and on the side immediately opposite to that previously grooved, two *tongues* are cut, in like manner, along its whole length.

The length of timber, thus prepared, will have two sides opposite o each other with plain surfaces, one of the remaining sides *grooved*, and the other *tongued;* and in this state it is ready to to be cut into blocks, to be laid down as street pavement.

Simple as this grooving and tonguing may appear to be, they constitute, in fact, a principal part of the merit of the invention. The fundamental principles of geometry have been strictly attended to in their construction, and the result is consonant with an adherence to scientific laws. The tongues of one piece of timber fit into the grooves of another; and when two pieces are thus united, the are not *flush* with each other, but the side of the second piece projects beyond the side of the first to which it is fastened, exactly half its own width. If a third length were attached to the second, in the same way that the second was to the first, the edge of this third length would again project beyond that of the second, half its width, and the same effect would be produced with any number of pieces.

The lengths, first prepared in the way described, will then have to be cut into blocks. In order to facilitate information on this part of the plan, we here introduce a diagram.

Fig. 1.



It will be observed there are two shaded parts, C and D, one at each end of the length. These are cut to waste; but the amount of loss is so small as hardly to be worth consideration in any estimate of prime cost. With this trifling exception, the whole of each piece, no matter how long it may be, is brought into use. The dotted lines, which intersect the length, indicate the direction of the saw when it is converted into blocks. A A A are base-blocks, and B B B the key-blocks. Let us, for the sake of an example, suppose that one length is cut into six blocks. Of these, three are intended to be laid upon the ground with their bases downward, and the other three to form the surface of the pavement by reversing this position, and placing their bases upward; and this is the only distinction between the blocks of which Mr. Rankin's pavement is composed. The lower blocks are called base-blocks, and these support the others; the upper blocks are called key-blocks, and these firmly interlock the under blocks and themselves together. The annexed drawing, fig. 2, represents the *grooved* side of a base-block, *a* and *b* being the grooves; and the engraving opposite fig. 3, presents the *tongued* side of the same base-block, *a* and B A being the tongues. The two similar sides of the key-block are also exhibited in the accompanying diagrams; *a* and *b* in fig. 4, representing the grooves, and *a* in fig. 5 the *tongue*. Such is the shape of the blocks of this most ingenious pavement; and begging our readers to bear in mind that there are but two sets, upper and lower, and that the individual parts of every block of each set are geometrically alike, we proceed to the proof of its advantages, with the promise of which we started.

Fig. 2.

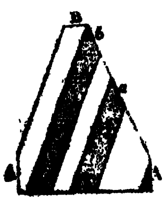


Fig. 3.

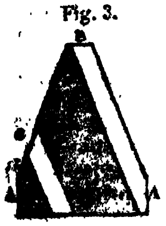

Fig. 4.

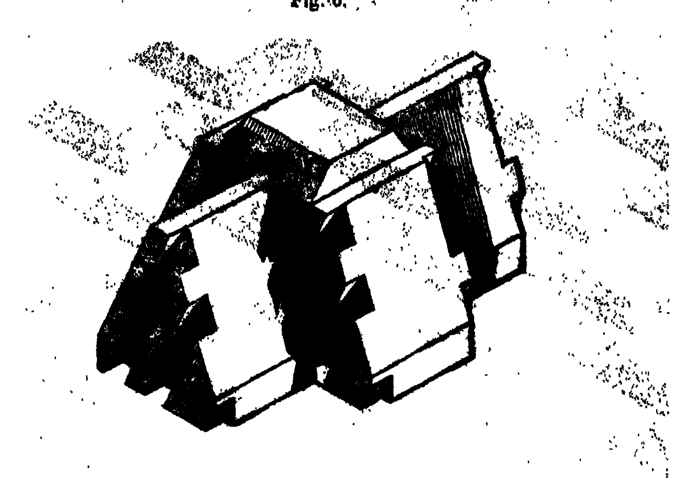
Fig. 5.

As "UNCHANGEABLENESS OF POSITION" is a primary and most important quality of this pavement, we will first explain how this is secured. Fig. 6 is a representation of five blocks locked together. It will be noted that four of these are base-blocks, and but one a surface block. If examined in detail, it will also be found that the key or surface block is supported by the others, and by all equally; and that no surface pressure can separate them laterally, or drive them asunder; so that any weight applied at the surface, is distributed over a base nearly four times its area; but these four base-blocks likewise respectively lock in with four other different series of the same kind, and so on continuously from side to side of the street, where they rest on the kerbs, and longitudinally from end to end of the pavement; and thus

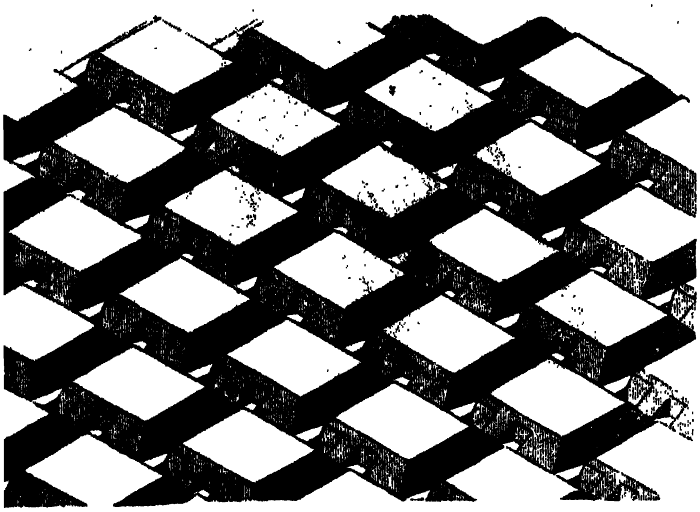
Fig. 6.



the weight applied to an individual surface block is not confined to the four base-blocks, its immediate supporters, but is transmitted throughout the whole structure, and no one part can yield to the superincumbent pressure, without causing a general deflection from kerb to kerb; and as this is manifestly impossible, except to a small amount, it must be granted, that the base of the pavement can never be affected, or dislocated, by any traffic whatsoever: no inequality of surface, from the sinking or depression of individual blocks, can consequently arise, until the surface blocks themselves are fairly worn out, a result which is assuredly much more remote in wood than the public are yet prepared to believe. The construction of this pavement, therefore, as regards uniform stability of base, places it beyond all comparison with any stone paving now in use, because it includes the principle of the arch, the kerbs representing the abutting piers, and the upper or surface blocks the key-stones; and the greater the weight, the more solid does the structure become by the tightening process of the wedge-shaped key-blocks, with their grooves and tongues. If our readers will again examine figures 1 and 2, they will observe that the angular terminations on two opposite sides of the base of every substratum block (A A) are chamfered or squared; and if, furthermore, they will suppose a row of these blocks to be placed on the ground between two piers, or abutments, with their chamfered edges together, and the upper blocks afterwards introduced in their proper place, it will at once be evident that no sinking can take place without complete destruction of the parts. In truth, by this arrangement of shape, unchangeableness of position is absolutely obtained.

But, after all, the most important consideration in the adoption of wood as a substitute for stone in the street-paving of the Metropolis, will ever be the providing an effectual REMEDY AGAINST SLIPPERINESS. No pavement of wood, that does not offer a firm foothold for the horse in all states of weather, will ever become generally adopted in London. In every situation, whether in continuous motion, in backing, in being abruptly pulled up or suddenly started, the horse must be able to maintain his feet in precisely the same place in which he places them down, otherwise wood pavement will not have realised the grand advantage of which it is susceptible. That nothing of the kind has been hitherto accomplished, needs but a five minutes' examination of any public street paved with wood immediately after and during the existence of a passing shower. The plunging and sliding about of the animals are then awful. If an omnibus going at the usual speed were suddenly required to be stopped to take up a passenger, its momentum would force the horses along the pavement several yards, in spite of all their efforts to prevent it. In starting too, their feet rapidly slip from under them for several moments before they can succeed in moving the vehicle. Frequently they fall down and are injured, and the greatest precautions are necessary under such circumstances to prevent accidents. These things happen because there is no foothold for the horse in damp weather upon any of the wood pavements hitherto introduced. We can testify, of our own knowledge, that the reverse of this is the fact in the case of Mr. Rankin's pavement. Indeed, it speaks for itself; no argument is required to prove that the foot of a horse cannot slip over its surface. At the same time it offers no resistance to the uninterrupted progress of the wheel, and therefore a remedy against slipperiness is not obtained by any sacrifice of facility of traction. A general character of the paving may be gleaned from the annexed engraving.

Fig. 7.



Here, then, as the licencees fairly remark, is a pavement, removing at once the great and hitherto insurmountable evil attending the use of wood, the insecurity of the horse's foothold; and offering a facility of removal equal to the present stone paving, and an evenness of surface, and combination of construction, together with an absence of noise and increase of cleanliness, which wood alone can give.

We have felt great pleasure in thus calling the attention of the public to the invention of Mr. Rankin, because we know it to be very ingenious, and believe it to be, for all seasons, by far the best wood pavement hitherto made public. The government ought to allow an experiment upon an extended scale to be made with it duty free, for the question of wood pavement is one of metropolitan, if not of national, convenience.

PROFESSOR FREUND, DANISH SCULPTOR.

If not in the fine arts generally, the north of Europe has distinguished itself in sculpture—that one of them, on which the fame of Greece now chiefly rests, and which more especially demands a critical study of beautiful forms and proportions. The eminent and excellent sculptors Sweden and Denmark—and we may add Russia—have given birth to, sufficiently vindicate their pretensions and character in that branch of art. The names of Martos (+1835) and Boris Orlovsky (+1837), of Sergell, Bystrom, and Fogelberg (belonging to Russia and Sweden), may be said to be European ones, while that of the great Danish master almost dims that of Canova himself. Neither is it of her Thorwaldsen alone that Denmark has cause to be proud, since she can boast of having given to the world another highly gifted sculptor in Hermann Freund, who died at Copenhagen in July 1840.

Of this last-mentioned artist we are not as yet prepared to give any biographical sketch, nor even to enumerate his principal works. We are enabled, however, to state a few particulars relative to some of his subjects from ancient northern mythology, which had been a favourite study with him, and of whose imagery and traditions he sought to avail himself for plastic and sculpture, in like manner as his countryman Oehlenschläger has done for poetry and the drama. It was here that he displayed poetical conception, a noble simplicity, a characteristic yet graceful severity, free from aught like mannerism, and from those mere conventionalities upon which so much stress seems to have been laid by most modern sculptors, to the exclusion of either originality or feeling. Among the works of the class above referred to, is a bas-relief representing the three Nornas or northern Fates, who are consulted by Mimer, Baldur, and the Valkyrias, in consequence of Iduna, the goddess of youth, having been carried off by the evil spirit Loke, and thereby both gods and mortals subjected to the infirmities of age and decay. In this dilemma Baldur, the Apollo of the Scandinavians, solicits the counsel of Mimer, the god of wisdom, and he, being unable to assist by his advice, they both proceed to solicit that of the Norns. These last form the centre group in the composition, and represent Veranda, she who presides over the *present*, Ur, who presides over the *past*, and is here seen recording its events upon a tablet; and Skulda, or the *future*, with her finger upon her lips. To the right of these figures are those of Mimer and Baldur, the former with a long beard and arrayed in a bear's skin, the other a beautiful youth, vying in form with his classical prototype. To the left of the centre group are the three Valkyrias (whose office it was to tend upon the souls of the blest in Valhalla, the Scandinavian Elysium), who are here represented as attired in long under garments, and with wings growing from their temples.

Among Freund's single figures and statues are many representing personages belonging to the same mythological system: viz. Odin, Thor, Freya, Iduna, Bragur & Loke. The first-mentioned of these is seated on a throne, and wears a diadem inscribed with Runic characters. He is the Scadinavian Zeus, and like the Grecian one, is distinguished by majesty of appearance, but his features are more aged, his form less expressive of strength; for though superior in power to the rest of the deities, Odin was supposed to be himself under the control of Fate—an arbiter more awful and tremendous than even the sovereign of the gods. His attributes are two ravens, seated on the arms of the throne, which were the messengers commissioned to bear his orders to gods and mortals—and two wolves couched at his feet.

Thor or the Thunder-god, is a standing figure, with his right foot advanced forwards, and looking earnestly on one side. He is here supposed to have just hurled forth his lightning, and to be striking a thunder-peal with his hammer. This figure—which is somewhat between that of a Jupiter and a Hercules—is quite naked with the exception of a wolf's skin, hanging upon one arm, and reaching to the ground. Beside him is a coat of mail, which serves to support and balance the statue. In a second figure he is somewhat differently represented—in a more composed attitude, with his hammer in his right, resting upon his armour, and a thunderbolt in his left.

In the group of Freya, the goddess fabled to preside over sexual passion, that figure is represented veiled, resting her chin on her right hand, and holding a wreath of flowers. On one side of her is Siofne (under whom was typified the first emotion of love), endeavouring to draw aside her veil and behold her countenance; while on the other is Hnos, or Enjoyment, with her left arm around her mother Freya's neck. Both Siofne and Hnos are naked figures. So far the allegory seems well conceived, but there is one circumstance which, though it may be significant enough as a symbol, is far more associated with the ludicrous, than with either the sentimental or poetical, according to modern ideas; for instead of turtle-doves, the northern Venus has at her feet—two cats! as images of the potent influence of *la belle passion!*

Iduna, the Scandinavian Hebe, is represented by a graceful youthful figure, holding in her left hand a patera filled with apples, and in her right a cup of mead. Her luxuriant tresses fall from beneath a long pointed cap, similar to that still worn by the maidens of Iceland, which hangs down behind, where it terminates in a tassel.

Bragur, her consort, and the Scandinavian deity of poetry and minstrelsy, and whose office it is to recreate the indwellers of Valhalla with his songs, is shown in the act of playing upon his harp, which is attached to a riband that crosses his shoulders.

The evil malicious spirit, Loke, is characteristically described—under a shape speakingly expressive of the disposition attributed to him. There is something stealthy in his very attitude, as he creeps along resting his chin upon his left hand, while brooding upon mischief. His other claw-shaped hand is partly concealed beneath his mantle, as are likewise his long and ugly ears, and his bat-wings.

However admirable may be the talent manifested in those productions, it is with us a question whether it might not have been more advantageously employed. If heathen mythology is now worn out, it it does not address itself to our sympathies, especially when served up—as it necessarily must be in modern sculpture, at second-hand that of Scandinavia has to contend with the additional disadvantage of being less known, consequently less intelligible. All attempts to revive it, to bring it again into vogue, either in poetry or the graphic and plastic arts have proved comparative failures. Did the fame of Gray rest chiefly upon his productions of that class, it would be much less than what it actually is; or rather, he would share the fate of Sayers, whose northern poetry has been descanted upon and praised by critics, to be forgotten—supposing it ever to have been regarded—by the public.

A new Paving.—M. Polonceau, the engineer of Paris, proposes a new mode of paving for Paris, consisting of artificial stones made of clay, sand, and pulverized charcoal. This mixture stood heat well, and became vitrified; it also dried without cracking. The stones were made in an hexagonal form and could be put down or taken up one by one. Government had given leave for an experiment to be made of this system in one of the streets of the capital.

COMPETITION DESIGNS.

(Benevolent Institution for the Relief of Aged and Infirm Journeyman Tailors.)

The mal-administration of competitions for designs becoming every day more apparent, the indignities and imposition practised upon architects who are foolish enough to yield to importunity and submit the result of their labours to the decision of men not merely unfitted for the task, but in most cases *prepared* to decide in a certain manner even before the reception of the drawings, becoming additionally glaring, it surely only needs that some few more home-cases should be brought forcibly before the public eye to induce the entire abandonment of the present scandalous system, and to enforce from committees an honest decision and something like consideration for the time and talents of the professional men applied to. With this view we proceed to lay before our readers the particulars of a recent competition which have come to our knowledge in the hope that the statement may aid in rousing public indignation against such proceedings: furthermore, we have a latent hope that by putting the whole matter fairly before the parties interested they may be led, as it is not yet too late, to retrace their steps.

Some few months ago the Committee of the Institution named at the head of this article, requiring designs for an asylum which they propose to erect in the Hampstead Road, invited a limited number of architects to forward drawings, namely Messrs. Lee and Duesbury, Mr. Jones, Mr. Vulliamy, Mr. Thomas Meyer, Messrs. Winterbottom and Sands, Mr. George Godwin, and Mr. E. H. Browne.

It being understood that one of the competitors, namely Mr. Meyer, was brother of a member of the Committee and had already sent in a design, some of the other architects inquired pointedly whether or not this gentleman was to be in any degree considered more than the rest, and were informed by various members of the committee that the best design would positively be accepted whether made by Mr. A. or Mr. B. Designs were accordingly sent in by all the gentlemen we have named. A building committee was appointed by the general committee to examine the drawings, and recommend for adoption that which they considered the best. They accordingly met various times, gave a long consideration to the matter, and ultimately selected Mr. Godwin's design as the fittest for their purpose; a written report to this effect was drawn up and the matter was talked of out of doors as a thing settled. Several weeks having elapsed after this had reached Mr. Godwin's ears accidentally, without his receiving any special communication, he applied to know how the competition had terminated, and the following letter was shortly afterwards sent to him:

Benevolent Institution, &c.
32, *Sackville Street,*
14*th July*, 1841.

Sir—I beg leave to inform you that, by a decision of the Board of Directors, their choice of an architect has fallen on Mr. Meyer.

I am, Sir,
Your obedient servant,
George Godwin, Jun., Esq. T. P. Davidson, Sec.

The gentleman to whom this was addressed accordingly called the next day to fetch away his drawings, and being shown into the room of meeting, saw there five of the seven sets of designs, including those selected as the best. In consequence of this examination he immediately addressed a letter to the Board, which, as it puts the whole matter in the fairest point of view possible we here annex

To the President and Directors of the Institution for the relief of infirm Journeyman Tailors.

Brompton, July 17, 1841.

Gentlemen—I have the honour to acknowledge a note from your Secretary, stating "that the choice of an architect has fallen on Mr. Meyer."

Some time previously I was told, in three different quarters, that *my* plans had been selected by the Committee as the most approved, and I felt, therefore, a little disappointed on receiving official intimation to the contrary; still, considering that I must have been misinformed, I was of course quite disposed to bow to the decision in silence, and to believe that a better plan than my own had been chosen.

Applying, however, a few days back in Sackville Street to regain the drawings, I there saw the various designs of the other competitors. Amongst them were those of the preferred candidate, and an examination of these led me to the conviction, that such a decision had not been come to as those architects who had given their time and attention to the subject at the request of the Board, had every right to expect. I make this remark with the greatest deference to every member of the Board, for many of whom personally I have great respect.

Far be it from me to deny that the Board had right to appoint any architect they pleased; what I would very deferentially submit is, that having induced six or seven architects to make plans for the proposed asylum, at an expense of both time and money, in the full persuasion that the author of the best design would be appointed to execute the building, the Board were bound to make that selection solely on the *ground of superiority*, and without reference to the name of the author of the plan.

That such has not been the case, adverting solely to the designs submitted, and without the slightest intention of disparaging Mr. Meyer's fitness for the task, I venture without hesitation to assert.

Apart from private grounds (and even in this respect, as my plan was selected by the Building Committee after due consideration, as the best adapted to your purpose, I am, perhaps, authorised to address you,) I am induced to this step by strong public motives—by that desire to obtain a just administration of competitions for designs which is felt at this time by all those who wish the prosperity of the arts in England.

On this ground then, gentlemen, I appeal to your sense of justice, and the desire which, I will venture to believe, you all have to maintain the good opinion of the world, to give this matter re-consideration.

I hope sincerely that you will not deem any thing I have said disrespectful in the slightest degree, and that you will permit me to subscribe myself, gentlemen,

(Waiting your decision),
Your humble servant,
Geo. Godwin, Jun., Architect.

The result of this letter was that the Board, at their next meeting, refused to confirm the appointment of Mr. Meyer, and it was proposed that the whole of the designs should be referred back to the decision of one or more architects. A subsequent meeting, however, influenced in a manner one would hardly venture to hint at, overturned this intention and confirmed the original appointment. Here the matter stands. We have seen the various plans, and without stopping to inquire whether Mr. Godwin's plan is the best (a point we don't in the least care for), we have no hesitation in saying that not merely is the selected design *not* the best, but that it is perhaps the least entitled of any one of the seven to claim for its author the appointment. If the Board desired to employ Mr. Meyer, why did they not do so in the first instance? No one would have questioned his fitness, or their right to appoint. But having given seven gentlemen the trouble, and led them into the expence, by special invitation, of preparing designs, we assert that the Board were bound, by every feeling of honesty, to appoint the author of the best plan, without the slightest reference to his name or his connexion with the society. We hope even now it is not too late for redress.

COMPETITION.

Sir—If your readers will refer to the Athenæum for the last month, they will find an account of a highly entertaining squabble arising out of the competition for a new church in the parish of Paddington.

When this competition was announced, I applied for the particulars, and subsequently for further information on a few points which did not appear to my humble comprehension to be quite explained in the instructions. Without troubling you with the whole list, I will mention one question, viz. How many of the prescribed sittings were to be in pews, and how many in free seats? to which I took the liberty to add the further inquiries, whether any member of the vestry would be permitted to compete, and to whose judgment the designs were to be submitted. To which answer was made, to the first question, that many architects had applied for the like information, but that the instructions already given were considered sufficient—to the second, that no member of the vestry *could* have an interest in any parish work—and to the third, that it was calculated to give great offence! and that it was quite enough for the architect to know that the parties concerned were "all honourable men."

Of course all applicants were obliged to be content with the same answers, for, *of course*, nobody gave, or profited by, private information—nobody ever does. I submit, therefore, that any one who competed after receiving such answers, got what he deserved, whatever he may have or may think he has to complain of, and I trust that none of the profession who lend themselves to the system of scrambling for jobs in the dark, will ever be better treated.

I am, Sir,
26th August. Your obedient servant,
T. J.

ON RAILWAY CARRIAGE WHEELS.

Sir—In your number for June last, there is a paper, page 197, professing to contain accounts of improvements in Railway Carriage Wheels.

The writer's first two heads of method contain two different modes of constructing the axle of a pair of wheels, to allow these to turn independently. One would infer from his manner of stating the modes, that they should be united in one pair. They evidently cannot. At all events, he implies that, on either plan, the independent rolling of the wheels, together, I suppose, with the additional flanges, would entirely prevent the engines being thrown off the line by an obstacle. Now the *independence* of their rates of motion cannot facilitate the prevention of such an accident.

In his third head he tells us that his wheels should be of cast iron, preferably to malleable iron. But why this preference? It is universally agreed that malleable iron is superior to cast iron for all wheels of the kind now in use. Why are the writer's wheels to be an exception? Is it on account of spreading? The writer himself says that malleable iron wheels spread out only on the bare side. And, therefore, now that they are to be flanged on both sides, the spread will be checked, therefore let us yet use malleable iron. There is no other new circumstance requiring this change of metal. The jolts, strains, and every thing else will be the same. Again, therefore, let us yet use malleable iron. His preference for cast iron is of a kind with the dislike of Dr. Pell versified in the immortal quartet so often quoted. Again, he says that the wheels as they are double flanged will not require to be so strong as at present, because side jolts will be divided between the opposite wheels. The consummation of lateral strains and jolts would be both wheels rising on the rails, which case, therefore, we must consider in judging of the required strength. Admitting the writer's assumption that both wheels share the strain equally, (which however cannot always be, as in cases of variation of gauge, which fact itself is an argument against his conclusion), it is clear, as Telford has it, that the engine on being raised, is elevated on both rails through the depth of flanges, and that therefore its centre of gravity also rises through the mean depth of flanges. Now with the single-flange wheels the engine would be raised only on one side, through the depth of flange, and therefore its centre of gravity rises through only one half this depth. It is clear again, then, that double flanged wheels would have as tight work each as the single flange wheel, and therefore *would* require to be as strong. What right has he to deny this, who never proved the contrary? He again says that the face of the wheels ought to be in outline a circular segment instead of conical. Now the face of a wheel, as he views it, is not conical; it is a straight line inclined to the axis. He proceeds to mention by wholesale the great saving in his plan. Particularly, he says, no attention will be required in laying the rails to an angle in straight parts. What although, there will be the same attention altogether in laying them horizontally? At all events, he allows that the angular position is required at curves. But under the fifth head, he says that railways are all curves together; therefore he must conclude against himself that the saving in straight parts is just nothing, since he supposes there to be no straight parts at all.

Again, he says that the inclination of the rails the same way on curves instead of towards each other, as now set, will enable gravity to act more forcibly. This can be only on the ground that the comparative virtual velocity in the direction of gravity is greater in the first case than in the other. The writer has evidently not troubled himself as to the truth of this gratuitous statement. It would be easy to prove that the centre of gravity moves through equal depths for the same horizontal movement, in both cases. And therefore is he entirely wrong.

Again, he says that the inclination of the rails to one another in present plans causes great friction on the journals. How so? The pressure on the journals must be the same. Nor is there any twisting or other adverse action of the kind. In fact, the only sources of friction by this cause would be at the contact of wheels and rails, owing to the wedge-like action of the conical wheels, which is utterly insignificant. Again, each wheel cannot possibly press the other against the rail, for their action is equal and opposite, and therefore nothing.

In his fourth head he has asserted all, proved nothing. How did he know the exact saving of power he mentions? It is evident that his improvement was never in operation. What right had he then, when he knows nothing about it, to pronounce so decisively as he has done, and that not only in this paragraph, but throughout the whole paper.

His last notable and most ridiculous statement is set down in the fifth head. He tells us that railway curves do all differ in intensity, and they must therefore be of various radii. But this evidently requires wheels of various diameters to suit them, and to produce that sweetly-gliding motion which he loves. This exigence is beautifully provided for in conical wheels. Now, he proposes to set his engine running upon the flanges of the wheels forsooth when they enter upon curves. By this exceedingly quack plan, the wheels are evidently adapted to only one kind of curve, and would therefore, on any other curve, grub up the rails most sweetly indeed.

I am, your's, respectfully,

D. C.

Glasgow, July 9, 1841.

QUESTIONS FOR THE OPINION OF THE EDITOR.

Sir—I shall feel obliged if you will inform me if I could sustain a charge in a court of law under the following circumstances. In the early part of the year I was applied to, amongst other tradesmen in the parish, to tender for certain alterations and additions required to a building, in the erection of schools, and in due course I was informed that my tender was accepted, and that a delay of a week would most likely take place, but from that time to this, a period of six months and upwards, I heard nothing of the matter until a day or two since, when I received a letter (certainly a polite letter), stating circumstances prevented the design from being carried into effect, and that they were sorry I could not have an opportunity of carrying my contract into effect.

Do you not think, Sir, I should be fully justified in charging two per cent on the amount of my tender, as some judgment was necessary and much time taken up in making the estimate.

I am, Sir,
Your obedient servant,
Aug. 9. T. O. M.

In all cases when our opinion is required, we should be furnished with full particulars; for instance, in the above case, a copy of the advertisement should have been forwarded. Taking for granted that there is nothing very special in the wording of the advertisement, and that there was nothing personally objectionable to the tradesman making the tender as to his general way of doing business in point of construction, or for want of pecuniary means to fulfil his contract, we are then of opinion that a claim could be legally substantiated against the parties advertising.

We have some recollection of a case being tried about six months since, either in the Sheriffs' or Secondaries' Court in London, of a builder suing a person for the trifling sum of about 3*l*. for his loss of time in making an estimate of some works; after receiving the tender, the defendant declined employing the plaintiff, without showing any reasonable excuse; in this case the plaintiff recovered the sum sued for. Our impression is that there are other cases which might be cited; probably, before our next number appears, some of our readers will be able to furnish us with some information regarding this question, which is one of very great importance, not only to the builder, but also to the profession.—Editor.

Sir—I thank you for your reply respecting the legal arrangement of chimney flues, and from which I gather that the termination at top, if of different materials from the stack, may be of any size that one pleases; but suppose I choose to have nothing resembling a chimney-pot, is it your opinion that the law will forbid such a contraction for the last two or three feet of the brick or stone, as is now effected by the addition of the cement or pottery abominations?

I am, Sir,
Aug. 10. Your obedient servant,
A subscriber.

If the chimney be built as our correspondent suggests, it will be necessary, in our opinion, to construct it with an aperture not less than 14 in. by 9 or 12 inches diameter, agreeably to the Act. We hope that the legislature will see the necessity for altering the clause in the act before it comes into operation; the Architects' Institute or Society should interfere and obtain a repeal or modification of the objectionable clause before the act comes into operation.—Editor.

Sir—I have lately had an opportunity of seeing the Illustrations of Ancient Halls by Nash. Now it struck me at the time, that though they were certainly very pleasing to the eye, how much more *useful*, simple but correct outline elevations and plans would have been to the architect and others, as it would be the means not only of preserving a true delineation of the subject, but would also be the means of furnishing numerous data in erecting similar edifices, which I know to be useful to all. Now as many very beautiful specimens still exist in this part of the country, I have it in contemplation to bring out a work of this kind. The only question is, whether architects will patronize it as they ought to do, as I am sure plans, elevations, &c., of such buildings must be very acceptable to them. If you will be kind enough to give your opinion in your next number, I shall feel greatly obliged.

A Subscriber.

Such a work as our correspondent describes has already been commenced, but not proceeded with. We think a work got up at a moderate price, suitable for the architect, might stand a chance of meeting with support, but we are afraid to recommend the publishing of it, as it is very doubtful if our correspondent would be remunerated for his labour.—EDITOR.

MOVEABLE FURNACE BARS.

SIR—With your permission I beg to make the following remark respecting an article which appeared in your valuable Journal of last July, under the head of "New Inventions and Improvements." The article in question is one which I suppose to be an extract from the specification of Mr. C. W. Williams's patent improvements in furnaces and boilers.

If there be any credit due to the discovery of the method therein described, for producing the continual up-and-down movements in the grate bars, that credit is most certainly due to the late Mr. Mathew Murray of Leeds, who had the furnace of an eight horse steam engine, so constructed as to keep the grate bars continually in motion, by means of small eccentrics formed on a horizontal shaft, which revolved beneath, and supported the ends of the grate bars next to the furnace bars. This was done with an intention to prevent the formation of clinkers, and to keep the fire perfectly clear; but, as the plan did not prove perfectly satisfactory to the inventors, the whole system was very shortly taken out, and replaced by that then most commonly adopted. It appears to me somewhat singular that this contrivance, though upwards of fourteen years old, should at length become the leading feature in a specification of patented improvements.

I am, Sir, with great respect,
Your humble servant,
FLORENTINE.

Holbeck, August 16, 1841.

REVIEWS.

A Series of Original Designs for Churches and Chapels in the Anglo-Norman, Early English, Decorative English, and Perpendicular Styles of Ecclesiastical Architecture, including also designs for Rectory Houses and Schools in the Domestic English and Tudor Styles. By FREDERICK J. FRANCIS, Architect. London: John Weale, 1841.

This forms the first part of a series of original designs, which are divided into four classes. 1. The Norman. 2. The Early English. 3. The Decorated English, and 4, the Perpendicular English. We do not think however from the specimens before us that Mr. Francis is so happy with his pencil as with his pen, neither are we of opinion that these designs are likely to induce the Church Building Commissioners to abandon their "Barn Church Architecture." We might instance several defects, for instance in design No. 1, we have the principal entrance opening direct into the body of the Church without any lobby, or second entrance; the same again in the side entrance of No. 2, nor do we admire the stunted steeples which have been introduced in designs Nos. 2 and 6, the pedimental parapet of No. 7. and the stepped parapet of No. 12 design, nor the square hood moulding over the pointed windows of the clere-story.

Description of a Series of Geological Models. By T. SOPWITH, M. Inst. C.E., F.R.S., &c. Newcastle: Blackwell.

As a Mineral Surveyor Mr. Sopwith has had excellent opportunities of acquiring practical geological information, and he has been no less successful in imparting it to the public. The models, which this work is intended to describe, illustrate the nature of stratification, valleys of denudation, succession of seams in the Newcastle Coal Field, the effects produced by faults or dislocations of the strata, intersection of mineral veins, &c. These models are very ingenious and useful, and the work before us besides being a necessary companion to them, is of great interest on its own individual account. The illustrations being drawn from actual inspection, and greatly to the merits of the work, which abounds in practical instruction on mining geology.

PARLIAMENTARY PROSPECTS OF THE ENGINEERING INTEREST.

A change in the administration of the country being imminent, it is the bounden duty of the engineers, both civil and mechanical, to profit by the present state of affairs to obtain redress for their numerous grievances. No time can be more appropriate than the opening of a new parliament to canvass for a change in the Standing Orders of the House of Commons, and the formation of a ministry is a good opportunity for securing a sound system of government policy. When we consider the vastness of the interests involved, and the extent of influence at the command of the engineers, we entertain no doubt of a relief from the oppressions by which they have hitherto been afflicted. It may not be in the power of the engineers to meet together at this season and act in concert, but it is at least open to them to exert themselves individually in influencing the members for their several towns and districts, who may be called on to co-operate in a cause, which is nonpolitical, and of the greatest importance to the industrial interests of the country. It is perhaps fortunate that Sir Robert Peel has hitherto shown himself favourable to our interests, and we think that after the formation of a new ministry under his guidance, no time should be lost in ascertaining by a deputation of men of all parties the course he intends to take upon the momentous questions of the Standing Orders, Railways, Steam Navigation and the Irish Railways, so that the engineers might be able to take their measures accordingly.

MR. JOHN SCOTT RUSSELL'S TREATISE ON STEAM NAVIGATION.

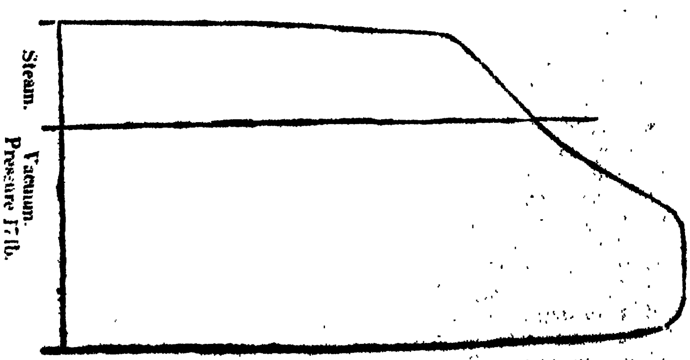
SIR—In a late Treatise on Steam Navigation, by John Scott Russell, I observed a statement regarding a steamer lately constructed on the wave-line principle, which ran thus, page 304, "the next and last vessel is the Flambeau, built in 1840, on the wave principle, by Mr. Duncan of Greenock, with the co-operation of the present writer. This vessel with the smallest proportion of power to tonnage, and with the smallest supply of steam, is nevertheless by far the swiftest vessel on the Clyde." Now I think "the present writer" ought not (although the vessel was constructed on the wave principle), to have allowed himself to go beyond the bounds of truth, I mean in the three last sentences. 1st. "She has the smallest proportion of power to tonnage." This is certainly doubtful, as you will see by the following indicator diagram, taken when at the speed of 24 strokes, (now she has many times made 27 strokes per minute), making 138 horse power; not as Mr. Russell has supposed, or rather wishes to make the world believe to be 70 only. Now taking her at 280 tons measurement, we have $\frac{280}{138} = 2$ tons per horse power. If that is the smallest, pray what may be the largest,—and yet with all this she was not by far the swiftest.

2nd. "With the smallest supply of steam." I understand the first boiler was not capable of supplying steam to the engine the whole length of stroke, so that they expanded one-third or 20 inches, as was intended, and pressed a little higher to compensate; yet so much was Mr. Russell disappointed with the speed of the vessel, that he attributed the deficiency of speed to the deficiency of steam, and accordingly with his usual tact, got the proprietors prevailed upon to put in another boiler that should follow up the steam, which they accordingly did, and pressed at about 6 or 7 lb.; the result was her speed diminished to Mr. Russell's mortification, and time, labour, and money lost to the proprietors.

3rd. "Is nevertheless the swiftest on the Clyde." With her first boilers I grant she was the swiftest last season, only when she made the 27 strokes, but this season she is not classed among the swiftest. Now this is a statement of facts, as Mr. Russell knows very well.

Cylinder 48 in. diam.
Stroke 5 feet.

$$\frac{48^2 \times \cdot 7854 \times 14 \times 240}{44000} = 138 \text{ horse power.}$$



Mean pressure 14 lb.

Your insertion of the above in your useful Journal, will oblige,
Your obedient servant,
H.

August 14, 1841.

REMARKS ON RAILWAYS REPORT AND EVIDENCE.—1841.

SIR—The report of the "Select Committee appointed to consider whether it is desirable for the public safety to vest a discretionary power of issuing Regulations for the prevention of Accidents upon Railways, in the Board of Trade; and if so, under what conditions and limitations;" together with the evidence upon which such report has been founded, has fallen under my notice, and with the view of adding my experience and reflections to the general fund of information upon railways, I request the favour that you will lay the following observations before the public at your earliest opportunity.

I am an engineer of 18 years' experience in my profession, and for the last 6 years have been intimately connected with railways, principally in endeavouring to introduce into the system various contrivances by which the public safety will be increased.

It has occurred to me as a matter of great regret that the Committee was not assisted, during its deliberation, by a practical engineer fully versed in the various railway details which were brought under its consideration, a practice which is quite usual in the Admiralty Courts, by which the testimony of the various witnesses would have been checked; for it is just evident, had such been the case, the extraordinary opinions and assertions advanced by some of them, would never have been broached, as it is clear, when the questions of the Committee were directed in such a way as to convict a witness from his own testimony, the party never failed to take refuge behind some technical details, into the peculiarities of which the Committee could not follow. A striking instance of this occurs in (Question 567) Mr. Brunel's evidence, who states as the probable cause of accident, "that perhaps a pair of wheels upon a train is slightly out of gauge, being too narrow, that in passing some guard-rail they get strained, and that when they come to a part of the line which is rather wide in gauge, they get off, and the train is delayed." Now every technical man of experience knows that if a pair of wheels be out of gauge, the fault is in the construction of the spindle, for if every spindle is made with a collar or shoulder, so that the back of the boss of the wheel butts against it, a method I invariably practice, if the wheel run round upon its axle it could never get out of gauge, so that *a regulation* providing that every axle should be made with shoulders would be a very wise and proper regulation, and would apply to all railways whatever.

In another part of his evidence Mr. Brunel states that amongst other causes of accident, "a policeman immediately runs up, and stands right in the way of the tail-lamp of the train, and the next train runs into it. Now the majority of persons would say, that if the policeman had done his duty, and showed a red light, and if the engine-man had seen the red light, there would have been no accident." If the policeman, in the case of accident, received positive instructions to run back 500 yards and hold his red light, so that the engineer of the succeeding train should not fail seeing it, this precaution, one which I have invariably insisted upon, under whatever case or form of accident, is, and would always be, an efficacious and proper *regulation*.

Mr. Brunel states, amongst other minor improvements, it would be better for the wheel not to touch the guard-rail: a man who knew any thing of a railway would then have inquired the use of the guard-rail, because, this being placed purposely to guard the wheel from the point on the opposite rail, if the wheel was not governed by it, it is useless—and there is no secondary use for it, as Mr. Brunel endeavours to make it appear in Ques. 604, and so far as the use and principle of the guard-rails go, it is the same in all cases *on all railways*.

There is another observation in the same answer, so palpably in the teeth of experience, that I cannot fail here to notice it, and that is the denial on the part of Mr. Brunel that railway improvements can be made by any parties excepting by those connected with railways. It would have been a proper question following this assertion, if Mr. Brunel had been asked whether his own father was originally a block maker, and whether the fact of his not being so would have been a proper reason for Sir Jeremy Bentham declining the encouragement due to Sir I. Brunel's very admirable machinery for making blocks by machinery—or whether the illustrious Watt was an engine driver, or before his improvements in steam engines he was actually accustomed to the management of steam engines—or whether Arkwright was a cotton spinner—or Mr. James, the father of railways, previously to his conception of railway extension, was intimately and exclusively connected with railway matters—and lastly the inquiry might have been made, what improvements have been introduced, I will not say invented, by *railway* engineers since the formation of the Liverpool and Manchester Railway, and in what respect this last mentioned railway differs essentially from a colliery railway that had been formed half a century before it.

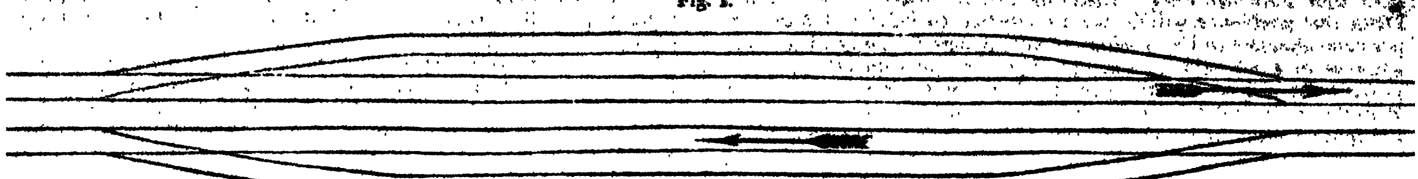
And whence does it arise that the improvement of railways, contrasts so essentially with the advances made by the great branches of trade, and manufactures, since their first introduction, but from the fact of the monopoly of the companies on the one hand, and the disinclination of railway engineers to introduce any contrivance which does not emanate from themselves, on the other; had a liberal spirit prevailed amongst engineers, and had they the judgment to select from the mass of crude suggestions offered to them, railways would have been by this time not only safe by contrast with stage coaches, but absolutely so, there is no reason why the system should not have been so formed as that, by no chance or design could an injury happen to passengers, and no one contrivance would conduce to this result more certainly and more directly than the adoption of the low carriage, upon the principle of those invented by myself, and in use upon the Greenwich Railway, and although Mr. Entwistle takes credit for the arrangements upon the Greenwich line, inasmuch as 6,800,000 passengers have been carried without the loss of life or limb to any one, he had not the candour to admit that this gratifying result is to be attributed mainly to the *construction of the carriages*, for the accidents from broken axles, &c., have been much greater upon the Greenwich line than upon any other in the country, and but for the low carriages, some most awful accidents would have resulted. I may here mention that the Board of Directors to which Mr. Entwistle belongs, have not only done their worst to disgust the public by the manner in which their carriages are kept, but they would have been long since abolished by the Directors but for the resistance made to that measure by the parties who are in the habit daily of using the line. This fact is one more in proof of the necessity of some supervising power to control the measures of railway managers.

The mode in which Mr. Brunel attacks the recommendation of Sir F. Smith that an engine should not be loaded beyond a certain amount, proves again the necessity that a technical judge should have been in communication with the Committee; in that case I can scarcely believe Mr. Brunel would have indulged in the same arguments. The power of a locomotive is resolvable into two elements, the quantity of water evaporated by it, and the gradients it passes over; therefore, instead of appealing to one of these elements, viz. the gradients, had Mr. Brunel included both, the proposition of Sir F. Smith would have proved a most reasonable one. Had Sir F. Smith's proposition been that the load behind an engine should bear a certain ratio with the area of the cylinders, multiplied by a certain constant, having a ratio with the average gradients of the line, it would have amounted to the very rule of every-day practice upon any railway whatever, and by making either of these ratios fully within the average working condition of an engine, he could have so defined his object as to have ensured the punctual observance of his rule by the railway companies, a rule to which no reasonable objection could be made.

The advantage resulting from *massing* the trains, by the average power being thus obtained from the engines connected together, is, in my opinion, a very questionable one: supposing a very heavy train has two engines a head, and that the last engine runs so *dry* as to be useless; supposing, likewise, that the train is at a considerable distance from a siding or watering place, or a station whence another engine can be obtained, the power of the engine in good order will be almost entirely absorbed in dragging the defective engine behind it, and thus, the entire load will be retarded, and perhaps dangerously so. Had each engine taken its own load, the defective engine with its load would have been alone delayed: and, talking of expense, it would have been much better economy that a disabled engine and a small load should have been left at the first siding out of Bristol, than that a good engine should be strained and worked violently, and a heavy train delayed a considerable time throughout its journey to London, deranging all the arrangements, and endangering the line throughout. As to the maximum velocity, that could be disposed of in the way before mentioned, for the word power is resolved into the same elements, whether it be employed for draught or flight.

Mr. Brunel states "that with the best assistance of professional men, and others whose whole time and peculiar capabilities are applied to the system, we find it difficult enough to make our regulations sufficiently general to apply even upon our own line, and that the great difficulty in drawing up any code of regulations always is, to make a good regulation which is sufficiently applicable in all cases even on our own line of railway." I will prove that this very desirable system of uniformity can be easily accomplished as regards stations, and that is, to form them in such way that neither trains nor passengers shall ever cross the line. Fig. 1 will explain this method, by which it will be perceived that sidings must be placed on both sides of the line, and the crossings in such way that a train enters and departs from the siding without *backing*, backing into a siding being unquestionably most gothic and unskilful, the only apology for it being

Fig. 1.



the incapacity of the engineer to construct a safe switch and point. The passengers will enter into the offices by a bridge over or under the railway, as the case may be; it will not be out of place here to remark upon the most injudicious and unscientific practice adopted upon the Great Western Railway, in common with many others, of laying all the crossings along the line in one direction, by which means it is indispensable to back the train across the line, and bring it consequently to a dead halt twice before it can pass upon the wrong line; the apology for this is, that the peculiar switches adopted require such an arrangement, in order that the train may pass over them safely, and in the case of the switch being placed improperly, the train not being liable to be thrown off the rails. My patent switches are formed in such a way as to meet this latter case, and have this additional value attached to them, that a train may pass over them in both directions at full speed with perfect security, the switch being so made as to form a perfect and unbroken line, whether laid for the main line or cross line: my patent point or crossing is likewise so made as to require no cut in the line, nor a guard-rail in the main line; both these contrivances are in use, and when they are more generally known, the practice under discussion will be, it is trusted, altered.

It is likewise self-evident, that if sidings of this form be placed at intervals along the line, swift trains may pass slow ones with perfect facility by the slow train entering the siding, and leaving the main line open to the fast train; thus neither train need stop, nor would there be any further delay than a slight retardation of the slow train whilst the switches were altered; but supposing a man kept on the ground on purpose to effect this alteration of the switch, there would be no necessity to reduce the velocity of either train.

Here, again, therefore, a very general and very judicious regulation might be introduced applicable to all railways.

Admitting the deep interest which railway engineers *ought* to have, and the deep breeches-pocket interest which railway directors *must* have in the perfect working of railways, there is another interest which the Committee was not, perhaps, aware of operating most powerfully against the introduction of improvement, and that is the jealous and selfish feeling of engineers against adopting the contrivances of a contemporary, however useful such contrivance may be, their interest is to let well alone, and to keep without censure.

It is surprising it did not occur to Mr. Brunel that in the case of a public officer recommending to one company the adoption of a valuable improvement made by another, the two parties would be in the same relative position in the event of the compliment being returned, by the first being required to reimprove its own improvement, because, if it were proper in one company to go to an expense to effect a certain object, it is still their duty and interest to incur expence to perfect their arrangements; perhaps he may not be aware how large a comparative amount of profits is sunk amongst manufacturers to perfect their processes, when the spur of competition urges one man to surpass his neighbours, but in the case of railways the same feelings do not operate, which is the most powerful reason of all others why this want should be supplied by the interference of the legislature.

I agree with Mr. Brunel that buffers are matters of secondary importance, and I hold them only useful to protect the carriages from injury when they are knocked about in the station; for any purpose of benefit to a train when in motion, I never could discover, inasmuch as the action and reaction of the engine and trains is fully provided for by the springs connected with the drag links, in fact, were carriages provided with merely two springs acting in reverse ways, so that when the carriages are arranged in trains, a buffer spring connects one end of the links, and a drag spring the other, and supposing the link inflexible, the most perfect ease would be produced in the carriage, and every provision made for any sudden retardation to which the carriage will be subjected. However, a buffer is a buffer, whether formed by springs or hair, or by any other elastic means.

Had Sir F. Smith been simply a man of invention, without any connexion with the Board of Trade, and had he not the means of making his suggestions respected, his treatment from railway companies and railway officers would have been the very reverse of that he has found it, and the fact that his suggestions are treated with respect is a most powerful reason that the public supervisor should be the vehicle through which suggestions should be made, otherwise my experience and that of numberless other men prove that their thoughts and their time will be exerted in vain, in fruitless appeals to railway companies or their agents.

Mr. Brunel's objection to the 15 minutes interval is fair and well-considered; such an arrangement is wholly impracticable, and if adopted might lead to accidents in another point of view than that stated: a train might break down a few minutes after it had left a station, the guards and engine-men might be killed or disabled, then supposing the night dark or foggy, the succeeding train would run upon it, and very sad results would ensue: but if signals such as I have contrived were adopted, and which have been since ably recommended by Sir George Cayley, formed in such a way that the engine should make its own signal, and leave notice a mile behind it, whether it had passed or not the next signal post a mile in advance; the engine man would be thus certain of being informed of the state of the line in advance, and supposing any disarrangement of the signal, no delay or embarrassment would arise beyond the caution necessary in proceeding a mile forward, or perhaps one or two minutes in that distance. This objection is, I conceive, conclusive against any signals acting by time, as it would most infallibly fail at those times it was wanted, viz., in cases of accidents in bad weather. Whilst upon the question of signals, I cannot but advert to the evidence of Mr. Entwistle on this subject; that more accidents have not happened upon the Greenwich Railway is indeed a most providential circumstance; what would become of the trains in the case of a foggy night, with a bleak driving storm of rain or snow and wind from the north-west, and what security would there be that the men would hear the approach of a train and pass it, supposing a Croydon train was coming from London, time enough for either the Croydon train to pull up, or the Greenwich train from Greenwich to do so, or both: because, assuming that Mr. Entwistle's 15 men were most advantageously disposed of, placing 5 men from the junction towards London, and 5 towards Greenwich, the other 5 towards Croydon, the men on the London side would have to pass the word 400 yards towards Greenwich before the Greenwich train could be advised, and then either the one or the other would require to be brought to a dead halt within 200 yards, or a collision would ensue. I very much doubt whether Mr. Entwistle would not have been puzzled had the question been put to him, when was the last occasion that he was aware that this plan had been adopted, and how many times since he had been a director of the Greenwich Railway?

My experience tells me that if Mr. Brunel employs a break to his tender and engine-wheels of sufficient power to drag or stop the wheels, he will very soon destroy both the wheels and engine and railway. If any one thing has been settled in the management of a railway, it is this very fact, that, to block the wheels is to wear a flat place in the circumference, which, whenever the break is applied, allows the wheel to revolve until this flat place comes in contact with the rail, and which, by every successive operation, becomes worse, then, when the break is released, the flat side strikes the rail with a violent blow, and to such an amount that I have known one case on the Greenwich line when nearly a dozen rails were broken, on one occasion, by a bad wheel, the cause of which arose from this most vicious practice; if, therefore, Mr. Brunel realizes his notion, he will have good reason very soon to alter his plan. It is unquestionably a good plan that a large rubbing surface should be opposed to the momentum of the train, but that this should be sought, not by blocking, destroying the wheels, but by an independent method, similar to that I have already patented, and published in your Journal.

Mr. Brunel's opinion of the class of men for engine drivers, and his disposal of book principles amongst them, is most excellent, both in its substance, and in the way he defines it. I cordially and fully assent to all he says on the subject, and only wish, for his own reputation, he could always see his position as clearly and state it as cleverly as he has done in this instance.

In thus fully and freely criticising the evidence of Mr. Brunel, I trust that gentleman will do me the justice to believe that the importance attached to his opinions is my apology for subjecting those opinions to rigid review, and the object of the Committee, viz. to provide for and secure the public safety, renders it a duty of every well-wisher to railways to use his best efforts to assist such object. I purpose continuing my observations in your next paper; meanwhile

I remain, Sir,

Your obedient servant,

W. J. Curtis.

July 22.

REMARKS ON MR. BARRETT'S OBSERVATIONS ON BARS, &c.

Sir—I have read in the July number of your Journal some observations by Mr. Barrett, on Mr. Brook's New Theory of Bars. Not having had time to peruse the work of the latter gentleman, I shall not presume as yet to form any opinion upon it; nor do I mean at present to make any remarks on Mr. Barrett's paper further than relates to a particular passage. Mr. Barrett says, "at the Neva, Gulf of Finland, the Narva, Dantzic, the Danube, the Nile, and many other places, the current without intermission (there being no *flood tide*) is perpetually running out at the rate of six, seven, or eight knots per hour, and yet the old entrances to these rivers have been blocked up by impassable bars, &c."—On this passage I will take the liberty to observe in the first place, that it presents one among too many examples of the confusion arising from hasty writing. Thus the names of rivers are mixed up with those of places in a way to render the writer's meaning rather doubtful. I presume, however, Mr. Barrett means to say—the Neva, at its effluence into the Gulf of Finland, the Narova, (not the Narva, which is a town) also at its egress into the Gulf of Finland, the Vistula (not named) at Dantzic, the Danube and the Nile at their entrance severally, into the Black Sea and into the Mediterranean.

And again, when Mr. Barrett says, "the currents of these rivers (at their embouchures understood) is perpetually running out at the rate of six, seven, or eight knots per hour, there being no *flood tides*," we are at a loss to understand whether the six, seven, or eight knots, refer severally to any three of the five rivers, and if so, to which respectively, or whether the writer means that each of the five rivers has a current constantly running out without impediment, at the rate of from six to eight knots an hour, according to the season. The latter meaning seems to be the most rational. Now, with all due deference, I would observe, that the rivers mentioned differ so essentially in their characters that their currents must be very dissimilar, as must also the quantity and the quality (as regards sedimentary matter) of their waters. As to the Neva in particular, I know not whence Mr. Barrett has gleaned the incorrect information as to the rapidity of its current; but I beg leave to assure him, on the best authority, that its ordinary velocity, so far from being from six to eight knots per hour, is 27 inches per second, or $2\frac{1}{10}$ knots an hour. I cannot state with equal confidence the velocities of the other rivers at their embouchures, neither could I point out, without taking up much more room than you have to spare, the several particulars in which the rivers mentioned differ from one another; nor is it essential to my present purpose. The point to which I would specially draw attention is this.

According to Mr. Barrett, it is the deposit, by the outflowing waters of rivers, of the debris with which they are charged, that forms bars, whether there be tide or not, and in proof of this assertion, he gives as an instance among other rivers, the Neva. Now admitting the general correctness of his views on the formation of bars, it must be confessed he has been most unhappy in mentioning the bar at the mouth of the Neva as a case in point. The fact is, the Neva, of all rivers in the world, is the least obnoxious to the reproach of forming a bar to prevent ingress; on the contrary, she does all she can to open her mouth and invite entrance. True, there is a bar, but the materials of that bar are brought *not by the river* but by the sea.

The Neva at St. Petersburg is 50 feet deep, and, having deposited all impurities in the immense Ladoga, its waters are at all times, except when a strong wind blows in from the seaward for any continuance, as clear as crystal.

The head of the Gulf of Finland narrows gradually to the very mouth, or rather mouths of the river: accordingly when a strong wind blows in from the Gulf, a sea is soon raised whose waves, being pent in, cross and break, and, with the sand stirred up from the bottom rush for escape to the open mouths of the Neva, where being met by the obstacle of the descending current of the stream (bearing along in its main stream a mass of 116,000 cubic feet of water in a second) there naturally results an annihilation of force and a deposit or bar of sand. This being the fact, I am sure Mr. Barrett will see the impropriety of bringing in the Neva in support of an argument to which it does not apply.

The truth is, a bar or deposit will ever be formed where two bodies of water meet, and one or both is charged with detrital matter; but in many cases it is the *sea*, and *not the river* which furnishes the whole of the material of the bar, and in almost every case, I believe, it brings its quota to the mass.

In conclusion, Sir, for I have already trespassed too far, I would say, the subject of bars is a most interesting and a most important one; but those who discuss it cannot be too careful in the choice of facts in support of their arguments if they would not furnish weapons against themselves.

I am, Sir, your most obedient servant,

J. R. Jackson.

P.S. As connected with the subject of bars and sand-banks, I cannot refrain from adverting to a common error which is being continually repeated by persons writing on these matters, viz., that the sand of rivers and that on the sea beach, results from the trituration of the stones rolled by the stream or agitated by the waves. Now Mr. Editor, it is physically impossible that sand can be formed in this way. Sand is an original formation, and all that running water and waves do or can effect is, to wash away the lighter matter, and leave, or carry away, and deposit the sand in particular places. Trituration in the beds of rivers and on the beach, will wear away stones and rocks and polish them, and the result will be a fine impalpable powder, but not one particle of sand will be formed in the process, were it to continue till doomsday. It is high time this egregious error was exploded, an error which could never have gained credit but for that unaccountable indolence of mind which leads so many to take every thing for granted without a moment's reflection.

J. R. J.

ON CANDIDUS'S REMARKS ON THE LECTURES OF THE PROFESSOR OF ARCHITECTURE.

Professors, whether of architecture or any other art or science, are undoubtedly public men, and as such are open to the most unlimited criticism; but, by the same rule, the critics must submit to be attacked in their turn, if any one of the public should think proper. But it should be remembered that abuse is not criticism, and that more effect will be produced by clearly pointing out errors than by the use of "damnable" expressions, which is the style I alluded to, and which will be found scattered occasionally through the fasciculi. I should not, however, have noticed it, had not Candidus been so much in the habit of boasting of his freedom of speech, which, however, by his own confession, avails but little, as it is evident he might as well "try to tickle a rhinoceros with a rose leaf" as attempt, with a one Candidus power, what it would require sixty to effect.

The possibility of treating Gothic architecture properly so as to conduce to comfort, is still unproved. I find repeated the bare assertion of the necessity for treating it with intelligence and ability, but no evidence produced to show that the greatest ability can lead to satisfactory results.

If no more was to be expected from Grecian and Roman than is to be found at the British Museum and other works by the same architect or others of his school, I should then call for Gothic or any other style to save us from such insipid abortions, which are, at any rate, as bad as facsimilies of Gothic, and much worse, inasmuch as they have been so much more often repeated; but I have a higher opinion of the resources of those styles than to believe such to be the case, and from some former remarks of Candidus, I think he will agree with me in that point at least. I shall make no comment on the preference apparently given to the spire of St. George's, Bloomsbury, over that of Bow Church; such an assertion would require more boldness than even Candidus is gifted with—it can therefore be only a mischievous insertion of the printer's devil.

Barry has taken up Gothic architecture with an originality of conception to be found in no other architect—but even his success will not warrant the assumption that we shall ever be able to incorporate the principles of the style with the habits of the present day. At the period at which this style flourished, it followed a regularly progressing course, commencing with the Norman. This was gradually improved upon till it resulted in the early English, which, by further modifications, became that of the decorated period, the most perfect of all. From that time it increased in richness and exuberance, but declined in purity till it was worn out in the reign of Henry VIII. Now I cannot see how we can, with advantage, dip down into any one of these styles at pleasure, and follow it out in the spirit in which it was then followed, and in which is the only hope of success. It is like transporting the trees of the tropics into this country, where only the most assiduous attention can keep them alive—nothing can ever make them equal in beauty the natural growth of the trees of our own forests, though in their native climate they may as much surpass them as they now fall short.

S. L.

THE ROYAL ACADEMY.

SIR—I am very glad to perceive that painters as well as architects, are at length beginning to remonstrate against the truly preposterous system of hanging pictures and drawings at the Royal Academy. Let us hope that what has lately been said on the subject both in your own Journal, and the Art-Union, will now shame the Academy into common sense, and deter them in future from taking in more works than can be properly seen when hung up.

Of course this would contract their catalogue to about one-half its present extent—in which case it might be sold to the public at half its present price,—but both the public and artists would be benefitted by the reduction—I do not mean of the price of the catalogue, but of the dense throng of pictures and drawings, the majority of which are annually put out of sight, by being *exalted* to disgrace—to their own disgrace and to that both of the Hanging Committee in particular, and of the Academy generally.

Still it is very doubtful whether the expostulations and remonstrances that have been made will produce any effect, unless repeated from time to time, and dinned in the ears of the Academicians, until they can no longer affect to be ignorant of them. Did the matter rest entirely with the President, the evil complained of would no doubt be remedied at once, but I suspect that like some other great personages, he is no more than "the puppet in the chair," and permitted to fill it on the condition of his napping in it, and not interfering with those around him. Though those composing them may be well-intentioned and reasonable people, corporate and public bodies are almost invariably shameless, and do not scruple to do in their united capacity, what hardly one among them would dare to sanction, defend, or justify individually and personally.

In the course of his remarks, the writer in the Art-Union attributes some portion of the present absurd system of hanging pictures in our public exhibitions, to the want of better contrivance and arrangement on the part of architects who build the rooms. Herein he is partly right, but he is assuredly mistaken if he supposes that, as far as architectural appearances is concerned, any thing would be lost were the rooms to be designed in such a manner as to render it impossible to put any pictures at more than a moderate height above the eye. On the contrary, as much might be gained in point of architectural effect as of positive convenience; since it would not be at all requisite that the proportions of the rooms, as to height, should be altered, or their ceilings an inch lower than at present. All that would be necessary is that no more than a proper altitude should be allowed as the available space for hanging pictures on the walls, (which might vary in the different rooms accordingly as they are intended for small or large paintings); and from that height the architectural decoration of the upper part of the walls and ceiling should commence. By this means the general appearance would be very greatly improved; and instead of the broker's-shop and picture-dealer's-warehouse look, which now so disagreeably characterises all our exhibition rooms, there would be an air of elegance and spaciousness,—of there being room enough and to spare without *stowing away* a number of pictures, piling them up to the very ceiling, when they might just as well be poked into a lumber garret at once.

In short, let the Academy and other exhibiting Societies break up their *Lumber Troop* corps, dismiss their host of supernumeraries, and instead of surfeiting their visitors with an annual cram—consisting of a good deal of trash, give us much less as to quantity, and much more as to quality.

I remain, &c.,

COMMON SENSE.

PILBROW'S CONDENSING CYLINDER STEAM ENGINE.

THIS is a contrivance intended, according to a pamphlet written by Mr. Boyman Boyman, to save the loss of power occasioned by the imperfect exhaustion of the cylinder in steam engines of the ordinary construction, and by which Mr. Pilbrow considers that he will save *more than half* the fuel of Mr. Watt's Rotative engines. The author of the pamphlet in question, however, dispels at the very outset the illusion as to the extent of saving by stating that Mr. Watt estimated the mean resistance of the unexhausted steam at 4 lb. per square inch, in an engine loaded so as to exert its intended power, the steam being 2¼ lb. less than the atmosphere. In this case the pressure of the steam is 2¼ lb., from which deducting 4 lb. for imperfect exhaustion, and 1¾ lb. for friction (as at page 28) there remains an effective pressure of 6·46 lb. The pressure in the condenser at a temperature of 100° is 1 lb., therefore the limit of what may be saved by Mr. Pilbrow's arrangement is 3 lb. per square inch, which is the entire loss resulting from the exhaustion in the cylinder being less perfect than in the condenser; but if the whole of this were saved, the load of the engine being increased, the friction would be so likewise, and the effective pressure would become, say 9·09 lb., and the saving of fuel would be less than 29, instead of more than 50 per cent., as anticipated by Mr. Pilbrow. It is evident that the loss in question would not rise in the same proportion as the pressure of the steam employed, particularly when it is expanded in the cylinder, which is now pretty generally done to a greater or less extent, and we are persuaded that Mr. Farey must have overrated the resistance of the unexhausted steam, where it is used at 3¼ lb. above the atmosphere, when he estimated it at 5·71 lb.; but even with this allowance the consequent loss of duty amounts to no more than 20 per cent. It should be observed that this is the *whole* loss due to imperfect exhaustion in the cylinder, which can certainly not be saved by Mr. Pilbrow's arrangement, though he considers that it is.

Little need be said of the theory of condensation, as it is called, laid down at pages 19 and 20, which is very little of a theory, and nothing at all to the purpose; but since it is dragged in, as it were, in confirmation of the advantages of the Condensing Cylinder Engine, we shall merely show that the inferences intended to be drawn from it are erroneous.

The theory of condensation is that "steam can only be condensed as fast as it rushes from the cylinder to the condenser, as far as the injection can enter, and as fast as the water, or cold surface, can absorb all the caloric of the steam." Mr. Boyman concludes that "if the vacuum gauge shows, whilst the steam is being condensed, a less mean vacuum in the condenser than what is due to a temperature of 100°," (considered by Mr. Watt as a fair average), "it shows that the steam has flowed quick enough to the condenser, and is there waiting to be condensed," and that "no increase of eduction valve would, therefore, cause a quicker annihilation of the steam, to give a better mean exhaustion of the cylinder, for it is already large enough to permit its escape as fast as a certain quantity of water can take up its caloric." But what is the just conclusion to be drawn from the above circumstance?—Simply that there is not sufficient injection water to reduce the condensement to the required temperature; a knowledge of the actual state of exhaustion in the cylinder would alone show whether the steam flowed fast enough into the condenser. Mr. Boyman harps continually on one string—the impropriety of reducing the condensement to a lower temperature than 96° or 100°, and pretends to conclude therefrom that no better cylinder exhaustion than was obtained by Watt can be achieved with the ordinary air pump, separate from the condenser.

The long discussion of the comparative performance of Mr. Watt's rotative engines and the present is irrelevant, and we shall therefore discuss it with one or two remarks.

After extracting Mr. J. S. Russell's proof of the fallacy of the opinion that the better the vacuum the greater is the duty, the author informs his readers that "the above formula is given because it confirms the general principle, that more is lost than gained by a vacuum *beyond certain limits*. It does not embrace," he says, "the principles of condensation, but has reference simply to temperature; not," he continues, "that this theory is supported by the practice of Cornish engines, where the greatest duty is performed with the greatest vacuum."

If, then, this theory is not supported by facts, how can it be said to confirm the general principle?

In speaking of the *extraordinary* Indicator diagrams of the present day, (which seem to puzzle Mr. Boyman exceedingly, because they show that Mr. Farey's observation, made 14 years ago, is not applicable to engines of the present day, namely, that "the modern engines are, by their construction, less capable of speedy exhaustion of the cylinder than the original construction"), he mentions that in the diagrams of the *British Queen*, where a mean cylinder exhaustion of 12·5 lb. is shown, the condensement is reduced to the temperature of the external water, but he does not seem to be aware that *the condensing water left the condenser at a much higher temperature*, which it must have done, or it could not have condensed the steam. It is however certain that, whatever may have been the state of the vacuum in the upper part of the condenser, where the steam from the cylinder entered i t the mean difference between it and the mean cylinder exhaustion *cannot possibly* have amounted to 2.41 in., the external barometer standing at 30 inches, as that would indicate a perfect vacuum, which is obviously impossible.*

In Mr. Pilbrow's engine the ordinary condenser and air pump are replaced by a double-acting air-pump of the same size as the steam cylinder, called the condensing cylinder, in the interior of which the condensation is effected by injection alternately above and below the piston, which is of course solid, like the steam piston. The two cylinders are connected at top and bottom by passages, with valves to open and close the communication alternately. The action will be as follows: while the steam piston is ascending, the air-pump piston is descending, and the two cylinders communicating at top, the steam which performed the previous down stroke will flow into the condensing cylinder, and be condensed by the jet, by which, as we know from the experience of ordinary condensing engines, the vacuum above the air-pump piston will be maintained at nearly its maximum, while the exhaustion of the cylinder will be nearly the same as in ordinary condensing engines. Mr. Boyman however supposes that, "during its condensation, the uncondensed steam will keep giving to the condenser piston, until completely annihilated, just as much power as it offers resistance to the effective action of the steam piston." The exhaustion on the under side of the condenser piston will be the maximum throughout the stroke, so that the resistance to the motion of the steam piston (exclusive of friction and the resistance to the discharge of the condensement in the latter part of the stroke) will be equal to the mean pressure of the used steam remaining in the steam cylinder *minus* the difference between the maximum and mean exhaustion in the condenser, and this difference, which is quite insignificant, is, after deducting the surplus power required to work his large air-pump, the true gain of power obtained by Mr. Pilbrow's contrivance, and we think it probable that after the deduction the gain will be found to be negative, or a loss.

CARBONIC ACID GAS VERSUS STEAM.

(From "Buckingham's America.)

Towards the close of our stay in Philadelphia, I had an opportunity of attending one of the chemical classes of my friend Dr. Mitchell, and witnessing there a most interesting experiment for the rendering carbonic acid gas solid, and for producing by it a degree of cold, extending to 102 degrees below zero, on the scale of Fahrenheit's thermometer. The materials, first confined in a strong iron receiver, were, super-carbonate of soda and sulphuric acid, in separate divisions; the whole was then powerfully shaken, so as to be well mixed or incorporated, and this operation continually evolved the gas, till the whole vessel was filled with it in a highly condensed state.

An instrument not unlike a common tinder-box, as it is used in England, but about twice the size, and with a small tube of inlet passing through its sides, was then fixed by this tube to a pipe from the receiver. The inside of this box was so constructed as to make the gas injected into it fly round in a series of constantly contracting circles, which was effected by projecting pieces of tin at different angles, fastened around the sides of the interior. The gas being then let out by a valve, entered this box from the receiver, making as loud a hissing noise as the escape of steam by the safety-valve of a large boiler, and in about three or four seconds the emission of the gas was stopped.

The box was then taken off from the receiver and its cover opened, when it was found to be filled with a milk-white substance, in appearance like snow, but in consistence like a highly-wrought froth, approaching to a light paste. It was surrounded with a thin blue vapour like smoke, and was so intensely cold, that the sensation of touch to the fingers was like that of burning; and the feeling was more like that of heat than cold. The slightest particles of it dropped on the back of the hand, and suffered to remain there, occasioned a blistering of the skin, just like a scald; and some of the students of the class who attempted to hold it in their fingers, were obliged to let it drop as if it were red-hot iron.

Some liquid mercury, or quicksilver, was then dropped into a mass of this "carbonic acid snow," as it was called, mixed with ether, upon which it instantly froze, and being taken out in a solid mass, it was found to be malleable into thin sheets under the hammer, and capable of being cut up like lead, with a knife or large scissors. As it became less cold it grew more brittle, and then, when pressed strongly by the thumb or finger against a solid substance, it was found to burst under the pressure, with a report or explosion like the percussion powder.

A small piece of this carbonic acid snow was placed on the surface of water, where it ran round by an apparently spontaneous motion, and gave out a thin blue vapour like smoke. Another piece was placed under the water, and kept beneath it, when it emitted gas in an immense stream of air-bubbles, rushing from the bottom to the top; thus returning, in short, from its solid to its original gaseous condition. Some of the snow was then mingled with the well-known "freezing mixture," and by stirring these both together, a degree of intense cold was produced, extending to 102 degrees below zero, and there remaining for a period of ten or fifteen minutes; though the weather was extremely hot, the thermometer standing at 94 degrees in the shade, in the coolest parts of Philadelphia, and being at least 90 degrees in the lecture-room itself.

The practical application of this discovery to the propelling of engines in lieu of steam, was then exhibited to us. A model of an engine of the ordinary kind now in use for mines, manufactories, and steam-ships, was placed on the table before the lecturer. A metal tube was then screwed on to the pipe and valve of the receiver, in which the condensed carbonic acid gas was contained, and the other end of the tube through which the gas was to escape, when let into it from the receiver, was applied to the wheel of the model engine; the gas was then let out, and the rushing torrent of it was such as that it propelled the engine wheel with a velocity which rendered its revolutions invisible, from their speed, making the wheel appear stationary, though in a trembling or vibratory condition, and rendering all perception of the parts of the wheel quite impossible till the gaseous stream which gave the impetus was withdrawn.

Dr. Mitchell expressed his belief that this power might be made to supersede entirely the use of steam and fuel in navigation, and thus overcome the greatest difficulty which has yet impeded long voyages; he thought it might effect the same salutary change in manufactories where engines are used, so as to remove the greatest nuisance, perhaps, of all manufacturing towns, the immense quantities of smoke which darken the atmosphere, and destroy the cleanliness of places, persons, raiment, and dwellings. He founded his belief on the expansive power of this gas when brought into a highly condensed state, such as we saw it, and the practicability of bringing this power to act upon engines of any size by land or by sea. For the latter purpose he suggests the use of iron tanks, made with the requisite degree of strength, to act as receivers; these being fitted to a ship's bottom, along the keelson and the inner floor of the hold, as the iron water-tanks of ships of war are at present, it may be placed on board vessels intended to be propelled by engines, in such quantities as the length of the voyage may require; communications from these tanks, by tubes of adequate size and strength, would then have to be made to the engines, and placed under the complete control of the engineer, as the steam-power is at present. The expansive power of the condensed gas, and its pressure outward, or tendency to escape, being the same in its nature with steam, but greater in degree, the application and direction of this power would effect all that steam now does, and thus supersede the use of fuel, with its inconveniences and accidents, entirely.

In reference to the expense, Dr. Mitchell had made such calculations as to satisfy him that it would be cheaper than the present materials of steam navigation. The Great Western steamer, in coming from London to New York, actually consumed 600 tons of coal, which, at the lowest possible estimate, could not cost less than £1000 sterling, or 5000 dollars. But as it was necessary to provide for a longer voyage than that actually performed, in case of accident or delay, no less a quantity than 800 tons were taken on board, and consequently 800 tons of space were wholly lost, or rendered unproductive, by its appropriation to fuel. The expense of the requisite quantity of gas for such a voyage, including all the fittings, would not, he thought, exceed that of the coals and requisite machinery; and the saving of the space, for freight, would be a source of considerable profit; while the avoidance of the heat and smoke, inseparable from fuel and steam, the absence of boilers and chimneys, and the safety from accidents of bursting and taking fire, would be all such high recommendations to passengers, that none would venture to embark in steam-ships while those propelled by carbonic acid gas were available.

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

INSTITUTION OF CIVIL ENGINEERS.

March 16.—The President in the Chair.

"*Description of two Wrought-Iron Roofs over the buildings at Mr. Thomas Cubitt's Works, Thames Bank.*" By Mr. Adams.

This communication describes in detail the construction, and gives the dimensions of the several parts of two fire-proof roofs of 29 feet span, one of which bears, in addition to the covering, a ceiling of tile arches upon iron girders, the weight of which is equal to 5 tons 4 cwt. upon each truss.

The paper is accompanied by two drawings of the roofs.

"*Description of a Double Telescope Theodolite.*" Arranged by Nathaniel Beardmore, Grad. Inst. C.E.

The improvement in this theodolite consists in its having a second telescope fixed over the ordinary one, in a reverse position, so that the line of collimation of the two telescopes when properly adjusted should be the same. The principal advantage gained is, that a straight line may be carried out with perfect accuracy, without the tedious and uncertain process of adding 180

* It may be as well to observe here that the difference between the exhaustion in the cylinder, and in the condenser is independent of the mode of condensation; and that consequently, if by any improved process the vacuum in the condenser be increased, the cylinder exhaustion must be so too.

degrees to the observed angle and reversing the instrument. A drawing of the instrument accompanied the communication.

"On setting out Curves for Railways." By R. C. May, Assoc. Inst. C.E.

The method of setting out curves proposed in this communication is founded upon the 32nd Prop. of the 3rd book of Euclid. It consists in cutting off by a chord a segment of the circle to be described, and then finding any number of points in the curve by means of a reflecting instrument, which is set so as to reflect the angle in that segment.

The instrument which has been adapted by the author for this operation, consists of two plane mirrors, the upper one being fixed vertically upon a disc of brass, and the lower one fastened to an arm which turns upon its centre, and permits the two mirrors to be set at any angle with each other: the arm can be fixed by a clamp screw. In the case surrounding the mirrors are two holes, for admitting light, and between them is the sight hole, placed so as to bisect the angle formed by the mirrors. From the underside at the centre of the instrument is suspended a slender wooden rod, with a pointed end, weighted with lead.

Angles are taken with the instrument in the same manner as with the box sextant. To determine any point in the curve, the instrument when set fast is placed in such a position that the two given objects coincide in the mirrors, and the weighted rod being released by withdrawing a bolt, falls directly beneath the centre of the instrument, marking the required point in the curve.

The author presented with this paper a Reflecting Instrument, and field tables of chords and segments to be used in setting out curves by this method.*

"An improved Plank Frame, for sawing Deals and Planks of various thickness into any number of boards." By Benjamin Hick, M. Inst. C.E.

The principal improvement in this machine is a novel kind of gearing for producing what is usually termed the "taking-up" or "traversing motion" of the plank during the operation of sawing.

A revolving motion is given to two pair of coupled vertical fluted rollers, by means of worms and wheels, which are worked by a ratchet wheel and catch, from the crank shaft of the machine. When a plank is introduced between the moving rollers and the fixed guides in the centre of the machine, the tendency of the motion is to draw the plank forward at each stroke, with a force exactly corresponding to the degree of resistance opposed by the teeth of the saw. By this means, the necessity of any other support or side roller to the plank, during its progress through the machine, is avoided, and any number of planks of different length, depth, and thickness, can be put through the machine after each other, without any alteration or stoppage of the work.

Several minor improvements are introduced in the general arrangement of the machine, particularly in the position of the crank shaft and connecting rod, which latter is placed in the centre of the moveable frame, occupying a space which has not hitherto been made use of in machines for cutting two planks simultaneously; and by carrying the crank shaft upon the framing, instead of having it fixed upon a separate foundation, the construction is simplified as well as rendered less expensive.

The communication was accompanied by a working model of the machine.

"An historical Account of Wood Sheathing for Ships." By J. J. Wilkinson.

This communication commences with the earliest history of naval architecture, the different modes of construction, and the precautions taken for the preservation of the vessels from the attacks of marine animals.

A very early instance of extraordinary attention to the preservation of the bottom of a vessel appeared in a galley supposed to have belonged to the Emperor Trajan, A. D. 98 to A. D. 117, which was found in the fifteenth century in the lake Hemorese (or Lago Riccio), in the kingdom of Naples, and was weighed after it had probably remained more than 1300 years under water; it was doubly planked with pine and cypress, coated with pitch, upon which there was a covering of linen, and, over all, a sheathing of lead fastened with nails of brass or copper; the timber was in a perfectly sound state.

In the reign of Henry VIII. large vessels had a coating of loose animal hair attached with pitch, over which a sheathing board of about an inch in thickness was fastened "to keep the hair in its place."

It is believed that the art of sheathing vessels was early practised in China: a mixture of fish oil and lime was applied; it was very adhesive, and became so hard that the worm could not penetrate it.

The opinions of Sir Richard Hawkins, of François Cauche, and of Dampier, on the practice of wood furring, are then given at length, with extracts from their journals.

The sheathing the bottoms of ships with timber, appears to have been disapproved by these early navigators. In 1668, the officers of the fleet, then preparing under Sir Thomas Allen for an expedition against the Algerines, petitioned that their vessels might not be thus encumbered, as they were in consequence always unable to overtake the light-sailing unsheathed vessels of the enemy; the petition was granted, upon the condition that precautions should be taken by cleaning the ships' bottoms very frequently.

In 1670 a patent was granted to Sir Philip Howard and to Major Watson, for the use of milled lead sheathing; it was not, however, introduced without difficulty; nor until an order was issued that "no other than milled lead sheathing should be used on his Majesty's ships." About the year 1700 the lead was acknowledged to have failed, and wood sheathing was again introduced.

Numerous instances are given of the employment of wood as sheathing for ships in celebrated expeditions: the ravages of the worm, the accumulation of barnacles and weeds, are then described; the qualities of the wood employed for sheathing in different countries, both formerly and up to the present time, are examined, and the author, who undertook the investigation of this subject in consequence of finding how little good information existed in an accessible form, promises the history of metal sheathing in a future communication.

"A Machine for bending and setting the Tire of Railway Carriage Wheels." By Joseph Woods, Grad. Inst. C. E.

The usual mode of bending tire bars was by means of swages and hammers round a fixed mandril; after being welded, they were stretched on a cast-iron block formed of two semicircular pieces hinged at one point, and wedged apart at the opposite side; the hoops being heated were placed on this block, and by repeated blows driven into close contact with the mould.

Much difficulty was experienced in thus making up tires for large railway wheels, and the present machine was constructed for facilitating the process.

One end of the tire bar when heated is wedged into contact with one of four segments of a circle, of the required diameter, upon a cast-iron table, which is caused to revolve slowly; the pressure of a guide wheel at one side forces the tire bar to warp round the segments, and to form the circular hoop required; its ends having been previously scarfed, are then welded together.

The tire is again thoroughly heated and placed around the four segments, which slide radially on the table, and are then simultaneously forced outwards by a motion of the centre shaft.

The tire being slightly chilled, and assisted by the swage and hammer, soon adapts itself to the segments, and forms a circular hoop instead of two semi-circles irregularly joined at their points of contact, as by the old system; it is then ready for being chucked on the lathe, and bored out before shrinking on the wheel.

It is apparent that a machine of this description becomes applicable to tires of any diameter, by having three or four sizes of segments adapted to the table. It is found to diminish the manual labour, and to prepare the tire more accurately than by the usual process.

A model of the machine, and a detailed drawing of the several parts, accompanied the communication.

"On the improvement of the Roads, Rivers, and Drainage, of the Counties of Great Britain." By Robert Sibley, M. Inst. C. E.

The author had on a former occasion drawn the attention of the Institution to the subject of a Bill before Parliament, "for the better regulation and general improvement of the Drainage of the Country;" and at the same time pointed out the course pursued by the magistrates of the County of Middlesex, in procuring with his professional assistance an accurate account of the Rivers, Bridges, &c., hoping that it might lead to similar surveys in other counties.

In the present communication he investigates the nature of the works which each county may be expected to undertake, and the means of accomplishing them economically, so that real public benefit may accrue.

The objects principally requiring the attention of the county magistrates, he considers to be, First—Facility of intercourse by the improvement of the roads, bridges, rivers, and canals. Secondly—Protection from injury by the passage of the waters from or through the county; and Thirdly—The removal of causes tending to vitiate the atmosphere, or to render unwholesome the water used for the support of human life.

All these points, which do not appear to have been fully comprehended in the Sewage Acts, are examined at length, and suggestions are offered for their regulation, with examples of the effects resulting from their neglect.

The advantage of placing the water-courses of the country generally under a well regulated system of management, is insisted upon as the most effectual mode of guarding against the destruction of property, and not unfrequently of human life, which ensues from the effects of sudden inundations, such as have recently occurred in the county of Middlesex.

March 30.—The President in the Chair.

"Description of a new Universal Photometer." By Dr. Charles Schafhaeutl of Munich, Assoc. Inst. C. E.

The inadequacy of the photometric instruments invented by Pictet, Rumford, and others, is universally acknowledged. The bromide of silver, as used by Sir John Herschell, although extremely sensitive, is only slightly affected by artificial light.

These circumstances induced the author to complete the present instrument,* which he contemplated about twelve years since.

* This paper, with enlarged field tables, has been published by the Author, with the permission of the Council of the Institution, to accompany the instrument.

* The instrument was constructed by Mr. E. M. Clarke, 428, Strand.

The intensity of the undulations of gaseous fluids, as well as that of the air, is proportional to the amplitude of the oscillations, or more properly to the square of the amplitude.

A wave of light striking the retina must create a similar vibratory motion in the nerves of the retina, because the velocity of the molecular movement of the nerves depends upon the force with which they have been struck by the original wave, and if this velocity could be measured, it would show at the same time the intensity of light.

It is scarcely possible to obtain a direct accurate measurement of this velocity, but if the time during which the vibratory motion of the nerves ceases, be ascertained, the velocity of the vibrating molecules, and therefore the intensity of light, may be determined; because the duration of an impression on the retina is dependent on the resistance which the molecules of the nerves oppose to every force striking them; but as this resistance of the nerves increases as the square of the velocity, four times the momentum or intensity is necessary to double the time of duration; or, in other words, the intensity of the pencil of rays is as the square of the time of the duration of that impression made on the nerves of the retina.

The new photometer consists of a brass bar fixed vertically in a stand, carrying at its upper end a small tube in two parts, which may be lengthened from 5 to 10 inches if requisite. This eye tube has at each end a sliding plate pierced with holes of corresponding diameters. From the bottom of the bar a projecting arm sustains the lower end of a strip of rolled steel 18 inches long, $\frac{1}{10}$ths inch broad, and $\frac{1}{32}$nd inch thick; this has at the upper end a thin plate pierced with a small hole, corresponding with the holes in the sliders, and standing $\frac{1}{4}$th of an inch from one of them: upon the main bar is a prism with a slit in it, through which the strip of steel passes; this prism can be moved up or down by a rack and pinion, so as to lengthen or shorten the vibrations of the strip.

The method of using the instrument is to adjust the two holes at the opposite ends of the horizontal eye tube, so that they perfectly correspond, and do not permit any rays of light to enter, unless the plate at the extremity of the spring be pushed aside. The light to be compared is then placed at a certain given distance behind the plate, so that by bringing the axis of the hole which is pierced in it into the axis of the tube, a small pencil of light may enter the pupil of the eye. The prism is then placed at 100 of the scale on the side of the brass bar, and the steel strip caused to vibrate gently. A luminous disc immediately appears, accompanied by scintillations, which are caused by the impressions on the retina being interrupted by dark intervals: the prism is then gradually raised until the length of the vibrations of the strip being diminished, and the velocity increased, the luminous disc appears perfectly steady and clear. The length of the vibrating portion of the strip is then read off by the verniers marked on the brass rod, and compared with the whole length of the spring, measured from 100, which is considered as unity. The number of the vibrations to be computed from the found length of the spring, are inversely to the numbers of vibrations of the whole length, as the squares of their relative lengths. Hence are constructed the formulæ for calculation, which are given at length in the communication.

A fresh luminous impression is made on the retina as often as the circular aperture in the screen on the top of the spring cuts the axis of the tube. If the duration of the small vibration of the nerves of the retina is shorter than the time of a vibration of the spring, a dark interval appears between the two luminous impressions. In this case the vibration of the spring is shortened until the next impression returns just as the first ceases, and therefore the dark interval disappears; then by measuring the length of the shortened spring, the number of vibrations can be computed, and from them the intensity of the light.

This communication was illustrated by a series of experiments upon different lights, with the Photometer which was presented by the author to the Institution.

"*On the circumstances under which the Explosions of Steam Boilers generally occur, and on the means of preventing them.*" By Dr. Schafhaeutl, of Munich, Assoc. Inst. C.E.

Explosions of Steam Boilers.—In this communication it is assumed, that perhaps not one-tenth of the recorded explosions of steam boilers can be correctly attributed to the overloading of the safety valve, or to the accumulation of too great a quantity of steam in the boiler. The author alludes to the degree of pressure which hollow vessels, even of glass, are capable of sustaining, if the pressure be applied gradually. He found, in repeating the experiments of Cagniard de la Tour, subjecting glass tubes of one or two inches in length, one-fourth part filled with water, hermetically sealed, and immersed in a bath of melted zinc, that they apparently sustained the immense pressure of 400 atmospheres without bursting; but if the end of an iron rod was slightly pressed against the extremity of the tube, and the rod caused to vibrate longitudinally by rubbing it with a leather glove covered with resin, the tube was invariably shattered to pieces.

Hence he concludes, that something more than the simple excess of pressure of steam in the boiler is necessary to cause an explosion, and that a slight vibratory motion alone, communicated suddenly, or at intervals, to the boiler itself, might cause an explosion. From the circumstance of safety valves having been generally found inefficient, he concludes that a force has operated at the instant it was generated in tearing the bottom or sides of the boiler, before it could act upon the safety valve.

From the sudden effect of this force, explosions have been ascribed to the presence of hydrogen, generated by the decomposition of water; but independently of the difficulty of generating a large quantity of hydrogen in such a manner, it could neither burn nor explode without the presence of a certain quantity of free oxygen or atmospheric air; and such an explosive mixture would not take fire, even if mixed with 0·7 of its own volume of steam.*

Sudden conversion of Water into Steam.—The ordinary mode of converting water into steam is by successively adding small portions of caloric to a relatively large body of liquid; but if the operation was reversed, and all the heat imparted to a given quantity of water in one unit of time, an explosive force would be developed at the same moment. For example, if a bar of iron be heated until it is coated with liquid slag, and is then laid upon a globule of water upon an anvil, and struck with a hammer, the liquid slag communicates its caloric instantly to the water, becoming solid at the same time that the water is converted into vapour with a loud report. A similar occurrence may take place in a steam boiler when a quantity of water is thrown into contact with an overheated plate, either by a motion of the vessel or from a portion of the incrustation formed on the bottom or sides becoming loosened. A sudden opening of the safety valve may, under certain circumstances, prove dangerous, or even any rapid increase of heat which would cause a violent excess of ebullition in the water.

An examination is then entered into of the respective powers of water and of steam, to transmit undulatory motion, and of their compressibility. According to Laplace, the conducting power of steam at our atmosphere and 294·1° Far. is 1041·34511 feet per second, and that of water 6036·88 feet. The ratio of these different velocities is therefore as 1 : 4·5.

In cases of a sudden explosive development of steam, the principal action is directed against the bottom or the sides of the boiler, whence, spreading itself through the water, it is finally transmitted through the steam to the safety valve; a wave created by an explosion, even at the surface of the water, would reach the bottom or the sides of the boiler, 4½ times sooner than it would affect the top of the steam chamber; but if it took place at the bottom, the time for the explosive wave to reach the safety valve would be the sum instead of the difference of both velocities. Although these relative periods of time may be considered as infinitely small, it is contended that there is sufficient delay (counting from the moment at which the plates begin to yield) to cause the rupture of the material which would otherwise have yielded by its own elasticity had the time been greater, as all communication of motion is dependant only on time.

Experiments upon Wires.—To illustrate the effect of the sudden development of an explosive force upon the plates of a boiler, the author gives the results of a series of experiments made by him upon iron wires, for the purpose of ascertaining the amount of elongation which took place before yielding under the sudden application of a given weight. The result was, that a wire which had resisted a tension of 22 cwt. when gradually applied, broke invariably, without any elongation, when the same force was suddenly applied by a falling body.

Upon Railway Bars of different qualities.—Similar experiments with railway bars showed that fibrous iron, which supported a gradual tension, broke by the sudden application of the same force; while close-grained iron, which was incapable of resisting the gradual strain, bore perfectly well that of sudden impact. These facts are worthy of consideration in the selection of iron for boiler plates, where the sudden action of the rending force is to be guarded against.

The details are then given of a series of experiments, illustrating in an ingenious model, by means of an explosive mixture of chlorate of potassa, the effects of explosions at different heights within a boiler.

Proposed Safety-valve.—A careful examination of the circumstances, and the results of his experiments, convinced the author that a simple mechanical arrangement, applicable to all boilers, might be introduced, so as to diminish the danger arising from the sudden development of an explosive force. He proposes to connect with the bottom of the boiler, by means of a pipe, an extra safety valve of a given area, loaded to five-sixths of the absolute cohesive force of the boiler plate. In the event of a sudden development of steam, the first shock would act upon the valve and open it, which would have the effect of depriving the wave generated of its destructive force, and at the same time diminish the violence of the second shock from the top of the boiler, having permitted the escape of a portion of the water from the boiler.

The apparatus for conducting the experiments was presented with the communication.

Steam Boiler explosions.—Mr. Parkes stated, that he had been occupied for several years in collecting facts illustrative of the phenomena of steam boiler explosions. These disasters could not all be referred to one cause. A boiler might be too weak to sustain the pressure within it, and a rupture would be the necessary consequence. But though the simple elastic force of the steam might thus occasionally account for the rending of a boiler, that cause was insufficient to explain many well-known phenomena, such as the projection of an entire boiler from its seat, the separation of a boiler into two parts, the one remaining quiescent, the other being driven to a great distance &c. He was of opinion that a very sudden development of force could alone have produced such effects.

Dr. Schafhaeutl had ingeniously shown that an explosive force generated under water would act upon the bottom of the boiler and burst it, before the

* See the author's experiments, Mechanics' Mag., Vol. XXX. p. 144.

safety valve could relieve the pressure. The Doctor deduced from Mr. Parkes's theory of "the percussive action of steam," and his own experiments, that if, from any cause, such as the breaking up of a portion of crust adhering to the bottom of the boiler, a volume of steam of high elastic force was suddenly evolved, a rupture of the bottom would be the consequence, or, the boiler might be separated into two parts. Mr. Parkes coincided in this opinion, and cited several examples in support of it.

It appeared to him that a force different from, and greater than, the simple pressure of the steam, was the principal agent. The Committee of the Franklin Institute, and others, who in their experiments had endeavoured to produce explosions of boilers, had very rarely succeeded, and the effects obtained fell far short of those which continually occurred by accident. It might be safely inferred from this fact, that the experimenters had not arrived at the true cause of the ruptures and projections of boilers, otherwise the production of similar effects would not have been difficult.

Salt Pans.—Describing the sudden development of a volume of steam, from highly heated plates, which no practicable number of safety valves could discharge quickly enough to save a boiler from destruction, he instanced the effects produced by the breaking up of the scale in salt pans. Carbonate and sulphate of lime were separated from brine by evaporation, and adhered very firmly to heated surfaces. A crust of salt frequently formed upon this deposit; the cessation of ebullition (if the deposit occurred over the furnace) was the consequence, and the bottom of the pan became red hot. The manner in which the pan scale was disengaged, was to strike it with the edge of a heavy iron pricker, which allowed the brine to reach the plate; it was also frequently broken through by the expansion and bagging down of the plates, leaving the crust above like an arch. In such cases the plate was seen for an instant to be red hot, and immediately afterwards an immense column of brine was projected from the pan, the steam evidently being of high momentary elasticity. Mr. Parkes had seen a yard square of scale thus burst, the whole surface of the plate being at a glowing red heat. Had the pan been closed, like a steam boiler, he conceived that the blow of the steam on the roof, bottom, or sides, would have destroyed the vessel.

A thin copper salt pan at Mr. Parkes's works, had a hole burst through its bottom by the sudden action of steam thus generated. The spot had no doubt been previously injured by heat. He conceived that similar phenomena might, and frequently did, occur in steam boilers.

Heated Plates.—A theory has been adopted by many writers on the explosion of steam boilers, that red-hot iron plates would generate less steam than plates at a less heat. This was founded on the experiments of Leidenfrost, Klaproth, and others, on the length of time requisite to evaporate a small globule of water in a red-hot spoon. But there was no analogy between the condition of a hot spoon containing a drop of water, and that of a body of water and heated plates in boilers.

Steam of great force would instantly be produced from a thin sheet or wave of water, passing over hot plates, the molecular attraction of a drop falling a short distance upon a plate would be destroyed, and the whole be instantly converted into steam of a high momentary elasticity. The theory of the hot spoon experiment, as applied to boilers, had been demonstrated to be fallacious by Dr. Schafhaeutl in a paper published in the *Mech. Mag.* vol. xxx. No. 799.

"Union" Steamer at Hull.—The explosion of several boilers had been attributed, and Mr. Parkes thought justly, to a wave of water washing over highly heated plates. He believed that the fatal accident to the "Union" steamer at Hull was so produced. The boilers of steam vessels were not at that period so well arranged as at present, for preventing the water from flowing to one side, and leaving a portion of the top of the flues dry with the fire beneath. Under such circumstances, the disaster which occurred would be inevitable, on the vessel's coming on an even keel. Mr. Parkes was not of opinion that it required the exposure of a large area of heated metal to effect the separation of a boiler and the projection of the upper half of it; as, in this case, it was the suddenness of the action, no number of safety valves could have deprived the steam of its instantaneous force, so as to have saved the boiler. The entire circumference of large boilers had been frequently divided as clean as a pair of shears would have accomplished the work. These phenomena were evidences of a force very suddenly exerted.

Sudden actions on the surfaces of boilers arose also from other causes than the heating of plates. During the inquiry into the causes of steam vessel accidents, he ascertained that of twenty-three explosions, nineteen occurred on the instant of starting the engines, or whilst the vessels were stationary; three only whilst the engines were at work: the greatest number took place at the moment of admitting the steam upon the piston. He attributed this effect to the steam's percussive force, which would be as much felt by the boiler as by the piston; if the boiler was weak, and, distended by steam to nearly the bursting point, the shock would be sufficient to cause its rupture. Mr. Parkes then gave several instances of such occurrences.

Steam Vessel explosion at Norwich.—In 1817, the boiler of a steam vessel at Norwich burst, and killed many persons. Previous to the accident, the boiler leaked in several places; the steam issued copiously from the safety valve, which was evidently very heavily loaded. The engine had scarcely made a revolution before the explosion occurred. By applying the present state of our knowledge to these facts, he felt assured that the steam's impact on the piston had been the immediate cause of that accident.

Explosion at Passy.—In 1826 or 1827, Mr. Parkes witnessed the effects of an explosion, a few minutes after its occurrence, in the neighbourhood of his [illegible], near Paris. The boiler was of wrought iron, [illegible] feet 6 inches, or 3 feet diameter. By his advice the [illegible] put in a new end, formed of one piece of hammered iron, and [illegible] dissuaded from overloading his engine, or using [illegible] pressures. The cylinder of the engine was horizontal, and was connected with the boiler by a short pipe and cock. The proprietor informed him, that finding his machinery working too slowly, he went into the engine-house and stopped the engine. He held down the lever of the safety valve, and on turning the cock to start the engine, the explosion instantly occurred. The new end of the boiler, which was opposite to the engine, was found separated from the body, and lying in the flue. The line of rivets and a complete ring of the new end remained upon the body, apparently little forced, and the faces of the fractured ends were as sharp and clean as if cut by a chisel or shears. The boiler, engine, and masonry, were driven into the yard in the opposite direction to the escape of the water and steam; thus, though the entire end of the boiler was removed, and the whole contents evacuated, it acted too late as a safety valve.

Explosion at Camden Town.—He observed similar effects last year in an explosion at Camden Town, being fortunately on the ground to investigate it before much change had been made. Two boilers were set end to end with a chimney between them. The end of one was blown out, and was lying close to its original seat. It was forced backwards into the chimney, which it partly supported on a pipe flange, and pushed the other boiler and entire masonry in a horizontal direction fully two feet. He considered that the percussion of the steam from its re-action against the opposite ends of the boiler in the act of tearing it off (which was the effect in this case) produced the recoil. In this case there were upon the boilers (which were connected together) two safety valves in good order, and not heavily loaded. The accident occurred during the breakfast hour, whilst the engines were not at work. One of the two stays which originally held the fractured end of the boiler, was found to have been previously broken, as its separated ends were covered with old lime-scale—the other had evidently been long cracked, and was only held by a fragment. The fractured end of the boiler was not exposed to the fire, nor did the shell or the flue within it exhibit any marks of injury from fire or from dislodgment of scale. The steam, in its effort to escape, acting first against one end, not only raised the boiler from its horizontal position to an angle of about 45°, but gave it a twist obliquely from the line of its bed.

High and low pressure.—Mr. Parkes could not agree in the often expressed opinion, that what are called high-pressure steam boilers were more dangerous or more liable to explode than others. Much depended on care and management. He believed that he was in possession of accounts of nearly all the explosions which had occurred in Cornwall since the expiration of Mr. Watt's patent, when higher pressures began to be used, and they amounted only to five or six instances, exclusive of some cases of collapsed flues. More explosions had occurred in a small district round Wednesbury during the present year with low pressure boilers, than in Cornwall in forty years, where the highest pressures were employed. He believed also that the coal districts of Northumberland, Durham, and Staffordshire, would furnish more cases of these disasters from boilers both of high and low pressure, than all the rest of England put together.

The coal districts.—When the practice in the coal districts was contrasted with that of Cornwall, the explanation was simple. Where coal was so cheap, the quantity used was unlimited, the negligence was great, and the allowance of boiler was small for any given sized engine, as enough steam could be raised by fires of greater intensity—the rule there being, to save in the first cost of the boiler; in Cornwall, on the contrary, the object was to insure economy in the consumption of fuel; consequently, all that class of accidents arising from injury to plates by fire and deposit, would be in about the ratio of the intensity of the combustion.

Notwithstanding the bad practice generally prevailing in the coal districts, there were some exceptions. At an iron work near Dudley, there were boilers now in good order after nearly thirty years' use, having required but trifling repairs during that period. In those boilers the plates of the bottoms which were exposed to the fire were all made of hammered, not of rolled iron—the boilers were large for their work, and were cleaned thoroughly every week.

Hammered plates.—Tilted plates were alone used for salt pans in those parts where the heat was most intense. Though continually heated to redness, and distorted by the action of the fire, the quality of the iron in plates thus formed did not appear to be deteriorated, for when taken out the smiths used them for making rivets, nails, &c. Rolled iron plates would do for making coarse salt, which required a heat below ebullition, but they were quickly injured when used for fine salt, and were useless when taken out.

Explosion at Essonne.—Mr. Parkes then adverted to several other remarkable cases of explosion. It was a well authenticated fact, that a boiler belonging to Messrs. Ferey, at Essonne in France, exploded on the instant of opening the safety valve.

Explosion at Lyons.—Three successive reports were heard when [illegible] steam boat boilers exploded at Lyons, indicating that [illegible] at the same instant. Now, though Mr. [illegible] had [illegible] valve to increase the pressure of the steam, [illegible] should, according to the received opinion, [illegible] second and third, and have saved [illegible] boiler, the pipes would be [illegible] [illegible] instances of successive explosions had occurred in England. He would not at present enter upon an explanation of what he considered might have occasioned these phenomena, but he would express his conviction that the practice of suddenly opening and closing the safety valves was extremely dangerous. To be useful as escape valves, they should be allowed to open and to close in obedience to the steam's pressure only, not to be handled more than was absolutely necessary.

None of the theories yet advanced appeared clearly explanatory of the cause of the projection of heavy boilers from their seats, when in many cases they contained abundance of water. He instanced a case in which a boiler exploded, and carried to some distance a boiler connected with it, and in which some men were at work. The boilers separated while in the air, and the one which exploded attained a very considerable height, although it was 28 feet long by 6 feet diameter. The particulars of this explosion were furnished to him by Mr. Clarke, engineer to the Earl of Durham, but they could not be properly appreciated or explained without the drawings and description.

Explosion at Durham.—A boiler weighing about 2½ tons was projected from its seat at Messrs. Henderson's Woollen Factory at Durham, in 1835; it ascended to a considerable height, and fell 300 yards from the place where it had been seated.

Crenver Mine.—A cylindrical boiler exploded at the Crenver Mine in Cornwall in 1812. It passed through the boiler house, and opened itself in the yard outside, where it was described to have fallen "as flat as a piece of paper."

Facts of this nature were replete with interest, and should lead engineers to the consideration of causes and remedies.

Boilers red hot.—Mr. Parkes then instanced several cases of boilers which had become red hot, and had not exploded; one example was a set of three boilers, the tops as well as the bottoms of which were red hot, in consequence of the house in which they were fixed being on fire; yet they did not explode. No water had, however, been pumped into the boilers whilst so heated.

Explosions of hydrogen gas.—He was in possession also of several curious examples of ruptures and projections of vessels arising from causes very different to the foregoing. One case occurred in February 1837, at the Works of Messrs. Samuel Stocks and Son, in the Township of Heaton Norris, near Manchester. The boiler was 20 feet long, 9 feet wide, and 10 feet deep, and weighed about 8 tons. On a Saturday night the water was blown out of it through the plug-hole at the bottom, by the pressure of the steam, the man-lid not being removed. On Sunday evening the fireman proceeded to take off the man-hole cover to clean the boiler; on entering it with a candle and lanthorn, a violent explosion occurred; and the man was projected to some distance and killed. On examining the boiler it was found quite dry, no fire being alight, no traces of water near it, and it was quite cold: it had been lifted from its seat up to the roof, which it destroyed, and the walls of the building were thrown down. There was no difficulty in accounting for the presence of a combustible gas, as hydrogen might be evolved from the decomposition of the steam (which would remain in the boiler after the expulsion of the water) by the heated sides and bed of the boiler, and the atmospheric air which entered through the plug-hole or through the man-hole, when the lid was removed, was sufficient to form an explosive mixture. The projection of the man was the simple effect of firing the gas; but to account for the entire boiler being carried from its seat, was more difficult. The figure of the boiler after explosion exhibited two distinct actions; the ends and sides had evidently been bulged outwards by the force of the explosion within it, and the bottom had been crushed upwards by the force which raised it from its seat.

Mr. Parkes thought the circumstances admitted of a satisfactory explanation, but would not then enter upon it, as it involved the history and phenomena of projections of vessels from their beds with a vacuum within them, which he thought would be better understood after the reading of his paper on the "Percussive Force of Steam and other Aeriform Fluids," then in preparation for the Institution.

The foregoing case of the formation of hydrogen gas in a boiler, after all the water had been evacuated, was confirmed by one which took place in a similar manner at the Sugar-house of Messrs. Rhodes and Son, in London, of which all the particulars had been furnished to him by Mr. Henrickson, the manager. A man entering the boiler with a candle and lanthorn to clean it, was projected to a great height. No rupture of the boiler took place, as the quantity of hydrogen seemed to be comparatively small, and to be confined to the upper portion of the boiler, but a series of detonations occurred, like successive discharges of cannon.

These two remarkable instances showed the importance of attending to minute circumstances in the management of boilers. The practice of completely blowing out boilers whilst the flues were intensely heated, was evidently dangerous, nor should it be done without removing the man-hole cover.

Mr. Parkes felt that these notices of explosions were very imperfect without drawings, and reference to documentary evidence, but, as the subject had been brought before the Institution by Dr. Schafhaeutl, he hoped that they would be received as contributions to the stock of knowledge, and as illustrative of the precautions to be observed by attendants on steam engines.

Mr. Seaward was glad to find the idea of the explosions of boilers arising from the formation of hydrogen gas, so successfully combated by Dr. Schafhaeutl and Mr. Parkes. He perfectly agreed with the former in his opinion of the causes of the majority of explosions. In all that he had witnessed the effects of, the lower parts of the boiler appeared to have suffered most.

He was at the Polgooth Mine immediately after the explosion there, when seventeen persons were killed. In that case, he was told that the boilers were moved a distance of 7 or 8 feet from their seats, before any detonation was heard.

At the Hurlam Mine (which Trevithick had undertaken to drain for a certain sum) an engine with a cylinder of 40 inches diameter was erected immediately over the shaft. Its power was not sufficient for the work required; the pressure of steam was therefore gradually increased as the depth became greater. At length the boiler, which was of an immense length, was observed to have a constant tremulous or sinuous motion at each stroke of the engine, and eventually it exploded.

Boilers in London.—It appeared that there were fewer explosions of boilers in London, in proportion to the number employed, than in any other district. One reason for this might be, that fuel being expensive, it was used economically, by maintaining a slow rate of combustion, and a regular supply of steam, avoiding the intense action of the fire, which, in the event of the engine standing still for a time, had a tendency to produce an explosion.

Mr. Parkes attributed the small number of explosions of boilers in the vessels on the Thames to the practice of allowing the steam to act upon the safety valve, instead of the engineer lifting it when the engine was stopped, as on board vessels in the north. The sudden closing of the valve had in many cases produced an explosion.

While on this subject, he felt it necessary to comment upon what he considered fallacious reasoning of Tredgold on the formation of hydrogen gas in boilers.* The passage he alluded to was couched thus:—"Hydrogen gas may be, and frequently is, formed in steam boilers through the water being in contact with a part of the boiler which is red hot; and it seems to be regularly produced during the formation of steam at very high temperatures." Dr. Schafhaeutl had shown, that the effect of water coming suddenly in contact with a part of the boiler which was red hot, was only to disengage instantaneously a large volume of steam of very high elasticity. Mr. Parkes contended, that an instance of the sudden production of hydrogen gas in a boiler under such circumstances was unknown, and he much doubted the possibility of such an occurrence. Again, allowing such an event to be possible, an explosive mixture of gases must be formed before the boiler could be destroyed; and this could not take place so long as a sufficiency of water was present, from which any considerable quantity of steam could be generated.

Mr. Donkin did not entirely agree as to the non-formation of hydrogen in boilers under peculiar circumstances. He conceived the explosions which occurred in iron founderies, on the contact of the melted metal with wet sand, to be analogous. He believed, that when water was thrown suddenly upon red-hot plates, decomposition did occur.

He had once examined a wagon-shaped boiler which had exploded; the top was thrown to some distance, and the bottom was depressed throughout its entire length. He believed, that by intense firing the water had been nearly all evaporated; the bottom had then become red hot, the pressure of the steam had forced the bottom downwards when weakened by the heat; the water on each side then suddenly flowed on to the heated part, and an explosion instantly occurred.

Mr. Seaward had known instances of the internal tube of a boiler being collapsed without any injury to the external part or body of the boiler. He had always ascribed such occurrences to a deficiency of water; but Dr. Schafhaeutl's explanation of the rapid transmission of force through the wave to the bottom would sufficiently account for the effects which had been observed.

Mr. Donkin believed, that in almost every case the unequal pressure upon the exterior of the tube, arising from its not being perfectly cylindrical, was the cause of its collapsing.

Mr. Field was inclined to attribute all the explosions which he had witnessed to simple pressure.

When steam, or a small quantity of water, was suddenly admitted into a dry heated vessel, hydrogen gas was readily formed. He had made several sets of apparatus for the purpose. A strong wrought-iron tube was heated, and, being filled loosely with fragments of iron-turnings, steam was introduced and the gas was rapidly evolved.

He agreed with Mr. Parkes in condemning, generally, the fallacy of the opinion of Tredgold, previously mentioned, as to the formation of hydrogen gas. Still, in a large boiler, almost dry, and of which a portion was red hot, he conceived, that on the admission of a small quantity of water, hydrogen gas might be evolved.

Elevation of boilers from their seats.—The President was unwilling that this conversation should terminate without endeavouring to explain the cause of the elevation of the boilers from their seats. In his opinion, this might be satisfactorily accounted for by the action of atmospheric pressure.

When an explosion took place in a boiler, a considerable body of highly elastic fluid was disengaged; a partial vacuum was thus created above the boiler, whilst the full pressure of the atmosphere was exerted beneath it. This would cause the boiler to rise from its seat, provided the atmospheric air did not at the same instant rush into it, in which case the bottom would be pressed downwards, and the upper part being torn asunder, as had been described, would then rise into the air with the elastic fluid.

* Tredgold on the Steam Engine, vol. i. p. 251. Edition by Woolhouse.

When it was considered that the superficial area of these boilers was about 60 square feet; that the pressure of the atmosphere was nearly 1 ton per square foot, and that the weight of the boilers was only 8 or 10 tons, it would be apparent that the cause was quite adequate to the effect, with a very partial vacuum or inequality of atmospheric pressure. The case was analogous to those in which light bodies were raised into the air by whirlwinds.

He referred also to two cases of an equally uncommon nature, which had lately come under his notice professionally, and which he considered to arise chiefly from inequality of atmospheric pressure.

The first occurred at the Plymouth Breakwater during the great storm in the month of February, 1838, when several of the largest granite blocks, weighing from 3 to 8 tons each, composing the surface or pavement of the breakwater, which, although squared and dove-tailed into the structure, and embedded in excellent cement to the extent of their whole depth, and thus forming a solid mass, were torn from their positions, and projected over the breakwater into the Sound. He attributed this to the hydrostatic pressure exerted beneath the stones, at the moment when the atmospheric pressure above had been disturbed by the masses of water suddenly and rapidly thrown upon the surface of the breakwater. Blocks of stone were thus often carried to a great distance, not so much by the waves lifting them, as by the vacuum created above them by the motion of the water, which exerted at the same time its full pressure from below.

The other case occurred during a storm in the year 1840, when the sea door of the Eddystone Lighthouse was forced outwards, and it strong iron bolts and hinges broken by the atmospheric pressure from within. In this instances he conceived that the sweep of the vast body of water in motion round the lighthouse had created a partial and momentary, though effectual, vacuum, and thus enabled the atmospheric pressure within the building to act upon the only yielding part of the structure.

Signals for Railways.

A letter was read from Mr. Edward Alfred Cowper, describing some experiments on the use of maroons as signals on railways.

The maroons are either small tin cases, or cartridges of brown paper, charged with from ½ oz. to 2 oz. of gunpowder, mingled with which are 4 of "Jones's Prometheans," which are small glass tubes, each containing a drop of sulphuric acid; the tubes are surrounded with chlorate (hyper-oxy-muriate) of potassa, and are each enveloped in a strip of paper.

In the event of an accident occurring, which renders it necessary to give notice that an approaching train should be stopped at a given point, two or more of these maroons are fastened upon the upper surface of the rail by the strips of lead attached to them. The wheels of the engine, in passing over them, crush the glass tubes of the "Prometheans," the sulphuric acid inflames the chlorate of potassa, and causes an explosion of the gunpowder, which is distinctly heard by the engine driver, who immediately shuts off the steam, and puts down the break.

Mr. C. H. Gregory had permitted several trials to be made with these maroons on the Croydon Railway.

An engine was driven at full speed with a number of empty wagons attached to it, and with the steam blowing off to create as much noise as possible, yet the explosion of even half a drachm of gunpowder was distinctly perceived: he considered the invention to be practically useful.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

ELEVENTH MEETING, 1841.

Description of the existing and contemplated Railways and Machinery connected with the Granite Quarry on Dartmoor, and of the mode of working them. By William Johnson, Grosvenor Wharf, Westminster.

Dartmoor is an extensive granitic table-land occupying the heart of the county of Devon, and in which many of the rivers of this county originate. It is in length from north to south 22 miles, and in breadth from east to 14 miles. The height of the table-land above the level of the sea is from 1000 to 1200 feet; but the surface is broken by numerous masses of rock, which run up to three, four, and five hundred feet above the ordinary level of the moor; these are ranged in short chains, or they rise in rifted blocks, or in insulated hillocks, which are distinguished as Tors, or provincially *Tars*.

The surface granite of Dartmoor, which is in detached blocks, in infinite quantity, had been employed in the neighbourhood for the ordinary purposes of building from time immemorial. Quarried granite from Dartmoor was first brought into the market about 1820 by the Haytor Granite Company. A stone tramway was constructed from the Haytor quarries on the south-eastern face of the moor to the Stover Canal, near Newton Bushel, a few miles above Teignmouth, the nearest available port at which stone could be shipped, and by this means Dartmoor granite came into the market at considerable advantage, especially as the quality of the stone is such as to enable it to compete with the best Aberdeenshire, and, for many purposes, the lightness of its tint aided by the fineness of its texture, and the almost un-ed size of the blocks in which it could be procured without defect secured it a preference. The western face of London Bridge is mainly composed of granite from Dartmoor. Dartmoor granite has also been introduced into many of the public buildings in the metropolis; amongst others the New Post Office, the Goldsmith's Hall, Fishmonger's Hall and Buckingham Palace.

The establishment of the Plymouth and Dartmoor Railway, which was completed in the year 1825, directed attention to the fine granite on the western face of the moor, by affording ready means of transport to the port of Plymouth for stone from Foggintor and other points adjacent.

The length of the Plymouth and Darmoor Railway, from Prince-town to the Tide Docks, known as Sutton Pool, at Plymouth, is about 25 miles; though the distance from one terminus to the other, by the carriage road, is not more than 16 miles; whilst a right line, from point to point, does not exceed 13 miles in length, the greater length of the railway being occasioned by windings to save expensive works, and to obtain tolerably equable inclinations upon which the trains might run down freely and allow the empty or slightly laden waggons to be drawn back without much waste of power.

The whole rise of the railway from its toll-house in Plymouth to the Prince-town terminus, by the Prisons of War, is 1350 feet; which, upon the net distance of 24 miles between those points, gives a rise of 56·25 feet per mile, or a ratio of nearly 1 in 94. The road is almost entirely upon the surface, with occasional slight cutting and filling, and a short tunnel (30 chains in length) occurs within the fourth mile from Plymouth. The wagons or trucks used upon the line consist of a platform or bed, set upon two centres, on two under carriages, to adapt them to their work and to the excessively sharp curves and irregular surfaces that frequently occur upon the line. The power used in working the line is the gravitation of the load, assisted by horses, the return being by horses entirely. Three horses draw eight single wagons, or four double ones, with from 30 to 40 tons of granite down, and take the wagons back when empty. There are at present no planes upon the line having gear worked by fixed power, or as self-acting planes.

The quarry which affords this railway its principal occupation, is worked by the Haytor Granite Company. It is situated within a quarter of a mile of the main line of the railway, from which a branch is laid into the quarry, at two miles from Prince-town, the floor of the quarry being at a level of 48 feet above the turn-out, and 1260 feet above the level of the quay at Plymouth, from which the stone is shipped.

The quarry is on the side of the Mount known as Foggintor, at from 350 to 400 feet below the summit. A gullet was first driven in horizontally, until a face of rock 50 feet high was obtained, presenting a most beautiful section of stone, in beds or layers of from eight to ten feet thick. The gullet has since been carried forward from 110 to 120 yards, and extended laterally until the bed of the quarry presents a cleared horizontal surface of nearly 4000 square yards. The benching onwards and outwards of the upper layers exceeds 2600 square yards, and the highest bench is 80 feet above the rails on the floor of the quarry. A considerable further extent of surface, beyond and above this, is uncovered of earth, and, the crust being removed, a vertical section of the granite tor is exposed, of nearly 100 feet in height.

A single blast in this quarry has been known to separate and remove 3000 tons of stone, and single blocks have been sent out weighing 20 tons, computed to contain about 250 cubic feet.

From the lower benches, in the face of the quarry, the stone has been taken up by derricks, or moveable cranes, and placed by them in the usual manner upon trucks on the railways, laid on the floor of the quarry; whilst, from the topmost benches, the stone is delivered over the side of the hill, and skidded down an inclined plane to the masons' sheds, where the operations of converting and dressing are performed, and from whence the blocks are conveyed upon railway trucks to the place of shipment.

The existing facilities for working the quarries, are now in course of further extension, by the construction of strong timber stages or scaffolds, with travelling frames, and upon the frames powerful traversing crabs, avoiding thereby the excessive labour and delay of lifting by the ordinary means of derricks and cranes. These stages rest upon the floor of the quarry in front, and run in parallel lines of 30 feet in width onwards upon the benches according to their heights, and give the means of taking up the stone wherever the blocks may be thrown out in blasting upon the different benches, and placing them at once upon the trucks on the floor of the quarry, by which they are taken to the mason's sheds, so that the quarry is kept constantly clear, and the largest blocks of stone are moved out with the greatest possible ease. An arrangement is in progress for transferring the travelling frames, with the crabs upon them, from one line of scaffold to another, by which means power may be accumulated to almost any extent upon any one stage, to operate upon blocks of extraordinary size.

Foggintor granite is at present extensively used for all the purposes to which granite has been hitherto applied. It is superior to any other in this country for steps, plinths, string and blocking courses, ashlars, pedestals, obelisks, columns, cornices, and indeed for all the purposes of architecture, because of the freedom and comparative ease with which it can be worked, being alike capable of the finest arris and of the fairest face, whether moulded or plain; whilst the purity and evenness of its colour, and the fineness of its texture in the deep beds, give it advantages not possessed in an equal degree by the produce of any other quarry in Great Britain. Foggintor granite is moreover peculiarly fitted for the more massive works of the hydraulic architect or engineer, on account of the magnitude of the blocks in which it procurable. It is in great demand for the quoin, hinge, and dock and other lock gates, for altars in graving docks, as w floors and curbs of such massive constructions, and for bridge constructions in all their varieties. Indeed, notwithstanding the facilities with which the work in the quarry is performed, the extent and depth of face exposed, and the ease with which the blocks are got out of the quarry, and upon the railway, it has hitherto been found difficult to supply, with sufficient rapidity, the existing demand.

The works at the Government Yard at Devonport—those of the magnificent new graving dock now in course of construction at Woolwich—Tenby Beacon in Pembrokeshire—the Neale Memorial in the New Forest, Hants—and the Nelson Testimonial—the retaining walls of Trafalgar Square—and the new buildings of the Sun and Alliance Fire Offices, in London, are all supplied with granite from the Foggintor Quarry. Many private works in various parts of England are also supplied with granite from this quarry, and the terrace walls and their approaches in the great quadrangle of Christ Church, Oxford, are about to be restored with Foggintor granite. Indeed, the fine texture and tint of Dartmoor granite adapt it peculiarly for terraces and for the basements of buildings whose superstructure and other collateral works are of Portland stone, Bath stone, or any of the best English free-stones.

An important feature in the quarry now under consideration is the great depth at which the beds already accessible lie below the surface, yielding therefrom stone of the greatest degree of compactness and strength with perfect equality of colour; whilst the horizontal disposition of the rock allows of the removal of stone of fair forms, and in blocks of the largest size. Blocks have been sent from the quarries on Dartmoor even to Scotland to supply works there with sizes which could not be procured in that country. Sir Francis Chantrey's bronze statue of King George the 4th, in Edinburgh, stands on a block of Haytor granite, and the statue of Watt, at Glasgow, by the same distinguished sculptor, is also placed on a block of granite from Dartmoor.

Mr. Rendel bore testimony to the excellence of the quality of the Dartmoor granite, and to its peculiar fitness for any kind of work. The material was extremely good, and of sufficient fineness to admit of the most delicate moulds being made for it. It cleaves freely; there is little waste, and pieces of stone of all sizes, from the smallest to the largest, can be readily obtained. He had, some time ago, taken the dimensions of a block, and found it to be 67 feet in length, 5 feet by 8 feet at one end, and 3 feet by 5 feet at the other end. If a great outlay were justified, this granite would be the cheapest stone that could be used. The President stated, that he had attempted, some years ago, to introduce this granite into the market by means of the canal, near Tavistock, and now that such facilities existed for its transport, he would direct public attention to the beautiful slabs, columns, vases, and forms into which the Aberdeen granite was worked, and express his hopes that before the British Association next met at Plymouth, there would be a large manufactory of these articles in Dartmoor granite. The beautiful porphyry of Cornwall might also be employed in a similar manner. He could mention a remarkable instance of the durability of the Dartmoor granite. A slab which had been used as a foot bridge from time immemorial had recently been removed, and on the face, which had been turned downwards, was a Roman inscription, showing it to be at least 2000 years old.—Mr. Eaton Hodgkinson, in reference to some questions which had been asked, respecting the strength of stone according to the position in which it was placed, stated that in all bodies of uniform texture the strength would be the same in whatever position they are placed, but in bodies that are laminated the case is very different. He observed a very pernicious practice to have prevailed in the construction of many of our buildings, namely, the placing the stone without any regard to the direction of its lamination. He had extended his experiments to a great variety of stone, and he found that cubes of granite when broken with the greatest care, break up at once into wedges. Some valuable experiments on the strength of granite were published in the Transactions of the Institution of Civil Engineers, but the mode in which the experiments had been conducted was not stated, and a distinction is drawn between the crushing and the breaking force; but he thought that if the experiments had been made by pressing the stone between two perfectly smooth plates a somewhat different result would have been found; the granite would have broken up at once without crushing, as was uniformly the case in his experiments. He thought it important to interpose a thin substance, as a sheet of paper, between the plate and the stone; the pressure by this means becomes more perfectly distributed. A remarkable connexion existed between the ratio of the forces of extension and compression, and the angles at which the wedges or masses would slide off when broken by pressure. If these forces were equal, the wedges would slide at an angle of 45°.—Prof. Moseley remarked that the experiments of Mr. E. Hodgkinson were peculiarly valuable, because he had not confined himself to cubes, but extended his experiments to other forms. A singular prejudice had existed in favour of cubes. The commissioners appointed to report on the stone for building the House of Commons, experimented simply on cubes, whereas rectangles would have been much better.

Dr. Lardner's *Report on Railway Constants* was read. Details of this paper were presented to the Association in the year 1839, and reported very fully in the *Journal*, vol. 2, page 383, but as the communication was then merely verbal, and the rules of the Association require a written report, the report was formally presented, and the reading led to a good deal of discussion, but no new facts were elicited.

"*Report of the Committee on Railway Constants.*" By Edward Woods.

In a preceding Report of the Committee (published in the 8th volume of the Transactions of the British Association), five various modes of ascertaining the resistance to the tractive power on railways were described, and their relative merits discussed, and a variety of experiments on one of these methods, viz., by observing the motion of a load down an incline, sufficiently steep to give accelerated motion, having been made, it appeared, that the resistance increased in a degree previously unsuspected in proportion as the speed of the train increased,—but in what ratio, was not then determined, owing to certain discrepancies due, principally, to the varying effect of the wind at the time of the experiments. The Committee have continued to conduct their experiments in a similar manner, repeating them with various sizes of trains, at various velocities, on the Sutton incline, of 1 in 89 on the Liverpool and Manchester Railway, and on the inclines of 1 in 177, 1 in 265, and 1 in 330 on the Grand Junction Railway.* The data ascertained and given in the Report are,—1, The co-efficient of gravity on the inclination of the plane. 2, The initial velocity of train at some determinate point on that plane. 3, The terminal velocity at some other determinate point on the same plane. 4, The time elapsed in traversing the space intervening between these two points. 5, The space intervening. 6, The force of gravitation. 7, The weight or mass of the train, exclusive of the wheels and axles. 8, The weight or mass of the train subject to the rolling motion, viz., the wheels and axles. 9, The radius of the wheels. 10, The distance from the centre of the wheel, to the centre of oscillation. If a body move down an inclined plane without resistance, its velocity at any given depth below the level of the point where its motion first commences, will be equal to the velocity it would have acquired by a free vertical descent through the same height. This standard velocity being compared with the observed velocity of a body moving down an incline, and meeting with resistance, the amount of that resistance can be assigned. This mode has been objected to, from the apparent inconsistencies in the results; but these may be readily explained; and the Report shows a remarkable correspondence in the motions of the same train, when permitted to descend the same plane from the same point, provided the atmosphere be perfectly calm. The usual formula is applicable to three cases of accelerated, uniform, and retarded motion; the co-efficient of gravity is greater than, equal to, and less than the co-efficient of resistance accordingly; and the requisite correction will be negative, zero, and positive, so that the co-efficient of resistance may be found in all cases. The method of determining this correction was set forth in the former Report. When the motion is uniform, the mean resistance for any particular velocity may be assigned; but when the motion is accelerated or retarded between the two points of observation, although the mean resistance may be known, it cannot be stated with accuracy, whether that mean resistance is due to the mean velocity, or to some other velocity intermediate between the limits of the initial and terminal velocities, because experience has not yet assigned the law of the corresponding increments of resistance and speed. The results which the tables of this Report present, are considered under the following heads: the determination of the friction; the additional resistance produced by increase of speed in trains of different sizes; the effect of modifying the form of the front or end of carriages, and of other changes in the external surface of the train. Three first-class carriages were allowed to descend the Sutton incline from rest four times in succession, a length of 2420 yards. It appears that the resistance diminishes until the train attains the speed of 7·58 miles per hour, after which it increases: at 4·32 miles per hour, the resistance was 6·07 lb. per ton; at 7·58 miles per hour, 5·6 lb. per ton. This remarkable and hitherto unobserved result is owing, probably, to the more perfect lubrication of the axles at the higher speed; a certain thickness or film of grease is formed between the brass step and the upper surface of the journal, and keeps the two surfaces more effectually apart; at the lower velocities, the pressure of the step upon the journal has a longer time to act in effecting the displacement of the fresh grease which has been supplied from the box, and the result is, a greater amount of friction. Eight second-class carriages were allowed to descend the Sutton incline; the friction was a minimum at 5·81 miles per hour. The following results may be deduced from the above-mentioned series of experiments. 1, The friction was least when the train was moving at the rate of about 6 miles per hour. 2. The total resistance was also least at the rate of about 6 miles per hour, notwithstanding the effect of the atmosphere at that speed. 3, The mean resistance of first-class carriages was never less than 5·6 lb. per ton; and of the second-class never less than 7·75 lb. per ton; 6 and 8 lb. per ton will represent very nearly the mean of the resistances; and these values are used in the subsequent part of the Report. The motion of these trains being observed at lower parts of the incline, where the velocities were greater than the preceding, the resistance to the train of three carriages was 8, 12, and 16 lb. per ton, at velocities of 22, 26, and 29, miles per hour respectively, and the resistance to the train of eight carriages was 11, 12, and 14½ lb. per ton, at the velocities of 20, 25, and 29 miles per hour. Trains of 4 and of 6 carriages were impelled to the summit of the incline, and, the engine being detached, commenced their descent at the rate of 33 and 26 miles per hour. They descended through the first half of the incline with a mean velocity of 34 and 29 miles per hour, and through the latter half, with a mean velocity of 37 and 33 miles per hour. Other series of ex-

* As Dr. Lardner's paper on "the Resistance of Air to Railway Trains," (read at Newcastle, and reported fully, with diagrams, Journal, vol. 2, p. 383, was founded on these experiments, the reader had better refer to it.

periments were made on the Grand Junction inclines; and the result of the whole shows the existence of an opposing power, created as it were by the speed itself, far exceeding that hitherto suspected.

A train of eight carriages weighing 40½ tons was started down the Madely incline 1 in 177, at speeds varying from 23 to 26 miles per hour; the mean speed attained was 25¼ miles per hour. The motion of the train became uniform, so that the coefficients of gravity and resistance were equal. The mean resistance of the train was 12¾ lb. per ton. A train of four carriages was started down the incline at 40 miles per hour, half way down the plane the velocity was reduced to 30 miles per hour, and at the foot, it was only 25 miles per hour. Four other carriages were started at a velocity of 32·7 miles per hour, they were retarded to 22·7 miles per hour, and proceeded with this uniform velocity to the foot of the incline. The results obtained in these experiments with the trains of eight carriages are of great practical importance, this being the nearest approach to the average passenger trains. 30 miles per hour is a fair average speed, and the resistance at the speed is about 15 lb. per ton, or almost double the value of the friction only. The friction may be diminished by proper attention to the fittings and the perfect lubrication of the axles, but its reduction is of secondary importance in the economic working of passenger trains, which, from their high velocity, must necessarily bring into play large and independent sources of resistance. The resistance to trains at different speeds being ascertained, the Committee directed their attention to the effect of external configuration on the resistance. A pointed body, as a prow, was fixed successively to the front and end of a train, but the differences observed were extremely slight, and such only as would have occurred with the same experiment repeated twice over; the pointed figure, whether before or behind, exercised no appreciable influence on the rate of the train's motion, or on the resistance of which that motion is the index. Experiments were also instituted, to ascertain whether the carriages being sent with their square ends forward, instead of being preceded by an engine and tender, would affect the results, but here also there were no greater differences than might be expected in an experiment repeated twice over; and it may be fairly concluded, that the form of the front has no observable effect, and that whether the engine and tender be in front, or two carriages of equal weight, the resistance will be the same. The intermediate spaces between the carriages were closed in, by stretching strong canvas from carriage to carriage, thus converting the whole train into one unbroken mass. The results were in favour of the train without canvas, but the differences are extremely slight; it is certain that no additional resistance is occasioned by leaving open spaces between the carriages, confining the intervals to the dimensions allowed in practice.

The Committee having ascertained that the excess of resistance, after deducting friction, required for its estimation something besides the elements of the dimensions and form of frontage, and of continuity of surface, it becomes important to inquire, what is the element exerting so powerful an

Their former Report contains the results of experiments with on the Madely incline loaded to six tons each, and furnished with boarded fronts and sides moveable at pleasure: the differences in the results attained, were then referred to the increased frontage alone. But the experiments detailed in the present Report having been made, it became probable that the increased resistance was in a great measure dependent on the general volume of air displaced; and the Committee recommend experiments to be directed, to ascertain the effect on the resistance of diminishing and increasing the bulk of trains, the weight remaining the same.

were also made with the view of determining the amount of moving power expended in working a line, and for this purpose, the character of the line, in respect of its inclines, the weight and bulk of the train, and the speed at which the load is required to be conveyed, must be considered. The first of these alone is constant, depending on the nature of the acclivities and declivities. As an abstract question of dynamics, the power expended (the resistances being supposed constant, whatever the speed) is the same for a train travelling between two points on the same level, whether the road be be level or undulating, a due allowance being made for the difference of distance traversed. On the level line of railway, the speed of travelling would be uniform, but on the undulating line it would vary. And the real question is, will the increased velocity on the declivities compensate for time lost on the acclivities? Will the average rate of speed over the whole line be different? In order to obtain some definite result on the point, it was determined to send a train from Liverpool to Birmingham and back, a distance of 190 miles. Great care was taken in conducting this experiment, and the results are tabulated in great detail; and the following remarkable inference may be drawn, that a train of 12 carriages drawn by the same engine can be conveyed over a railway whose gradients range within the specified limits, in the same time as it could over a perfectly level railway of the same length. In ordinary practice, an engine of the dimensions tried (the Hecla) would receive assistance up the Sutton, Whiston, and Warrington inclines (1 in 89, 96, and 80), but this was not the case in the experimental trip, and the train encountered acclivities and declivities not contemplated in the application of this theory. It may therefore be inferred that the opinion entertained was correct, or that trains whose weights bear an ascertainable relation to the nature of the inclines they have to traverse, may be made to traverse those inclines at an average speed equal to what the power of the engine can effect on a level, and that an ordinary train would travel over the Grand Junction Railway (the steeper inclines of 1 in 96 being excepted) in as short a time as if the line had been absolutely level.

Mr. Brunel remarked on the inapplicability of results obtained from trains running down inclines to the ordinary working of trains on railways. Many of the results given in the Report differ exceedingly from the results of his experience in the working of the Great Western Railway. The cause of this discrepancy arose from the manner in which the resistances were obtained. In the train of carriages running down an incline, each carriage is slightly pressed upon by the next behind, so that the whole train is in the condition of a train that is pushed; and it is well known that the resistance of a train pushed from behind is much greater than of the same train pulled from before, as the carriages are thrown out

"*Remarks on the Connexion which exists between Improvements in Pitwork and the Duty of Steam-engines in Cornwall.*" By Mr. Enys.

After adverting to the admission of the truth of progressive increase of duty, it was shown that considerable changes have been made in the course of seventy years, in the methods by which water is lifted out of the mines in Cornwall; and that in comparing the duty of earlier periods, an allowance of the difference of the Imperial and Winchester bushel of coal ought to be made. The distinction between horse-power and duty, pointed out by Mr. Parkes, was alluded to; one excludes, the other includes, the friction of the pitwork; and the remarks attached to each in Lean's report, show the necessity of adverting to the different conditions of the pitwork, in an attempt to estimate with accuracy the relative merit of different engines separate from the pitwork. In an endeavour, some time ago, to trace the causes of the great variation of the duty, a small amount of expansion was observed in engines remarkable for a low duty, and the reasons assigned were, either weak pitwork—flat rods—heavy load per square inch on the piston, and old boilers—and often the joint action of the above causes. The strength of the pitwork, or of the boilers, in different cases, seems to become the limit of expansion in the engines. In reference to deficiency of water from pumps, in proportion to the calculated quantities, on which duty is founded, two causes have operated in inducing a strong belief that it is less than at any former period: 1. Greater attention to the pitwork by the managers of the mines, under whose care it is placed, to the exclusion of the engineers of the steam-engine by which it is worked; 2. The extended use of the plunger pump—the latter instantly showing the slightest defect of the packing, and allowing of an easy remedy; while the bucket pump, on the contrary, does not show the defects in the packing: and the operation of tightening it is attended with great difficulty, so much so, as often to cause the repairing to delayed to the last moment that the pump will lift water. The first cause, though it has a tendency to decrease duty in proportion to improved water delivery, has in a still greater degree the tendency to reduce the friction of the pitwork on a given load: yet it is not easy to assign the exact values. On the whole, a reduction of total resistances probably occurs in shafts of equal depth. On the other hand, the great increased depth of many shafts obviously produces a greater proportional friction on load. Under these circumstances, it becomes the fairer method to select the duty of engines working the deepest shafts, for a comparison with the duty of the earlier periods, when engines were worked so differently as the steam. Mr. J. W. Henwood (Wheal Towan) estimates the deficiency of water delivery at 7 or 8 per cent.; Mr. T. Wicksteed (E. Holmbush) 10 per cent. water from three lifts measured and weighed; Mr. Enys (Eldon's engine, United Mines), 4 per cent., measured four strokes of the engine from one plunger lift. The absence of attention in earlier times can only be assumed from the known habits of the miner, and the absurd stories prevalent of particular instances of neglect. Another great, but almost inappreciable change, has occurred within the last ten or fifteen years, in the increase of weight in the rods for a given load; but the circumstance of the greater weight of such rods again allowed of the reciprocal action of a still greater amount of expansion in Watt's engines; and in the heavy pitwork, the accumulated force stored up at the commencement was restored at the end of the stroke; the only loss in duty arises from an increase of the friction of the necessary balance weight; because, while a direct gain is obvious, the same mean power, by a greater amount of expansion, is obtained from a smaller quantity of water expended as steam. The present form of rod, with lifts alternately, where the shaft admits of this method, was probably due to Wat, or Murdoch. Smeaton, at the Chacewater Atmospheric Engine, in 1775 seems to have effected the introduction of one rod for a portion of the shaft, and dispensed with the older practice of tying up to the arch of the beam a separate rod for each lift. The plunger pump seems to have effected another change of some importance, in the velocity with which the larger portion of water is raised. The engines are usually made to go, out of doors, at rather more than half the velocity of the in-door stroke, the piston moving in-door, from 240 to 260 feet, and out of doors from 144 to 156 feet per minute; the velocity of the plunger, or bucket, is usually four-fifths of these amounts, or 110 to 120 feet per minute. Still a portion of the water, from one-third to one-sixth, is raised at three-fourths of the higher velocity; and recently larger valves have been placed below the plunger than above, with a view of equalizing the resistance of the water on passing the valves. A few ex ments of trying an engine in-doors at a very low velocity have been m which may perhaps be extended, to determine the increase of pressure due to different velocities of water in the pumps. The column of mercury, however, only becomes the measure of the total resistances of all kinds,

far as practicable, to be separated, and

to each as nearly as our means of observation admit. In commencing the tion, after the state of rest to which pumping engines are brought, it is possible a greater power may be employed than is required to continue it. Still the term variable load, formerly adopted by the writer of this paper, may be too strong, and the rapid action of the mercury may render it inappreciable. In an attempt to value friction by the area of the rubbing surfaces of the packing of the plungers, it appeared the unanimous opinion of many of the best pitmen, that water could be kept from escaping with less friction by means of twelve-inch packing than with nine inch packing, in a twelve inch plunger-lift—a circumstance that requires attention, not only in this, but probably under numerous other conditions. In regard to the effect of expansion on the pitwork, in producing a variable strain during the load, it was observed, that with twelve times expansion on an engine recently erected, of Watt's construction, including clearance steam, the variation was as 8 to 1 at the end of the stroke; but that in a new engine of combined cylinder, by Sims, in which the expansion after three times in a smaller cylinder indoors, was increased about four times out of doors into a larger cylinder, and which power was converted in-doors into a constant quantity by means of a balance, the variation would be about as 2 to 1; and in Hornblower's or Woolf's, if worked with high steam, that under the condition of twelve times expansion, including clearance steam, the variation might be roughly taken as 3 to 1—that the commercial part of the question of more or less expense in engines or pitwork, would determine the relative advantages, on the whole, of each engine for lifting water from deep mines. It seems that expansion has not been carried out to so great an extent when the load is near the end of the beam, and when the enormous balance weights, usual in Cornish pitwork, are not required to be applied, though it is obvious that this condition causes less pitwork friction.—*Ibid.*

KING'S COLLEGE.

By a prospectus that has reached us of the business of the ensuing session, we perceive that, in accordance with the intimation given in our last number, the department hitherto known at this college as that of "Civil Engineering, and of Science applied to the Arts and Manufacture," is now designated the department of "Engineering, Architecture, Arts and Manufactures."

The course of instruction proposed for students in architecture is as full and satisfactory as that for engineers has been found to be. It extends over three years, and is as follows: "Mathematics; the principles of Mechanics, Hydrostatics and Acoustics; the theory of Construction; the elements of Chemistry; Mineralogy; Geology; the principles of Experimental Philosophy; Geometrical and Perspective, Ornament and Landscape Drawing; Land Surveying; Machinery; the principles and practice of Architecture, including Design and Composition, Construction and Architectural or Building Surveying."

Mr. Hosking has been appointed to the Professorship of the Principles and Practice of Architecture, in addition to his former duties, and he is to be assisted by Mr. Andrew Moseley, a younger brother of the County Surveyor of Middlesex, and of the eminent Professor of Natural Philosophy in the same College. The drawing of enrichments will be taught under the direction of Professor Dyce, of the Government School of Design, and Landscape Drawing by Mr. Cotman, who is well known as an artist, and for his work on the Picturesque Architecture of Normandy.

BITUMEN.

A new application of this material which promises to be of very great service in engineering works, has lately been successfully practised by the Parisian Bitumen Company. The new application consists in cementing large masses of rubble stone with the bitumen in a liquid state, and this has been successfully practised on a very extensive scale on the works of the Upper Medway Navigation Company in the following manner.

The river is divided into levels by weirs and locks in the usual manner. Some of these wiers are constructed at great expense of squared masonry; others are less expensively constructed, by throwing in the rubble stone of the country to the desired shape and height of the weir; it may be remarked that no care is taken in bedding the stones, or in laying them, which is performed by the ordinary labourers of the country. The bitumen is then melted and run in between the stones, and the whole forms a mass of such solidity as to resist the heaviest floods, and is perfectly impervious to water in every part, and it is supposed that it will not require one tenth of the repairs usually bestowed on weirs of the ordinary construction.

It may be noticed that previous to this material being used, the repairs after the winter floods, which are very heavy, were very great, and caused considerable interruption to the traffic.

The great advantages arising from using the bitumen in the manner described are cheapness and facility of construction—a very considerable reduction in the expence of repairs. It is evident that this may be used to very great advantage in foundations of bridges or large buildings, as forming a compact body capable of resisting any pressure, bearing any weight that may be imposed on it, and becoming perfectly solid in five minutes after being laid; it will effectually prevent vermin from getting into houses or burrowing near the foundations.

The manufacture of bitumen is now brought to great perfection by the same Company. Some beautiful specimens of tesselated pavement are being laid of different coloured bitumen, and floors of stations, churches, halls, &c., may be made very ornamental, and equally durable with Yorkshire stone, whilst it is much warmer to the feet and not more than half the price.

Presentation of a Piece of Plate to Mr. Storey, C.E.—A piece of plate value 350 guineas was lately presented to Thomas Storey, Esq.. civil engineer, purchased by subscription and presented as a token of the respect entertained for that gentleman by the different parties connected with the great public works which have been completed under his superintendence. The plate was presented at the Fleece Inn, Darlington, after a sumptuous dinner to which 62 persons sat down. The service consisted of an epergne, elegantly and elaborately chased; a full-sized tureen; two do. sauce-do; four double vegetable dishes, with handles to remove, and to form eight dishes; two 12-inch salvers; four salt-cellars, gilt inside; four spoons do. to match; two gravy spoons; one fish slice; one soup ladle; two do. sauce. On the epergne, the tureen, and six other pieces, the following inscription, surmounted by Mr. Storey's crest, was beautifully engraved:—"This service of plate was presented to Thomas Storey, Esq. C.E., by a number of his friends, as a sincere though inadequate tribute of the esteem and regard they entertain for his professional talents, and private worth." Nicholas Wood, Esq., of Killingworth, C. E., presided, and John Harris, Esq. of Darlington, filled the vice-chair. In proposing Mr. Storey's health, the Chairman said—

"It has, however, been Mr. Storey's lot to extend his services beyond the immediate district. Of the great line of communication between England and Scotland—the great chain of communication—he has had the good fortune to execute a link; and I may add that it is a pretty long link. Now when I call to remembrance that it is 45 miles, I venture to say that this link will bear a comparison with any other link in the chain between London and Darlington (immense cheering). Gentlemen, I have heard only one opinion of that link; which is, that it is the smoothest and best piece of road between London and here (cheers). When I mention a "chain," I speak of the great lines of communication—the great public railways, and when I allude to the railway from Darlington, I do not refer to the various local lines which are more immediately connected with the transmission of coals; but I allude to the line between York and Darlington, which I think will bear comparison with any of the great lines that lie between this place and London (applause)."

Removal of the North Pier Light-house.—We have this week to record one of the most ingenious efforts of mechanical skill, which has ever been exhibited in the town of Sunderland. The enterprising engineer to the Commissioners of the River Wear, John Murray, Esq., who has already manifested so much ability in improving our harbour, and our noble piers, has long been engaged in erecting a new pier on the north side of the river, for the purpose of widening the entrance to the port, and this being now nearly completed, it has become necessary to remove the lighthouse from the old pier to the present splendid erection. To give our distant readers an idea of the difficulty, we may state that the height of the lighthouse is 68 feet, and its weight 280 tons. It was on Monday last, the 2nd inst., every thing having been prepared for the attempt, that Mr. Murray carried the first part of his design into execution, and actually succeeded in moving the ponderous mass 20 feet 5 inches to the northwards. The means by which this was accomplished will seem very simple when explained to our readers; but in reality great ingenuity was requisite in overcoming difficulties, which, to many persons, seemed to present obstacles altogether insuperable. Five principal pulling screws were strongly fixed to the glacis in front of the building, and were attached to chains fastened to the cradle upon which the lighthouse stands. These screws were worked by 24 men. In addition to these, there were four screws behind the cradle to assist in propelling it, which were worked by three men each; the total number of men employed on the occasion was forty. The cradle was supported on a great number of wheels, which travelled on eight parallel lines of rails, and the entrance end of the bracing was supported on slide balks. Operations were commenced at half-past three P.M., and at a few minutes after eight it was safely landed on the new pier, where it now stands, without the slightest accident having taken place. The building is now intended to be carried 150 yards to the eastward, or very nearly to the end of the New Pier, and for that purpose it will be blocked up in its present situation, until the railways and wheel timbers are reversed, which part of the work will occupy about a fortnight, when it is intended to resume the operations for its removal.—*Sunderland Advertiser, Aug. 6.*

LEGAL CONSTRUCTION OF RAILWAY ACTS AS TO BRIDGE BUILDING.

The Queen v. Walker and Another, and the Birmingham and Gloucester Railway Company.—(De Montpelier Street.)—This was an indictment against the Birmingham and Gloucester Railway Company for a nuisance. The bill was found at the January sessions, and having been removed into the Court of

Queen's Bench, by writ of *certiorari* obtained by the defendants, it came down to be tried on the civil side.

Mr. Serjeant Goulburn, Mr. Humfrey, and Mr. Daniel appeared for the prosecution; and Mr. Hill, Q.C., Mr. Clarke, and Mr. Spooner for the defendants.

It appeared that the company had erected a bridge for the purpose of carrying their railway over Montpelier Street, at Highgate, near Birmingham, which street it crossed nearly at right angles. The 46th section of the Company's Act of Parliament provides, "that where any bridge shall be erected by the said company for the purpose of carrying the said railway over or across any public carriage road the span of the arch of such bridge shall be formed, and shall at all times be, and be continued, of such width as to leave a clear and open space under every such arch of not less than 15 feet, and a height from the surface of the road to the centre of such arch of not less than 16 feet, and the descent under any such bridge shall not exceed one foot in 13 feet."

By the 48th section of the same act it is provided, that "whenever the said railway shall cross any public footpath not on a level, the said company shall raise or lower the said footpath so as to preserve an ascent or descent, as the case may require, of not more than one foot in 13 feet."

The span of the bridge in question over the carriage way was 16 feet, being one foot more than the span mentioned in the act, but about four feet less than the original width of the road. The company had at first intended to obtain the required height of 16 feet under the arch by lowering the surface of the road, but at the request (as was stated) of some of the neighbouring inhabitants, who apprehended inconvenience from such a declivity, they had only lowered the road about seven feet, leaving a headway of ten feet eight inches.

When, however, the bill of indictment had been found against them, they excavated the road about five feet more, but not, it appeared, sufficiently by about six inches to give the full height of 16 feet. This excavation rendered it necessary to build retaining walls of 96 yards in length to support the footpaths on each side of the carriage way, the thickness of these retaining walls being an encroachment on the original width of the carriage way till they reached the bridge. At first no provision had been made for the footpaths, but subsequently the piers of the bridge had been cut through, and the footways had been carried through them, descending under the railway by steps, and ascending in the same manner on the other side.

Mr. Serjeant Goulburn opened the case on behalf of Mr. Unett, the prosecutor, the proprietor of an estate in the neighbourhood, and contended that the company were bound to preserve the road of its original width, and had no right to contract it by means of their bridge; that the width of 15 feet mentioned in the act was a provision only applicable to cases where the road had been originally of no greater width, or of less width than 15 feet, and was the minimum, not the maximum width which the company were bound to leave; that the company were not justified in lowering the surface of the road, but ought to have obtained their height of 16 feet from the surface of the road to the centre of the arch, by taking the railway across the road at a higher level; that with respect to the retaining walls they were an encroachment upon the approach to the bridge, and were not justified by the act; and with respect to the footpaths the company had no right to contract their width where they were carried through the piers of the bridge, nor to carry them underneath the railway by means of steps.

Mr. Justice Parke, on the counsel for the prosecution calling Mr. Hornblower, architect and surveyor, of Birmingham, as the first witness, suggested that the case appeared to be a question of law upon the construction of the act of parliament, more than a question of fact, and enquired if the facts could not be agreed upon. It was ultimately arranged that Mr. Hornblower's examination should be proceeded with, as the shortest way of eliciting the facts, which were proved by him to the effect above stated.

Mr. Justice Parke then ruled:—1st. That the company were not bound to preserve the road of its former width, but had a right to contract it by means of the bridge, provided they left a width of not less than 15 feet.—2nd. That the company had a right to lower the surface of the road in order to obtain a height of 16 feet under the arch, and that they might lower the road either before or after they had built the bridge.—3rd. That the company had no right to contract the carriage way in its approach to the bridge by the retaining walls.—4th. That the company had not complied with their act by carrying the footpaths under the railway by means of steps; but as this plan appeared the most convenient to the public, and as the sloping of the footpath, in lieu of steps, would render it necessary to underbuild the houses, the court would not compel the company to alter the footpaths.

At the suggestion of the judge, and by the consent of the parties, a verdict was entered for the crown, the company entering into a rule to widen the carriage way by pulling down the retaining walls, and throwing them back into the footpath, and undertaking to lower the road still further, so as to leave a height of 16 feet clear from the surface of the road to the girders of the bridge.

The costs to be taxed by Mr. Hilditch.

The Queen v. Same.—This was an indictment for a similar nuisance in Highgate Place.—A like verdict was taken.—*Midland Counties Herald.*

ST. GEORGE'S CHAPEL, WINDSOR.

August 2.

For some years past the grand western window of this edifice has been considered to be in an extremely dangerous position, and very far from secure, in consequence of its bulging considerably inwards in many of its parts to the extent of several inches.

About 10 or 12 years since, the late Sir Jeffry Wyatville minutely examined the stone work of the window, and in consequence of his report it was determined it should undergo the necessary repairs under Sir Jeffry's superintendance; but, in consequence of the architect's then engagements, the repairs were not proceeded with.

The Dean and Canons, however, have just decided that the massive stone work shall be taken down, and the whole window entirely rebuilt, preserving the valuable stained glass it contains for replacement. The execution of this work, which will require the greatest care, so as not to injure some of the finest specimens of painted glass in the kingdom, has been intrusted to Mr. Blore, the architect, by the Dean and Canons.

The great painted window, over the altar, representing the Resurrection of our Saviour, divided into three compartments, designed by the late Benjamin West, and executed by Messrs. Jarvis and Forest, in 1788, has hitherto been seen to great advantage, in consequence of the three windows on the north and south sides of the west-end of the choir having been darkened (to give greater effect to the design), and painted over with the arms of the Sovereign and Knights Companions of the Order of the Garter in 1782, 1799, 1805, and 1812. The arms of each knight are encompassed with the Star and Garter, and surmounted with his crest and coronet. The George is beneath, affixed to a blue riband, on which the Christian name and title are inscribed. These six windows are to be immediately taken out, and for the darkened glass there is to be substituted transparent painted glass (containing the arms of the Sovereign and the Knights, and other heraldic devices), thus giving an air of great lightness and elegance to this part of the chapel, although, at the same time, very materially diminishing the grandeur and effect of the large painted window over the altar.

One of the windows was completed on Saturday July 31, and judging of the effect which will be produced from this one only, the alteration decided upon by the Dean and Canons will greatly improve the general appearance of the interior of the chapel. It will only require the remainder of the windows of the choir, which are now plain, to be of stained glass, to render St. George's Chapel one of the most imposing and magnificent sacred edifices in the kingdom.

The painted glass for the six windows referred to has been executed by and under the superintendence of Willemont

Except on Sundays the chapel has been closed for several weeks past, in order that no delay may take place in the completion of the work.

The splendid organ, which is considered to be one of the finest instruments in England, has just undergone a thorough repair by Gray. The old keys, which were upwards of 50 years old, and completely worn through, have been replaced by new ones, and several additions have been made to the pipes.

As soon as the improvements now in progress are completed, it is the intention of the Dean and Canons that the whole of the interior of the chapel shall undergo a complete and thorough cleansing and repair. Nothing has been done to the chapel in these respects during the last half century.

THE RIVER CLYDE.

At a meeting of the River Trust held on Tuesday, 27th July last, Mr. James Hutchison called the attention of the Trust to a matter of the last importance, viz. the extent to which the river should be widened. In the Bill which had lately passed Parliament powers had been taken to widen the river vastly beyond its present breadth, but if these powers were acted upon to their full extent, the time occupied in the operations, and the vast increase which it would cause in the expense of dredging and maintaining the extended river at the proper depth would be such as to place the Trust in a most dangerous position; and Mr. Bald had given it as his opinion that it might be productive of ultimate ruin. Mr. Bald had, however, prepared a plan of the contemplated improvements, similar to those which had been approved of in 1836, and though this plan did not widen the river to the extent which they had power to widen it by the Act of Parliament, still it must be admitted by all that it would improve the river sufficiently to accommodate the most extensive trade which could be reasonably expected to belong in after years to the harbour of Glasgow.

Mr. Bald briefly addressed the Trust, in explanation of his plans. From his remarks we learn that the width of the river from the bottom of harbour (at which it is intended to commence operations,) down to Renfrew, varies at present from 165 to 190 feet. It was his intention, however, to increase this width to 300 feet at the bottom of the harbour; to 310 at the mouth of the Kelvin, and to 325 at Renfrew Ferry; and at the same time to "sweeten" the course, or, in other words, to remove angles and jutting points, and to make the line a straight one. If the Clyde were thus widened it would be sufficient for any increase of trade that would come to it. By not going beyond this proposed width, the channel would deepen itself, and of the progress of this deepening process, they had that day an example in the arrival in their harbour of a ship drawing 17 feet water; and he anticipated, that in a few years, if the large or extended plan were not adopted, that the depth would increase to from 18 to 20 feet. He considered the proposition to increase the width of the river to 400 feet, beginning immediately below the harbour, to be most unwise, and one which he would not advise, even though the Trust might possess the means to execute it. It would take 70 years to complete the operations according to this extended plan, and when once finished the expense of maintaining it would be absolutely ruinous.

To a question from Mr. Burns,

Mr. Bald replied, that it was a law recognised by all engineers that if the channel of a river were widened beyond the proportion of its depth, it became more shallow, from the slower motion of the current. If, on the other hand, it was narrowed beyond this proportion, it had a tendency to become deeper from the more rapid motion of the stream, particularly in land floods. He instanced three places in the river, the harbour being one of them, where deposits were continually taking place, from their being unusually wide.—Were it otherwise, this silt or deposit would be at once removed by the land flood to the sea.

Mr. James Hutchison explained, that at the time it was resolved to powers to widen the river to a great extent by the last Bill, Mr. Walker, upon making out the plans, informed them that if the breadth of the river was at any time extended according to these plans, they must make up their minds to the maintaining of it by dredging being immense.

After a conversational discussion of some length, it was finally resolved that Mr. Bald's modified plans should be adopted, and, as we understood, that operations should be commenced immediately.—*Glasgow Argus.*

STEAM NAVIGATION.

The Iron War Steamer Phlegethon.—We perceive, by the Calcutta papers brought by the India mail, that this vessel, which was built by Mr. John Laird, of North Birkenhead, for the East India Company, has arrived at that port. She is about 800 tons measurement, armed with two 32-pounders and other small guns, and is exactly the same size and model as the former iron war steamer, the Nemesis. She was to sail for China about the middle of June, to join the expedition. It was reported in the Bombay papers, that two armed steamers, the Ariadne and Medusa, both built by Mr. Laird, carrying each two 26-pounders, would be ordered to China: they would make an effective flotilla of four powerful iron armed steamers attached to the expedition, and, from the services rendered by the Nemesis, are likely to prove a great acquisition. The following extract of a letter, dated Calcutta, June 5, gives an account of the Phlegethon:—"I am too full of business to write at length just now; but you will be delighted to hear we arrived at this place on the 22nd of last month, as sound in hull, boilers, and engines as when we left England. We have had some severe trials, and a large share of stormy bad weather. The Phlegethon, in bad weather, has surpassed my most sanguine expectations, and having gone over 17,157 miles without straining a rivet, will I consider quite carry out the principle that these sort of vessels can navigate in security between England and India."—*Liverpool Albion.*

The Steam Ship "Admiral."—In these days of steam triumphs, we have frequently had to record the achievements of mechanic art, as applied to steam-ships of leviathan dimensions, as well as of the consummate skill displayed in the performance and management, and we remember few that have possessed greater claim to public attention than the splendid steamer *Admiral* now running between Liverpool and Glasgow, the same line on which the *Achilles, Commodore, Actæon, City of Glasgow*, and *Princess Royal*, all splendid steamers, are employed. The *Admiral* is a vessel well worthy of her name and lineage, and, whether the size and beauty of the ship, her excellent accommodations, or the great power and perfection of her machinery be the object of admiration, it must be admitted, that in each of these departments, she has never been surpassed. The engines supplied to this vessel are of unusual power and beauty of construction, fitted up with expansion gear, and possessing all the latest improvements: they were produced at the Glasgow Vulcan Foundry, and are of 200 horse power. It is a matter of great interest to witness the cleanliness and order always observed in the engine-room, and the great care and attention of the engineers are particularly worthy of notice for skill and sobriety: neither is the grand desideratum to a landsman (roomy accommodation) to be forgotten. There are 107 sleeping berths, all of the most ample dimensions, a limited number of which are divided off into state apartments. The grand saloon, around which these state apartments are arranged, is a magnificent room, and unites extreme comfort with ornament; on either side of it tables are ranged with elegant seats of richly carved oak, uniform with the chase panelling and groined roof. The entire fittings are of the most costly description, and the cuisine is excellent and cheap. The range of the *Admiral's* deck is 220 feet, it is perfectly flush, and forms a beautiful and unbroken promenade. The *Admiral* is a vessel of the same class and under control of the same business management at Liverpool as the Halifax line of steamers, and the same system of speed, punctuality, and good order which has obtained an exalted reputation for the Atlantic steamers prevails here, and has met with equal success.—*Morning Herald.*

MISCELLANEA.

ELECTRO-MAGNETIC PRINTING.

On Monday, 2nd ult., the first public exhibition of Mr. Bains's electro-magnetic printing-machine took place in the Lecture-room of the Royal Polytechnic Institution.

apparatus consists of a dial-plate, inscribed with the alphabet and numerals, with a revolving hand, worked by ordinary clock-work. On the other side of the room stood the important portion of the invention—that which furnished in type the communication to be sent forth from the dial-plate already described. Between these two machines a connexion (capable [illegible] extended in practice to any length) by means of wire conductors, communicating with two electro-magnets placed on a frame, and connected with a cylinder covered with paper, upon which the type was to leave its im[illegible] an horizontal wheel, in which types to correspond with the lette[illegible] and figures on the dial were fixed. This wheel was ingeniously brought in contact with an inking roller, and these three portions of the machine were all brought into motion horizontally.

The party directing the communication stands at the dial-plate first described, and fixes a peg under the letter desired to be communicated. The [illegible] its rotation until its progress is arrested by coming in contact with the peg. A small trigger is then pulled, the galvanic power is then brought to bear by the aid of the communicating wires upon the two electro-magnets, with their machinery on the second frame, and the letter thus communicated is printed upon the paper affixed to the cylinder.

The operations excited universal admiration, and the machine itself is well worthy the attention of the curious, for though at present it may fail as a speedy means of communicating information in print, still by the adoption of a code of signals (by which one letter or character might be construed to denote a sentence or describe a subject) the invention might be made extremely valuable in the times in which we live.

Electro-magnetic Exhibition.—A very interesting exhibition has been lately opened at No. 8, St. Andrew Square, Edinburgh. It consists of several working models of different machines, such as a turning-lathe, a printing-machine, a saw-mill, and a locomotive carriage, driven by the power of electro-magnetism. The inventor of these models is Mr. Robert Davidson, an ingenious mechanic from Aberdeen, who has been engaged upon them for the last four years, and who has succeeded in effecting several improvements in the application of electro-magnetism, which promise to be of great practical value. He is the first, we understand, who has employed the electro-magnetic power in producing motion, by simply suspending the magnetism without a change of poles. The mode employed by Jacobi, Davenport, and Storrar, consisted in keeping the repulsive power (which is equal to a third only of the attractive power) in operation during the one half of the time, and the attractive power during the other half. Mr. Davidson's discovery consists in a simple and extremely ingenious method of communicating and cutting off alternately the galvanic current to and from a pair of electro-magnets that always act attractively, so as to exert a constant moving force upon the machine which is put in action. It has received the approbation of numerous scientific gentlemen, who consider that Mr. Davidson has succeeded in showing the perfect applicability of magnetism as a motive power to engines of every description. It would no doubt be desirable, however, to see experiments tried on a larger scale; which Mr. Davidson, we understand, is anxious to do, but is deterred by the want of funds.—*Scotsman.*

Travelling by Electro-magnetic Power.—We are informed that a distance of 57 miles has been travelled on the common road, in a Bath chair, by electro-magnetic power, in one hour and a half; and further, that the applier comes over daily from St. Alban's to the Bank of England in the said chair in half an hour at an expense of sixpence. The model of an electro-magnetic engine, which has been exhibiting at the Adelaide Gallery for some time, is an instance of ingenious mechanic arrangement, whereby contact is broken and renewed, the poles reversed, &c.; and from its performances gave great promise of practical powers on a larger scale. The battery employed is the nitric acid, or Grove's battery. Of the invention that has done the great feat, and established the successful application of this wonderful agent, we know little more than its success. We hear that the increase of power is due to the discovery of a new combination of elements; that this is the secret of the moving power; and that the battery is to be the subject of a a patent.—*Literary Gazette.*

Edinburgh and Glasgow Railway.—It is gratifying to observe the incessant exertions which are making everywhere on the line in the vicinity of this city to get this national undertaking completed. The magnificent entrance to our great tunnel is drawing to a conclusion, while the booking and other offices are all but finished. The landing and departing platforms are now getting very handsome sheds, with elegant cast iron supports set up; and the ground is clearing out for laying the permanent rails. Yesterday Mr. John Craig, the mineralogist, made a survey of the tunnel, in furtherance of the objects of the British Association, and proceeded right through it, in company with the very polite and spirited contractor, Mr. Marshall. Amongst many other geological specimens got in the journey, we saw perfect masses of the *Nucula Tumida, Productu Scotia, Producta Martinnii, Bellerophon Urii*, and *Apiocrinites*, imbedded in a shale, above a two feet limestone, with many other interesting remains of a period long before the creation of man.—*Glasgow Constitutional*, August 4.

London and Brighton Railway.—The Brighton terminus is now completed externally. All the works are on a magnificent scale; and the passengers' sheds and station vie with any works of a similar kind in the kingdom. The station is even larger than that at the London terminus of the Birmingham Railway in Euston-square; and the edifice forms a pleasing and prominent object from various parts of the town.—*Brighton Gazette.*

Bristol and Glocester Railway.—The works on this line are proceeding rapidly in the neighbourhood of Wickwar, where 600 additional labourers have been put on this week.—*Glocestershire Chronicle.*

Cheltenham and Great Western Union Railway.—Contracts have been taken, and in some instances the works have been commenced, for carrying on this line from its present terminus at Cirencester towards Stroud and Gloucester. —*Cheltenham Looker-on.*

Paris and Rouen Railway.—This great work is proceeding rapidly, under the superintendence of Mr. Locke; and we understand that thirty-five miles of the Paris end of the line will be opened early in the spring of next year.

Railroad from Berlin to Hamburgh on the right bank of the Elbe.—The *Hamburgh Gazette*, under date Berlin, the 24th ult., announces that a commencement had been made in this affair. The provisional committee was appointed definitively, with power to adopt resolutions. This enterprise was calculated to consolidate the interests of so many people, that the most perfect accordance was necessary. The number of subscribers amounted to 5,000.

Railway Filters.—For some time a number of men have been employed in the erection of filters on the top of the terminus of the Greenwich Railway, for the purpose of supplying the engines with pure water, it having been discovered that the water that has been used has occasioned considerable injury and wear to the machinery. There are also similar filters erected at the New Cross station, on the Croydon line.

A Cast-Iron Light-house.—The necessity for a lighthouse to facilitate the navigation of the windward passage by the Morant point, in the island of Jamaica, so as to enable vessels to avoid the Morant Cays, a dangerous reef of rocks, 25 miles southward of that point, having been long felt by the authorities of the island, they have determined upon the erection of a tower and lights for that object, upon the recommendation and under the direction of their consulting engineer, Mr. Alexander Gordon; and it may now be seen in a very advanced state of forwardness, from the road at Pimlico, erecting on the works of Charles Robinson, proprietor of the long-known establishment of Bramah and Sons. It forms a most conspicuous and imposing object as it rears its head above the surrounding buildings; and when completed to its full height, 100 feet, will doubtless attract much notice from its novelty. The diameter of the base is 18¼ feet, tapering gradually to 11 feet under the cap, which supports the lantern containing the lights and reflectors, which, with the actuating apparatus for revolving the lights, are constructing by Deville, of the Strand.

The Dry Rot.—Government have recently ordered the opening of the fungus pits in Woolwich dockyards, which had been closed in August, 1836, for the purpose of testing the virtues of Sir W. Burnett's process for rendering wood, cordage, and all descriptions of woollen free from the effects of dry rot. The result, it would appear from the reports of the officers deputed by the Admiralty to superintend the experiments, is in every way successful, the prepared wood being as clear and sound when it came out as when first deposited.—*Inventors' Advocate.*

Thames Tunnel.—The shaft of the Thames Tunnel on the Wapping side of the river, in which the circular staircase is to be formed for foot passengers, has now almost entirely disappeared, and not more than five feet of it appears above the ground. A month ago it was on a level with the tops of the adjoining houses, and its gradual sinking as the earth below is excavated has excited the surprise of the inhabitants. In depth it is 60 feet, and it will be raised 15 feet higher, and again sunk. Since the engineer of the Tunnel, Sir Isambard Brunel, and three other gentlemen, passed under the driftway connecting the shaft with the Tunnel, many others have passed from one shore to the other by the same means. The completion of this stupendous work is close at hand.

Asphalte.—For some time past the Seyssel Asphalte Company's men have been actively engaged on the New Junction line of the Greenwich Railway, in covering the arches, which when completed will extend over a space of 400,000 feet.

New Steamers.—On the 21st instant a fine steam vessel was launched from the building yard of W. Pitcher, at Northfleet. She is for the Sicilian Government, and named the "Maria Teresa," her tonnage is about 300, and the collective power of her engine will be 120 horses, manufactured by Messrs. Boulton, Watt & Co. of Soho. A second vessel for the same government is in considerable progress, of smaller dimension to carry two 50-horse engines, from the same establishment.

A Miniature Steamer called the "Fire Fly," has been astonishing the frequenters of the Thames by its rapid evolutions on the river, she is a moderate sized boat propelled by Ericsson's propeller fitted in the stern and driven by two oscillating engines, set *horizontally*, and at right angles the crank shaft. The diameter of the cylinder is only 3 inches, and 6-inch stroke, making 180 to 200 strokes per minute, worked with high pressure steam of 50 to 60 lb. on the square inch, generated by a very compact locomotive boiler. The engines and boiler were entirely constructed by Mr. Warriner, formerly a pupil of Messrs. Braithwaite, Milner and Co., the engines possess several improvements worth introducing in larger engines, particularly the method adopted of conveying the steam into the cylinders instead of through the gudgeons, upon which the cylinders oscillate. She steams about 8 to 9 miles per hour through the water, and has run with the tide from Blackwall to Westminster Bridge in 50 minutes.

Captain Ericsson is now in New York, and engaged by the American Government to construct two engines of 1,000 horse power collectively for a large sea-going vessel to be propelled by the Captain's propellers.

Galvano-plastic Casts.—A letter from Munich informs us that the celebrated Bavarian sculptor Stigelmayer has brought to such a pitch of perfection his galvano-plastic process, that its effects would be deemed fabulous were they not publicly exhibited in the Museum of the Society of Arts. In the space of two or three hours colossal statues in plaster are covered with a coat of copper, which takes with the greatest accuracy the most minute and delicate touches, giving the whole all the appearance and solidity of the finest casts in bronze. M. Stigelmayer has also applied his process to the smallest objects, as flowers, plants, and even insects, bringing them out with such accuracy, that they seem to have been executed by the hands of the most skilful artists.

Highest Chimney in the World.—The highest chimney in the world is at the soda ash manufactory of James Muspratt, Esq., near Liverpool. It is the enormous height of 406 feet above the ground, 45 feet diameter inside at the base, 9 feet ditto at the top, and contains nearly 4,000,000 of bricks.—*Daily paper.*

LIST OF NEW PATENTS.

GRANTED IN ENGLAND FROM 28TH JULY, TO 27TH AUGUST, 1841.

Six Months allowed for Enrolment.

JOSEPH RATCLIFFE, of Birmingham, manufacturer, for "*certain improvements in the construction and manufacture of hinges for hanging and closing doors.*" (A communication.)—Sealed August 4.

OWEN WILLIAMS, of Basing Lane, London, engineer, for "*improvements in propelling vessels.*"—August 4.

JOHN LEE, of Newcastle-upon-Tyne, manufacturing chemist, for "*improvements in the manufacture of chlorine.*"—August 4.

JAMES WARREN, of Montague Terrace, Mile End Road, for "*an improved machine for making screws.*"—August 4.

STOPFORD THOMAS JONES, Tavistock-place, Russell Square, gentleman, for "*certain improvements in machinery for propelling by steam or other power.*"—August 4.

WILLIAM CRAIG, engineer, ROBERT JARVIE, rope-maker, and JAMES JARVIE, rope-maker, all of Glasgow, in the kingdom of Scotland, for "*certain improvements in machinery for preparing and spinning hemp, flax, wool, and other fibrous materials.*"—August 11.

SAMUEL BROWN, of Gravel-lane, Southwark, engineer, for "*improvements in the manufacture of metallic casks or vessels, and in tinning or zincing metal for such and other purposes.*"—August 11.

JOHN SEAWARD, and SAMUEL SEAWARD, of the Canal Iron Works, Poplar, engineers, for "*certain improvements in steam engines.*"—August 13.

WILLIAM HALE, engineer, and EDWARD DELL, merchant, both of Woolwich, for "*improvements in cases and Magazines for gun-powder.*"—August 13.

JOHN HARVIG, of the Strand, gentleman, and FELIX MOREAU, of Holywell-street, Millbank, sculptor, for "*a new and improved mode or process of cutting or working cork for various purposes.*"—August 21.

JOHN HARVIG, of the Strand, gentleman, and FELIX MOREAU of Holywell-street, Millbank, sculptor, for "*a new or improved process or processes for sculpturing, moulding, engraving, and polishing stone, metals, and other substances.*"—August 21.

JOHN THOMAS CARR, of the town and county of Newcastle-upon-Tyne, for "*improvements in steam engines.*" (A communication.)—August 21.

GEORGE HICKES, of Manchester, agent, for "*an improved machine for cleaning or freeing wool, and other fibrous materials, or furs and other extraneous substances.*"—August 21.

CHARLES DE BERGUE, of Broad-street, London, merchant, for "*improvements in axletrees and axletree boxes.*" (A communication.)—August 21.

FREDERICK DE MOLEYNS, of Cheltenham, gentleman, for "*certain improvements in the production or development of electricity, and the application of electricity for the obtainment of illumination and motion.*"—August 21.

WILLIAM WALKER JENKINS, of Gred, in the county of Worcester, manufacturer, for "*certain improvements in machines for the making of pins, and sticking the same into paper.*"—August 27.

EDMUND MOREWOOD, of Highgate, Middlesex, gentleman, for "*an improved mode of preserving iron and other metals from oxidation or rust.*" (A communication.)—August 27.

MILES BERRY, of Chancery-lane, civil engineer, for "*certain improvements in the means and apparatus for obtaining motive power, and rendering more effective the use of known agents of motion.*" (A communication.)—August 27.

SAMUEL HARDMAN, of Farnworth, near Lancaster, spindle and fly-maker, for "*certain improvements in machinery or apparatus for roving slubbing cotton and other fibrous substances.*"—August 27.

THOMAS CHAMBERS and FRANCIS MARK FRANKLIN, of Lawrence-lane, London, and CHARLES ROWLEY, of Birmingham, button manufacturer, for "*improvements in the manufacture of buttons and fastenings for wearing apparel.*"—August 27.

TO CORRESPONDENTS.

"G. Coe."—*On Reversing Engines; an accident occurred, as we were going to press, which damaged the engravings, we were therefore obliged to postpone the notice until next month.*

Severn Navigation.—*We have received a very valuable report by Mr. Fulljames, on the proposed improvements of the river, well deserving a perusal by all parties connected with this long contested "improvement."*

Mr. Brooks and Mr. Barrett.—*After a careful perusal of the communications from these two gentlemen, we have determined not to insert them, as we feel convinced that they will only lead to an endless altercation between both parties.*

We must request the favour of our correspondents, who may favour us with articles which require engravings to illustrate them, to let the drawings be separate from the manuscript, and drawn on thin paper—good tracing paper is the best, and if possible to draw them so that they shall come within the width of a column (3½ inches), or the width of a page (7 inches.)

Communications are requested to be addressed to "The Editor of the Civil Engineer, and Architect's Journal," *No.* 11, *Parliament Street, Westminster.*

Books for Review must be sent early in the month, communications on or before the 20th (if with drawings, earlier), and advertisements on or before the 25th instant.

Vols. I, II, and III, may be had, bound in cloth, price £1 each Volume

ERATTA.

HISTORY OF DECORATIVE SCULPTURE IN FRANCE.

(Concluded from page 259.)

When the kings of the first race founded the French kingdom, they built churches, some of which are mentioned by Gregory of Tours (B. 2 § 14, 15, &c.), but which have all unfortunately been destroyed. Some remains of these primitive edifices are still however to be seen in marble capitals used in the churches rebuilt after the Norman ravages. Thus at Montmartre there are capitals of white marble, the style of which calls to mind degenerate antique forms, and which can only be assigned to the first ages of Christianity; this is evident from the Greek cross still to be seen on the volutes of one of them, the irregular management of the foliage, the inferior execution, and the sharp forms which made their appearance with Christianity, and did not leave until the Revival. These are features belonging to a period of art very nearly approaching the Lower Empire, but Christian notwithstanding as the emblems plainly show. At Jouarre, a place famous for its abbey, is still to be seen a subterranean chapel at the end of the cemetery, having, like the church of Montmartre, several capitals of white marble, which in the singular form of their leaves, and in the variety of their composition, since there are no two alike, show more of the classic character of antiquity, and on the contrary present all those which are proper to the first centuries of Christianity. The church of St. Denis has on several capitals *fleurons*, like those of Jouarre, and which might have formed part of the church of Dagobert. To the same period a Greek cross, found some years ago behind the apsis of the present church, appears to belong. The ruins of the Abbey of St. Medard, at Soissons, have among them a marble capital, in which may be recognized the degenerated traces of ancient art, and seeming to belong to some of the edifices of the kings of Soissons, who were buried at St. Medard.

Between this first period of modern civilization and the eleventh century, monuments are wanting to enable us to follow up step by step the history of the subject before us, a deficiency which must no doubt be attributed to the numerous invasions, which took place during the Carlovingian reigns. When the reign of the Capets commenced Robert the Pious rebuilt the churches, and art took a new direction, of which there is now abundant evidence. The church of St. Germain des Prés, at Paris, for instance, notwithstanding many details attributable to the barbarism of the age, has some fine parts, particularly around the choir. There, the capitals, composed of large leaves, contain chimerical animals, contributing to the effect of the composition, and the great variety which prevails is good proof of the rich and fertile imaginations of the medieval artists. At this period the leaves of the acanthus and the volutes, with other elements of ancient ornament, still formed part of decoration, but their general forms were entirely modified. The historical capitals of the nave of St. Germain are also of the eleventh century, and are not less interesting than those of the choir. (See Figs. 1 and 2.)

During this period of art, the capitals form two very distinct classes, 1st, of those in which, in imitation of the Pagans, Christian artists only imitated foliage as the basis of decoration; 2nd, capitals enriched with human or animal figures, and of which the origin is also to be found among the ancients. The first are evidently a consequence of the capitals of the first period of our era, of which we have mentioned that there are examples at Montmartre, St. Denis and Jouarre. In the eleventh century they exhibit an imitation more or less exact of the Corinthian column. The ornaments of the astragal of the capital in the church of St. Spire at Corbeil, and of Esnay at Lyons, are composed of water leaves, imitated from the antique, and executed badly enough. In the cloister of Moissac they are replaced by Byzantine rosettes. The foliage of this period presents acute forms, removing the artist from the study of nature, a direction which was given to art by the Orientals in the time of Justinian, and afterwards adopted in the west. Above the astragal is the capital, differing from that of the ancients as it takes every imaginable geometric figure, the details of the Corinthian foliage gradually disappearing and giving place to original compositions, sometimes not without harmony and taste. The subjoined capital from the church of St. Germain des Prés is an instance of this.

During the whole period, included between the last Carlovingians and the 13th century, the principal elements of ornamental sculpture are an imitation, more or less good, of the acanthus, their leaves edged with pearls, palms, scrolls, and other exotic types.

The second class of medieval capitals is distinguished from the first by heads of men and animals, chimeras, and sea or land monsters, mixed up with some foliage imitated from the oriental flora, and which are afterwards succeeded by religious, historical, or symbolical subjects covering the whole surface of the capital to the exclusion of other

Fig. 1.

Fig. 2.

Capitals at the Church St. Germain des Pres.

ornament. This second system, like the first, owes its origin to antiquity. The Etruscans often mixed up the heads of men with foliage in their capitals;* the Romans introduced persons on foot, of which a fine example is to be found in St. Lawrence without the Walls. Without leaving France, ancient examples are to be found of this mode of decoration, as at Vienne in Dauphiny, where on a beautiful Corinthian marble capital of large proportion, are four heads of Pagan divinities. The Museum of the same city contains a fragment seemingly rather later, and in which are also figures and animals in the midst of foliage. A Medusa's head is in the middle, two serpents intertwined form the volutes, which rest on large acanthus leaves. The church of St. Germain des Prés shows the whole progress of the system, some of the capitals being covered with historical and religious subjects. (Vide Fig. 2.) The royal vault in the subterranean church of St. Denis, is decorated with purely historical capitals, representing kings of France, bishops removing relics, &c. (Vide Fig. 3.)

Fig. 3.

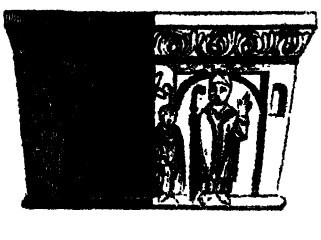

Fig. 4.

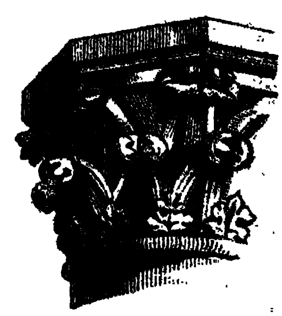

Capitals at the Church St. Denis.

In the 12th century national art acquired a less barbarous tendency, and in St. Denis, we see in the parts built by the Abbot Suger, capitals of good character and scrollwork still more remarkable, forming the decoration of the pilasters of the north side door to the cemetery of the Valesians. At this period, more than in the preceding, painting was applied in aid of sculpture, and in the next century, it attained its complete development. Even in the 12th century the Christian artists, deprived of ancient models, sought for the elements of ornament in the national flora; and in the succeeding period the acanthus and all the exotic plants were wholly excluded from sculpture, and gave way to French flowers and foliage. The execution of ornament in the end of the 12th and 13th centuries is very good, for the sculptor, being perfectly acquainted with the forms he was to imitate, produced broad and noble compositions, in a style which, although severe, was completely in harmony with the buildings. In the 13th century Peter of Montereau, architect to St. Louis, one of the most skilful artists of his time, gave new vigour to the art of decoration; he introduced in the chapel of Our Lady in the church of St. Germain des Prés, and the Sainte Chapelle of the Palais, ornaments of remarkable precision and taste. Notre Dame, which has some parts of the same date, shows in the great capitals, supporting the columns of the nave, and in the details of the doors, how much the art of the sculptor was advanced.

* See an example in the British Museum.—Edit.

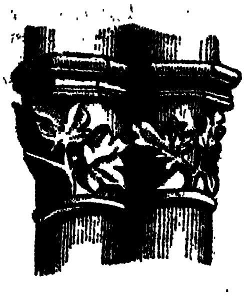
Fig. 6.



Capitals at the St. Chapelle, Paris.

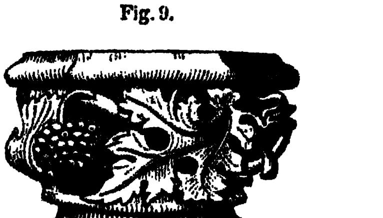
Figs. 7 and 8.

Ornaments from the Church Notre Dame, Paris.

The capitals of the Hotel de Dieu at Paris, of the Abbey of Poissy, of the front of St. Julian the Poor, &c., were so many masterpieces of the luxuriant imagination of the decorators of the 13th century. Among the examples of this period may also be classed the beautiful ironwork of the gates of Notre Dame; it is composed of scrollwork in the best taste and of the finest execution. The date of it is not decided; but it evidently belongs to the 13th century, agreeing in style with the ornament of the rest of the building. In the gate in the middle of the grand front the skilful artist has intermingled birds, winged dragons and foliage, with a statue of St. Marcel in the midst. This beautiful piece of ironwork is unique in Europe, and well deserving of the attention of artists on account of the elegant forms which have been given to the iron.

The ornament of the 14th century was of a character almost as high as that of the preceding, but the forms had already become less simple and less true, the capitals were divided into stages of foliage, the as-

Fig. 9.



tragals assumed the obtuse angles of the polygon, and the foliage rolled upon itself, gives an appearance of confusion which destroys the general effect. The fleurons which decorate the finials and crocketings are formed of sharp and divided leaves, as thistles and holly, from which there results less severity of appearance in buildings of this age than in those of the foregoing.

In the 15th century great license prevailed in national art; the sculptors gave themselves up to the most vagabond inventions, representing climbing plants of a light form and divided foliage. The vine, thistle, and endive were the most frequent models adopted in buildings of this period, and their use denoted the approach of a revolution. The execution is free, and shows great facility, which they abused, and often to such a degree that their productions are mere

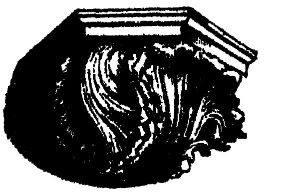
Fig. 12.



From the Chapel of the "Hotel de Cluny."

sketches, touched up with taste. While however we refuse to the decorator of this period the gravity, which characterizes the labours of the two preceding periods, we are obliged to acknowledge that they produced works, remarkable for the luxuriance and variety of their composition, and the effect of the boldness of their undercutting. Towards the end of this century the Revival of ancient art began to take root in the midst of the productions of national medieval art, and again were oriental productions mixed with those of the indigenous Flora. The reign of Louis 12th has left us many monuments of this period of transition, among which the façade of the Chateau de Gaillon, at the Palace of the Fine Arts, deserves to be particularized, as showing the union of the two styles.

Under Francis the 1st, the revolution in art became complete, the ancient style imitated with more or less perfection, sometimes witnessed the introduction of Gothic forms, but always without any disturbing effect. The details of the tomb of Louis the 12th, and the capitals of the Chateau de Madrid, are well enough known to require only to be alluded to. It was under Henry the 2nd, that the Revival arrived at its height. The Louvre, the Chateaux of Anet and Ecouen

Fig. 13.

Bracket for a Lamp, from the Chateau de Gaillon.

and the Tomb of Francis the 1st are monuments perfect in the details of their ornamental sculpture, in which they may contend with classic antiquity, the Revival however was never a servile imitator of the Greek and the Romans. This epoch is particularly remarkable for the composition of capitals and arabesques.

From the reign of Henry the 4th, the Revival begins to lose part of its charm, ornaments became heavy, too numerous, and neglected in their execution, showing how much art had declined.

Under Louis the 13th and 14th, the direction given to ornamental sculpture was in some degree stationary, but at the end of that age, during the Regency and the whole reign of Louis 15th, the decline was rapidly going on. In fact, the corruption of form was such that no epoch in the history of the art has ever produced any thing similar. In the details of the architecture of this period, we witness the complete absence of the observation of nature, which hitherto had always been looked up to as a guide.

Under Louis 16th, it was seen how little this capricious style was adapted to the decoration of severe edifices, and a return to the antique was begun by the architects Soufflot and Servandoni. There were still to be seen however remains of the influence of that bad taste which gave way to the revolution of 1789, and the serious study of the antique which has been pursued in the 19th century.

THE ETCHING CLUB.

This association has been formed by twelve artists (eleven painters and one sculptor), composed of the following gentlemen, whose names will at once be recognized as amongst the most rising of the day:—Redgrave, A.R.A; Webster, A.R.A.; Knight, A.R.A.; Cope, Taylor, Creswick, Horsley, Townsend, Stonhouse, Bell, and F. Stone, with the view of reviving the older excellence of the art of etching, and of conferring upon the popular literature of the country, especially poetry, a more pleasing, original, and artist-like mode of illustration. The first work that they have sent forth, consists of a series of eighty-two illustrations of Goldsmith's exquisite poem, "The Deserted Village. These illustrations, in whatever way regarded, whether for originality of conception, beauty of composition, truth and delicacy of feeling, or correctness of delineation, are worthy of the highest praise. We regret, however, to perceive that the club have adopted the barbarous practice of destroying the plates after taking a certain number of impressions, which, in these days, is quite inexcusable.

FOOT BRIDGE OVER THE RIVER WHITADDER.

Sir—In the number of your Journal for July last, there is a description of a proposed new construction for railway viaducts on the tension bar principle, in which the writer refers to the foot bridge over the river Whitadder, in Berwickshire, on the property of George Turnbull, Esq., of Abbey St. Bathans, as an instance in which the principle he proposes has been applied to bridges. The principle however as adopted at Abbey St. Bathans foot bridge is not carried so far as in the proposed railway viaduct, and as it is simple in its construction, and is found to answer the purpose well, you may consider the accompanying sketch of its details not unworthy of a place in your Journal.

In 1821 Mr. Robert Stevenson of Edinburgh,* designed a bridge for the river Almond, in Edinburghshire, in which the principle of supporting the roadway by iron bars passing underneath was first adopted. This plan however differs from that now in use at Abbey St. Bathans' bridge and elsewhere, as the chains for supporting the roadway are fixed in the abutments, whereas at Abbey St. Bathans the roadway beams themselves are made to resist the strain. Mr. Smith of Deanston, has erected a foot bridge of this kind 103 feet span near Doune.

I am not aware where and by whom the plan of fixing the tension bars to the extremities of the roadway beams was first adopted, but the principle has now come into pretty general use. A beam may in this way be rendered perfectly rigid, and even forced into a slightly arched form, and from the lightness and compactness of the whole it possesses many advantages over the other methods in which the same thing is accomplished.

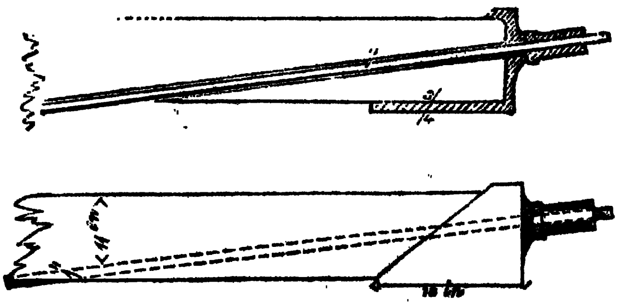
In 1833 a bridge was erected on the tension bar principle over an arm of the Lake of Geneva. It has 13 openings of 55 feet span, and is 25 feet broad. The same plan has been adopted for two foot bridges of 138 and 81 feet span respectively erected several years since over the river Ness, near Inverness, and also for a bridge over the river Whitadder, in Berwickshire, at [illegible] Mill, designed by Mr. Jardine, of Edinburgh, which consists of three openings 50 feet span. Mr. Smith has also applied tension rods very successfully for supporting the floors of the Deanston cotton works, where they have been in use for many years. These, so far as I am aware, are the only instances in which this principle has been adopted.

The Whitadder is subject to heavy floods, especially in the winter season, which interrupts the intercourse between the opposite banks, and as there is no bridge within many miles of Abbey St. Bathans, the want of some means of communication was long felt to be a great inconvenience, and several attempts had been made to build a foot bridge by which the water might be crossed at all times, without having recourse to the inconvenient and often dangerous alternatives of a ferry-boat or a ford; but the heavy floods and ice during the winter destroyed the erections by carrying away the piers.

Messrs. R. Stevenson and Sons, of Edinburgh, being applied to for a design of a bridge, recommended one on the tension bar principle, from its simplicity of construction and the moderate cost at which it might be executed.

The bridge was commenced at the beginning of last summer, and finished in the course of six months. Its total length is 160 feet, and its breadth 4 feet. The planking is 16 feet above the water, which rises 11 feet on the piers during floods, and although the bridge was originally intended for foot passengers only, horses have been occasionally taken across it. It consists, as will be seen from the sketch fig. 1, of two main openings of 60 feet span, and a smaller one of 24 feet span. The beams are supported upon piers of coursed Graywacke rubble. The two in the centre measure 10 feet × 7 feet at the base, and batter to 6 ft. 6 in. × 4 feet at the top. The one which is most exposed to the water is founded upon rock, at the depth of 4 feet under the bed of the river, and the other is founded upon a platform of timber laid on gravel. A causeway of river stones is laid round the base of the piers to protect their foundations from the run of the water. The beams for supporting the roadway planking were made of four pieces of timber for the convenience of getting them readily conveyed across the hills; they measure 11 inches × 6 inches, and are formed of planks of red pine 11 inches × 3 inches. Two of them are 37 feet long, and two 27 feet, so that when put together the scarphs which are 2 ft. 6 in. long occur at different places and exactly over the uprights. The planks are firmly fixed together by means of oaken treenails 3 feet apart, driven right through and wedged at both ends. The ends of the main beams fit into cast iron shoes, as shown in figs. 5 and 6, and the tension rods which go under the beams, and support them by means of the uprights, pass through auger holes in the centre of the beams, and are secured by means of screw nuts 6 inches long to the back part of the iron shoes, as shown in figs. 5 and 6. The diameter of the tension rods is one inch. The screws are used in order to tighten up the rods, which is done until the beams are quite rigid.

Figs. 5 & 6.—Section and side view of the Ends of the Beams.



The main beams and iron work of the bridge were made by Messrs. J. B. Maxton and Co., of Leith Engine-works, and were proved in the work-yard with a weight of one and a half ton, before being sent to their destination. The remainder of the wood work was executed by Mr. Thomas Swan, of Cranshaw.

The entire cost of the bridge was as follows:

Masonwork	£101	7	5
Main beams and iron work	50	0	0
Planking and railing	78	6	0
Forming approaches, &c.	8	5	0
	£237	18	5

I remain, your obedient servant,

John R. Wilson.

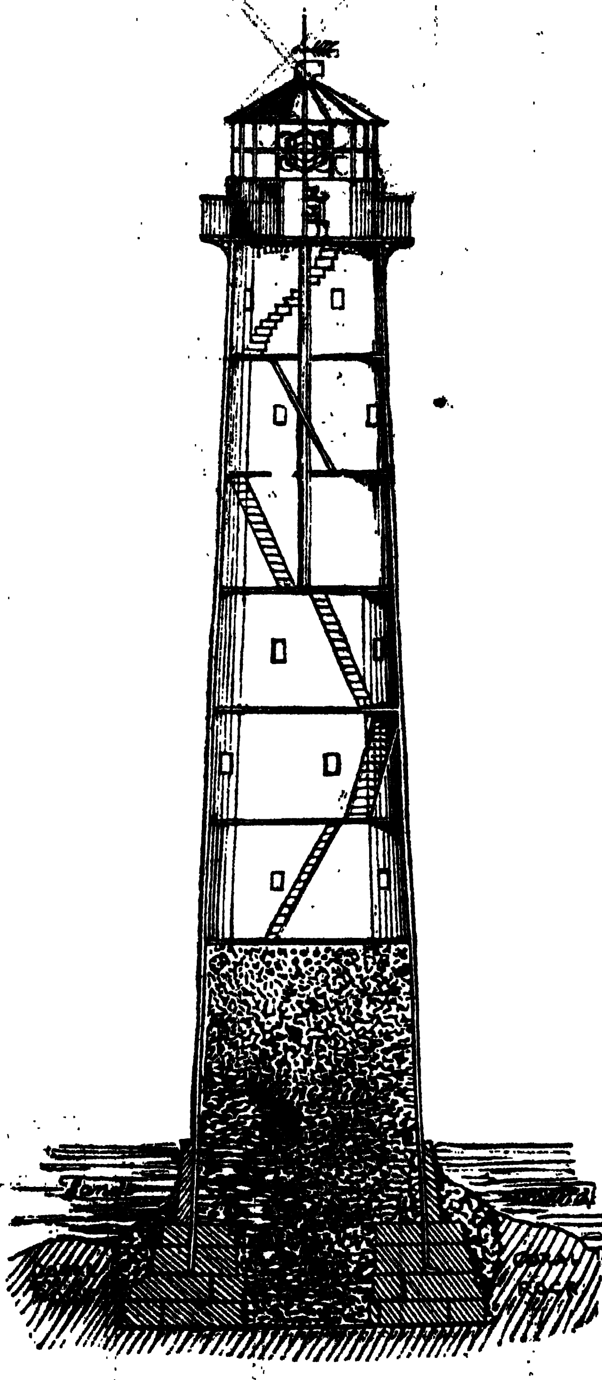
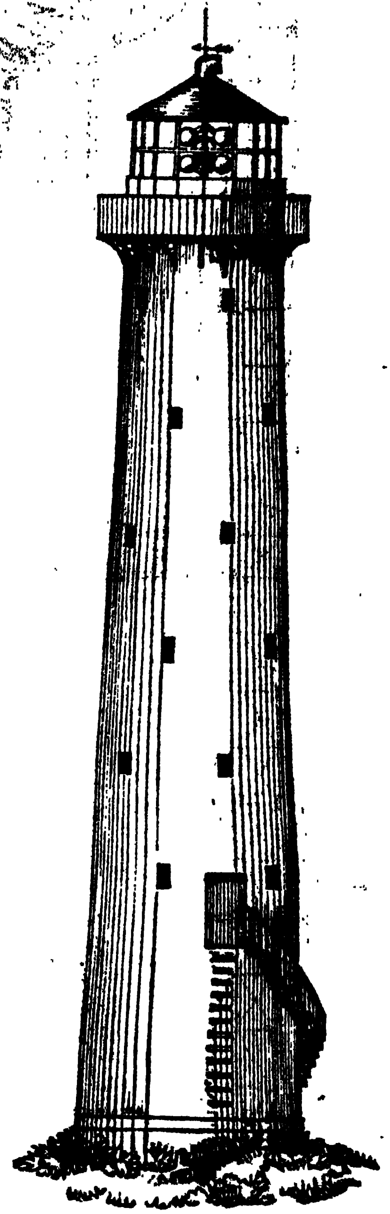
CAST IRON LIGHT-HOUSE,

IN PROGRESS AT MORANT POINT, JAMAICA,

By ALEXANDER GORDON, Engineer to the Commissioners.





In writing a description of a cast iron lighthouse tower just completed for the Island of Jamaica, an opportunity is afforded for a few words on the advantages offered by this peculiar mode of construction. Mariners have frequently been deprived of the security afforded by lighthouses on dangerous coasts, from the great costliness of such structures, as well as from the danger or difficulty attending their erection, in consequence of local peculiarities arising either from tidal restrictions, or from the difficulty of obtaining foundations of sufficient solidity to support the heavy mass of masonry of the tower. It is a fact of common occurrence that years are required to erect a lighthouse of very moderate dimensions where the rate of working is limited, both by the nature of the tides, and by the peculiarity of the season; and the authorities who preside over these matters are frequently deterred from entertaining the application, for such facilities to navigation, from the cost and trouble attending their execution.

The situation for which the lighthouse represented in the accompanying drawings is intended, has long required this protection, but the great expence of stone or brick erection, and the time required to complete them have interfered with their earlier execution to complete the plan.

Mr. Alexander Gordon, the engineer to the Commissioners appointed to carry the plan into effect, is the designer of this building, and who recommended the adoption of cast iron, in consequence of the suggestions some years ago of Captain Sir Samuel Browne, and the subsequent erection of a small light tower on Gravesend Pier, by Mr. Clarke.

The advantages which iron, when not in contact with sea water, possesses over stone or other materials, is, that upon a given base a much larger internal capacity for dwellings and stories can be obtained with equal stability. The nature of the material admitting of the plates being cast in large surfaces, there are fewer joints, and consequently greater solidity. A system of bonding the plates may also be adopted, which will insure the perfect combination of every part, so as to form one entire mass, and by the facility which such a plan offers for uniting the parts, the best form for strength and stability can be obtained. The time required for the construction of such a building in iron being less than that required for the preparation of one of stone, would in many instances influence its adoption, and from the comparatively small bulk and weight of the component parts of the structure, much greater facilities are afforded for transporting and erecting it at its destination. It is a fact worthy of remark that in less than three months from the date of the contract, the lighthouse in question was cast and erected on the contractor's premises, and it is the intention of Mr. Gordon, the engineer, to have the light exhibited in Jamaica, on January 1st, 1842, being six months from the date of its commencement. This is a degree of expedition commensurate with the extraordinary despatch of the present day, when all operations however great and difficult, seem to advance with a celerity which a few years back would have been deemed chimerical.

The expences of the construction, the transmission to its destination, and its final erection, will not exceed one-third the cost of a stone building of equal dimensions and capabilities, and in localities where the materials are not naturally produced, but have to be transported from a distance in a fit state of immediate erection, the expence would considerably exceed this ratio. Another prominent feature in the construction of iron lighthouses, &c. is the security from electric influence, the material itself being one of the best conductors of the electric fluid, and if proper means be taken to transfer the electric fluid from the base of the tower to the sea by means of copper conductors, no danger need be apprehended from its effects.

The lighthouse in question is the first of its kind that has been practically carried out, and from its having to withstand the destructive hurricanes, which, as well as the frequent earthquakes that occur in the West Indies, it will afford a good example for future practice. The form has been selected as well for strength as for symmetry; and the arrangement of the lantern and light apparatus reflects the greatest credit on the manufacturer, Mr. Deville.

The tower is to be founded on a coral rock, a little above the level of the sea, the face of which rock is about 10 feet beneath the surface of the sand, and which will be excavated to receive the base of the tower, resting on and cased with granite, to prevent the natural filtration of the sea water from acting upon the iron. The course of granite upon which the base of the tower rests, is grooved to receive the flange of the lower plates, from which the lightning conductors are continued to the sea. The diameter of the tower shaft is 18 ft. 6 in. at its base, diminishing to 11 feet under the cap; it is formed of nine tiers of plates, each 10 feet in height, varying from 1 to ¾ inch thickness. The circumference is formed of 11 plates at the base, and nine at the top, they are cast with a flange all round the inner edges, and when put together these flanges form the joints which are fastened together with nut and screw bolts, and caulked with iron cement. The cap consists of 10 radiating plates which form the floor of the light room, and secured to the tower upon 20 pierced brackets, being finished by a light iron railing. The lower portion, namely 27 feet, is filled up with masonry and concrete, weighing about 300 tons, and so connected with the rock itself that it forms a solid core of resistance; the remaining portion of the building is divided into rooms which are to be appropriated as store rooms and berths for the attendants in the lighthouse.

The light room consists of cast iron plates 5 feet high, on which are fixed the metal sash bars for receiving the plate glass, these terminating in a point are covered with a copper roof, from which rises a short lightning rod, treble gilt at the point, to attract the electric current.

The light is of the revolving kind, consisting of 15 Argand lamps and reflectors, 5 in each side of an equilateral triangle, and so placed as to constitute a continuous light, but with periodical flashes.

In order to preserve as low a temperature as the nature of the circumstances and climate will permit, the iron shell is to be lined with a non-conducting material, such as slate or wood, leaving an annular interstice, through which a constant ventilation will be effected, and by which the excessive heat will be carried off, or which it will doubtless be assisted by the evaporation of the sea spray which may accidentally be cast upon it, as it will be placed within 60 yards of the ordinary water level.

In order to preserve the two lower tiers from oxydation, they have been coated with coal tar, and Mr. Gordon intends to set them in the granite with a bituminous cement. The only bracing which has been thought requisite is a few cross ties at each horizontal joint, over which the iron tongued wood floors are laid.

The several rooms are provided with five apertures fitted with oak sashes glazed with plate glass; the approach to the doorway which is about 10 feet above the level of the sand, will be by means of stone steps, ladder irons are also provided in the event of the stone steps being carried away by a hurricane.

Over the entrance is a large tablet of iron, supported by two small ones, and on them, in bas relief, are the following inscriptions:—

"Erected A. D. 1842,
"Under the act 3 Victoria, cap. 66.
"Commissioners.

"Vice-Admiral Sir Charles Adam, K.C.B.	"E. Jordan, Esq.
	"P. Lawrence, Esq.
"Commodore Douglas, R.N.	"Hon. T. M'Cormack.
"Hon. S. J. Dallas.	"Hon. E. Panton, Speaker.
"W. Hyslop, Esq.	"A. Barclay, Esq.
"J. Taylor, Esq.	"H. Leslie, Esq.
"Hon. H. Mitchell.	"G. Wright, Esq.

"On the designs and specification of Alexander Gordon, civil engineer, London."

And on the side supporters:—

"Captain St. John, R.A., Island Engineer."	"C. Robinson, Engineer, London, *fecit*."

The whole of the castings were executed by Mr. Robinson at his manufactory, (late Bramah and Robinson), at Pimlico, and put together in the yard of the manufactory prior to their removal for its intended destination.

The work will be re-erected in Jamaica by means of a derrick and crab from the inside, without the aid of any external scaffolding.

Arch. R. Renton.

September 22, 1841.

[We understand that the whole expence of the lighthouse, including the passage over the Atlantic, and the erecting it on the promontory in Jamaica, will not exceed £7000, and that the entire weight of iron of the whole fabric is about 100 tons. The masonry is being prepared in this country, as it will be more economical to send it from England than it will be to get the stone and work it in Jamaica. Three mechanics are also to be sent out with the work to put it together on its destined spot.—Editor.]

TURKEY.

The spirit of improvement which has been of late years exhibited by the Turkish government has not been confined to political and social reforms, but has also been directed to objects of a practical nature. In aid of these efforts frequent calls have been made on the talents of our engineers, and some very fine machinery indeed has been sent out to Constantinople. Much of this has been on a very large scale, and we may enumerate saw mills, musket machinery, and gun-boring machinery. The machinery supplied by Messrs. Maudslays for boring brass guns, said to be the finest and most extensive of any in the world, has given great satisfaction. The same firm have lately finished an order for mint machinery, also on a large scale, which has excited great commendation from the completeness of its design, and the beauty of its execution. It consists of two 16 horse power high pressure engines, two pair of large rollers, and two pair of smaller rollers, six cutting out presses, two double draw benches, four coining presses with pneumatic apparatus, and a die sinking press, with two double acting milling machines, ingot moulds, &c. To those who admire this class of machinery, as who does not, the examination of this minting apparatus was highly interesting, uniting as it did all the recent improvements which have been adopted in our mint. The Turkish dockyard it must be further remembered, is directed by an Anglo-American, and is in a very efficient state, and the public at Constantinople have recently been turning their attention towards steam navigation, so that we may look forward for a new market for our machinery in the Turkish empire. To the engineering and mining interests the progress of this increasing branch of our commerce is of great importance.

IMPROVED CONSTRUCTION OF PISTONS AND VALVES, FOR RETAINING OR DISCHARGING LIQUIDS, &c.

Patented by Messrs. G. H. Palmer and Charles Perkins.

Fig. 1.

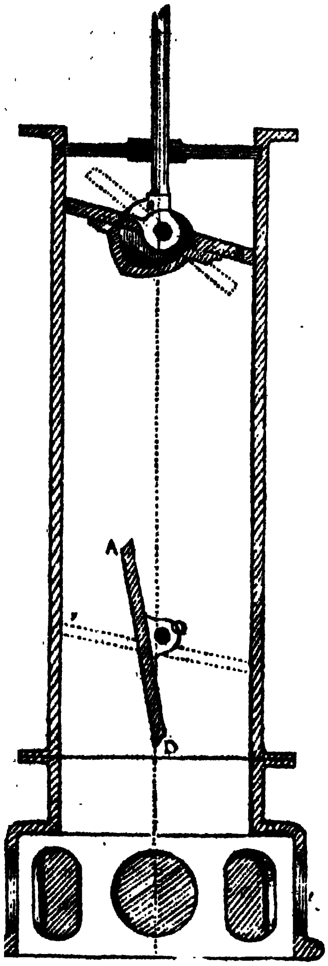


Fig. 2.

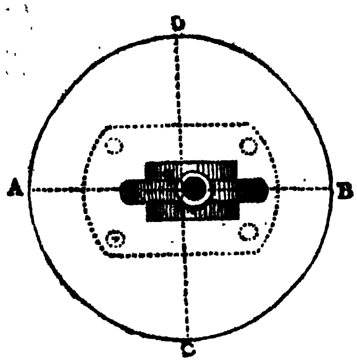

Fig. 3.

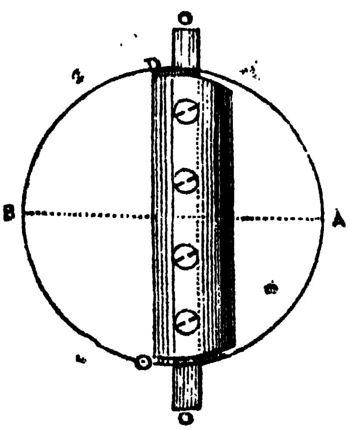

Fig. 5.

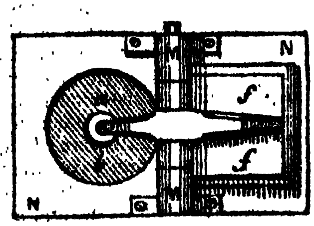

Fig. 4.

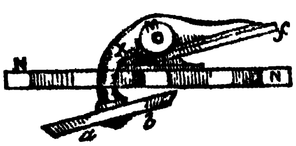

Fig. 1, is a plan of the piston, a section of which is shown by fig. 3. A B the major, C D the minor diameter; the joint (by which the pump rod is secured), is in the centre of the true line of the major diameter A B, but neither in the centre of the pump or piston, being removed therefrom more or less as the diameter of the pump, the altitude of the column of water lifted, and other circumstances may require. The whole area of the piston is therefore divided into two unequal areas.

Fig. 2, is a plan of the lower valve, which is fixed in the barrel by means of the axle O, the eccentricity of which is regulated upon the same principle as that of the joint in the upper valve or piston.

Fig. 3, shows the relative position of the piston and valve during the upward or effective stroke. The dotted lines show the position of the valves in the downward or return stroke.

Figs. 4 and 5, are a plan and section of a patent double balancing valve, an application of the same principle as adapted for safety, or any valves connected with steam engines or air pumps, also to lock gates or sluices, and generally as a simple and effective mode of retaining or discharging liquids, gases and steam. The two valves being of unequal, but the inner of the greater area, and the pressure upon both, being in the same line of direction, it is evident that the power to open or shut them may be determined at pleasure by regulating the difference between the two areas, *a b* is the larger, and *f f* the valve of smaller area, each of which are connected with, and works upon, the axle M M, supported by carriages on the valve bed N N. The valves *a b* and *f f*, receive simultaneous action by means of the curved lever or tail piece X.

The patentees recommend the adoption of the patent elliptic self adjusting balancing pistons in all pumps for whatever purposes intended, as the most simple, durable and effective of any arrangement now before the public. Simple, as is evident from the diagrams and description herewith. Durable, because the process of raising water from any depth is performed by two metallic discs, not liable to derangement, and free from most casualties of climate, circumstance, or wear. Effective, first, because a very superior water way is obtained, (there are no valves to clog or gag, no resting place for any extraneous matter to impede the duty of the pump, whether it be sand or rubbish). Secondly, it will remove the evil arising from concussion in pumps of large diameter; and thirdly, in consequence of the decreased amount of friction, the service of a man in pumping is increased in the ratio of nearly 3 to 1, as the following statement will demonstrate.

The patentees have two 10 inch pumps, the levers 6 to 1, the stroke 8 inches, the column of water 5 feet; both pumps were made by Messrs. Bramah and Robinson, in their best manner; alike in all respects, except that one is fitted with the usual packed bucket and butterfly valves, the other with the patent piston and valve. In an experiment recently made with weights over a pulley, it required the exertion of a force equivalent to 461 lb. to raise and deliver the water, (about 2 gallons), and return the bucket with the packed pump, and only 196 lb. to do the same work with the patent pump; making the labour to work the two pumps in the ratio of 461 to 196 = 23 to 10.

Another experiment was made for the patentees by Mr. Beale, of Greenwich, showing similar advantages in the diminution of friction, and consequently an increase power. The following is the result of this experiment.

A vessel of a capacity equal to 314·16 gallons = 3141 lb. was filled by pumping 140 strokes in 4½ minutes, which was at the rate of 31 strokes per minute, and 2·244 gallons per stroke. The working barrel of the pump was intended to be 10″, but was said to have been turned to 10¼ inches nearly.

If the diameter was 10, then the delivery by computation in 140 strokes of 8″ = - - - -	318 gallons.
If the diameter was 10¼, then the delivery = - -	330
The actual delivery was by computation of the receiving vessel = - - - - - - -	314

The average lift during this time was about six feet.

In a second experiment the water in the well was kept at an average height which, with pipes added to the exit pipe, made the total lift 15 feet 4 inches.

Under these circumstances weights were applied to the end of the lever, and it took 98 lb. × 6 the leverage to raise the column of water.

Now 98 × 6 = - - - - - - - - - -	588 lb.
The actual weight of a column of water 10¼″ diameter and 15 feet 4 inches in height, is - - - - - -	550 lb.
Leaving for friction in the up stroke only - - -	38 lb.

As there was no friction in the down stroke or return of the piston, it results that 38 lb. was the total amount of friction out of 588 lb. (exerted), being only 6·46 per cent. or $\frac{1}{15}$ part.

The velocity of the water may be taken at 20 feet per minute.

In a third experiment, to produce a *maximum* effect, two men made 41 strokes in one minute, lifting the water 15 feet 4 inches, and delivering as per first experiment 2·241 gallons, or 22·44 lb. per stroke = to 14107·28 lb. raised one foot high in one minute by two men, or 7053·64 lb. raised one foot high in one minute by *one* man.

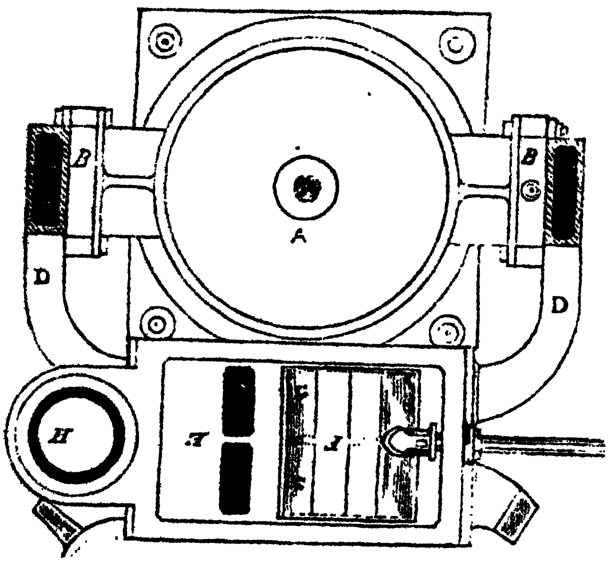
Artificial Ice.—The projectors of the artificial ice plan have found a site in the New Road, opposite Lord's cricket ground. We have seen the composition, which seems to succeed, and the plan is approved by the Skating Club.

ON REVERSING OF ENGINES.

Sir,—When we look to the methods of reversing the motion of reciprocating steam engines which have hitherto been generally adopted, it becomes a matter of surprise that, whilst in almost all patents for rotary engines, where it has been considered the motion would want reversing, it has been done on the principle of changing the steam induction and eduction passages, (*i. e.* what is the induction for one way is made the eduction the other, and *vice versâ*), the same principle has not been adopted for them. The most general and simple way of changing the passages in rotary engines has been by means of the common slide valve, and my object in now addressing you is to propose the adoption of the same slide valve to the reciprocating engine.

The accompanying figures represent it as applied to a pair of marine engines, for which it seems particularly suited. Let A in the figures represent the cylinder; B B B B, valve boxes fitted with stop valves *v v v v*, almost similar to those of Messrs. Seaward's patent, except that both the valves and boxes are faced on both sides; C 1, C 2, communication pipes to each pair of boxes; D D, branch pipes from C 2, C 1, to the apertures in the slide valve box E; being alternately steam and exhaust as their respective apertures may be covered by the slide valve F; G is the exhaust or eduction to the condenser; H the induction or steam-pipe from the boiler. The valves strike simultaneously (as Seaward's), and are like them worked by one fast eccentric.

Fig. 1.—Plan of Cylinder.



It will be seen as the valves stand in the figures that the steam passing down H into the valve box E, and down the uncovered apertures to communicating pipe C 1, finds the upper aperture stopped up, it consequently makes its way through the lower one and forces up the piston, at the same time the upper valve on the other side of the cylinder is open, and a vacuum being formed in the condenser, it exhausts G, under F, the branch to and the communicating pipe C 2, and the portion of the cylinder above the piston.

If we wish now to reverse the motion, we have only to push the valve F to the other end of the box, as represented by dotted lines in fig. 3, the branch pipe, and C 1 is open to the condenser, and the steam passes down the branch into C 2, and presses down the piston.

The mode of operation will I think be now understood. Fig. 4 is a view of the valve F, as proposed for a pair of engines, showing the midfeather to separate the exhausts or eductions to the respective condensers. The branch pipes to the other cylinder are shown broken off. There is another use of the valve F, it is a perfect regulator or throttle valve, to stop or regulate the engine by; for it is so constructed that supposing the steam to be shut off by it when running either way, still the exhaust apertures remain entirely open. The simplicity of its action, and its doing away with a considerable number of small moving parts consequent on reversing and management in general, by the present methods are its recommendations, not to mention that one man could manage a pair of the largest engines which have yet navigated the ocean, better than 4 or 6, or even 10 men, to some of our present large marine engines. I have a sketch by me, only in pencil as yet, for working locomotives by the same principle, but being so confined as to space, little difficulties present themselves in the arrangement, which a more practical man might soon set aside.

Fig. 2.—Section of Cylinder.

CANDIDUS'S NOTE-BOOK.

FASCICULUS XXXI.

"I must have liberty
Withal, as large a charter as the winds,
To blow on whom I please."

I. Those who rail against competition, not because competitions are for the most part vilely conducted—most bunglingly also, supposing there to be honesty of intention, or else most fraudulently, as there is frequently good reason to suspect, perhaps all but positive evidence to prove—the declaimers against competition, carefully keep out of sight the mischiefs that have been produced by non-competition. It is impossible to believe that Buckingham Palace would have been the miserable architectural abortion it now is, an object of shame to Englishmen, and of contempt to foreigners, had others been allowed to measure their talents with those of John Nash. In such case an open competition might not have been at all advisable, but a middle course might have been pursued, and a certain number of those of most likelihood in the profession should have been invited to send in designs, and every set of drawings should have been paid for except those by the successful architect, who would be amply remunerated otherwise. A thousand pounds a-piece would not, perhaps, have been at all too much: while it would have been sufficient to induce those selected as competitors to exert themselves heartily, it would not have been an extravagant reward, considering the study such a subject would have required, the expenses the competitors must have incurred, and the other engagements they must have neglected or postponed. Supposing the number of competitors had been ten—it might have been fewer, the £9,000 would not have been recklessly squandered. Even supposing the result had been precisely the same as at present, we should at least have had the satisfaction of knowing that the bauble we have now got was the very best thing of its kind that was to be had. As it is, there was the saving of a few thousands in the first instance, and we have got John Nash's chef-d'œuvre—no very great bargain after all, any way, when we take into account the tens of thousands expended in pulling down and re-building, while it was in progress, and afterwards in botching it up and licking it into shape.

II. The anti-competitionists would do well to consider what sort of design we should have had for the new Houses of Parliament, had there been no competition, but a Nash, a Soane, or a Smirke, been called in, and left to do his best or his worst, and to go on as he pleased without further inquiry. Without much fear of contradiction, it may be affirmed that had there been a competition for the National Gallery, we should have had something better rather than worse than the present structure; and the same may be said in regard to a great many other buildings. Of course it must be assumed that the competition is fairly managed, and that there be not only perfect fairness, but the requisite taste and judgment also. It is no satisfaction to be assured that the decision has been made to the best of their ability by those with whom it rested, if the choice itself convicts them of utter inability and incapacity for such office. If associated with bad taste, honesty may do more harm than good in such matters; yet as far as honesty is concerned, there is very little danger of any mischievous consequences from excess of it, at least not just now, for, if reports may be credited, some very ugly instances of thorough-paced roguery and rascality in the management of competitions, have recently taken place.

III. If no other, there is at least one remarkable peculiarity attending architectural criticism, viz. that so far from endeavouring to be *au courant du jour*, it generally lags most wofully behind-hand, as if it were almost a positive breach of decorum, to discuss the merits of productions belonging to our own times. Why it should be considered requisite to exercise such forbearance towards living architects and their works, more especially, the very reverse of it being frequently manifested in the case of literary men, actors, artists, &c., it is difficult to understand. Neither is such over-delicacy particularly complimentary, since it almost amounts to a confession that it is impossible to speak honestly of the living without also speaking harshly, therefore the critic who would neither give offence nor compromise his own judgment, has no other alternative than silence. On the other hand, however, Brummagem criticism and puffery are allowed to circulate freely enough; for though delicacy may withhold some from giving their opinion unreservedly in the case of architects either living or recently deceased, many there are who do not scruple to cry up almost every thing as a wonder of its kind. With them every goose is a swan, or rather a phœnix. Whatever they are speaking of is, for the time being, superlative of its kind. Their chief merit is their impartiality, since they treat all alike, making no distinction between a Charles Barry and a Richard Brown. Yes, incredible as it may seem, even Professor Brown has his admirers; not long ago a flaring-up puff appeared in a weekly paper on the Professor's "Domestic Architecture," bearing testimony to the value of the work, and the varied talent displayed in the designs, "which would afford to the student examples in every style of building"! Thus a publication which is absolutely pestiferous in taste, and as far as it circulates, is calculated to spread the most vulgar taste throughout the land, not only escapes reprobation, but is actually recommended as an authority and a trustworthy guide. Pity it is that Pugin did not show up some specimens of his brother Professor's designs along with "castellated" firegrates, and similar monstrosities. Should Welby not be yet aware of the existence of Brown's publication, we earnestly recommend it to *him*, for he will find in it some exceedingly piquant tid-bits, *inter alia*, a sample of Egyptian that might very well pass for one of the plagues of Egypt.

IV. Want of keeping is so exceedingly prevalent a fault in architectural design, that it would seem to be the most excusable of any, as being of all others, the one most difficult to be avoided, whereas I should decide precisely the reverse, it being, in my own opinion, one of the most offensive and the least venial, because that which argues the absence of artistical feeling. In every composition there ought to be some leading features, and some parts of a building will very properly bear to be more ornamented than the rest; yet this should be so managed that the *ensemble* shall appear consistent, and the whole design all of a piece as to taste. Look at the Post Office—there are Ionic columns, but the structure itself is absolutely dowdy in its style. Look at the Post Office, Dublin—there we have another large Grecian Ionic portico attached to a very plain and ordinary house-front. Look at Goldsmith's Hall—the lower half of the design is altogether different and distinct in character from the upper one. Look again at Lord Sefton's new mansion in Belgrave Square—within a carriage porch of the very plainest Italian Doric possible, is a doorway of unusually rich design, which, in such situation, looks as much overdressed in itself, as it causes the columns and their entablature to look plain, even to the appearance of being unfinished. In a new house near Park Lane, I observe there is some approach to the Italian style, the elevation being crowned by a cornice somewhat bolder and richer than usual; but the windows!—they are in the modern Pseudo-Grecian fashion, with no other dressings than architraves, and those of the very plainest description. In all such cases it looks as if the architect had been obliged to pare down his design in order to save expense, and that, instead of simplifying it consistently throughout, he had merely omitted in execution that decoration which was in the first instance proposed as essential to unity of expression.

V. Another great and pervading vice in modern design is that so little regard is had to the sound and legitimate principle of commencing decoration by first applying it to essential features—those arising out of construction, or required by utility and convenience, instead of introducing what is merely for embellishment, while other things that cannot possibly be omitted or got rid of, are left not only plain, but quite rude in appearance, so as to become, by contrast, positive eyesores. That such errors in taste—such violation of all artistic principles of composition, should ever be committed, is grievous enough, but that it should be committed so very frequently, and by those who are so fastidious and puritanically pedantic in regard to matters of infinitely less importance, is most grievous and most provoking. Utility and beauty ought to go hand in hand, but should be made to do so after a very different fashion from what is now generally the case, when one half of a design aims at nothing more than unadorned usefulness, and the other at ostentatious show. Their usefulness does not reconcile us to ugly chimneys and chimney-pots confusedly huddled together on the roof of a building—to bare openings for windows, or else having only some scanty common-place mouldings bestowed on them,—to insignificance and vulgarity as regards matters of that kind, while unnecessary and inconsistent, therefore absurd parade is indulged in as regards others. One ill consequence of such unfortunate system is that people are satisfied with mere shreds and patches of design, and think it quite enough if they are able to say such or such a part is very good, though the general effect may nevertheless be poor in the extreme, and the whole no better than a jumble of the most incoherent and contradictory members.

Progress of Steam.—We learn that in a short time the merchants of St Petersburgh will have a direct line of steam communication, via the North of Germany, Yarmouth, and this city, with New York.—*Bristol Standard.*

ARCHITECTURE AS A FINE ART: ITS STATE AND PROSPECTS IN ENGLAND.

By George Godwin, Jun., F.R.S.

> "That art where most magnificent appears
> The little builder, man."

"I shall not neede (like the most part of writers) to celebrate the subject which I deliver. In that point I am at ease. For architecture can want no commendation, where there are noble men and noble mindes." So wrote Sir Henry Wotton more than two hundred years ago, with reference merely to the Roman style, when classic architecture was but beginning to revive:—before Inigo Jones and Sir Christopher Wren had nationalized it amongst us, or Lord Burlington's example and endeavours, had made a smattering of its principles almost a necessity of fashion. Since then, the treasures of Greece have been ransacked and sent home to us to correct our taste and aid the study; the claims of middle-age architecture to be regarded as the work of supreme genius have been admitted universally, (its intrinsic beauty, the extraordinary skill displayed in its development, its power of inducing

> "A stir of mind too natural to deceive;
> Giving the memory help when she would weave
> A crown for Hope!"

have all been felt,) and delineations of its choicest specimens in a thousand and one books have been dispersed amongst us to render its details more known, and its imitation less difficult.

The history of architecture has been written,—the beautiful relationship of the various styles has been shown, (each growing out of and in its turn producing,—) forming a narrative most interesting and striking to all who look not carelessly on the progress of the human family, and sufficient it might be thought, to arrest and retain the attention of all readers. The history of our ancient buildings is more fully felt to be inseparably connected with the history of our country,—every old stone in England is known to tell a story, and therefore should have now a firmer hold upon the people than then, and yet we doubt whether any might venture to repeat at this time Sir Henry Wotton's remark which we have quoted. Certain it is that many "noble men" care nothing about architecture, and that many more "noble mindes" seem to require it should have very much "commendation" before they will be induced to give attention to it.

The degree of ignorance on the subject of architecture to be found amongst persons in other respects not merely well informed, but even learned, is quite extraordinary. Grecian, Roman, Gothic, Elizabethan, as applied to architectural style, are to them but words without any corresponding ideas; they have never considered that architecture has a chronology, still less, a philosophy,—architectural integrity, harmony, proportion, fitness, are to them foreign things,—in fact, beyond a notion that architecture means piling one stone upon another, and forming places to live or meet in, they know nothing and care less.

Great part of this inattention on the part of the multitude to the interesting and noble study under notice, (and of which the results whether for good or ill, usually endure long, and are constantly before the eyes of all,) has been justly ascribed to the connection which exists in the public mind between architecture as a constructive *science*, and architecture as a *fine-art*, and every endeavour ought therefore to be made to enforce a knowledge of this difference on general readers, and to point out to them how large a source of fresh delight would be opened to them by its study in the latter point of view. The pleasure of travel is trebled by it. Proofs in aid of former studies, objects for investigation, incentives to inquiry, arise on all sides; tongues are literally found in stones, and a habit is acquired of weighing causes, and testing by judgment whatever is brought before the mind, which is of the greatest value, not merely in this particular case but in all the affairs of life.

For the sake of example, but briefly, let a man possessed of its history, and imbued in some degree with its principles, visit, in company with one entirely ignorant of both, an old town, or be set down before a new building. In the first, he might perhaps find a massive piece of walling, formed of beach-stones imbedded solidly with mortar, and bound together at certain distances in its height, by layers of long thin bricks almost resembling tiles. This he would at once recognise as a remnant of the work of that period when the Romans brought, though as conquerors, the arts to England, and laid the foundation for after-elevation and prosperity. Britain and its skin-clad inhabitants, the invasion of Cæsar, the downfall of Rome, the invitation to the Saxons would be the concomitant remembrances.

One of the gateways leading into the cathedral-close—which we will suppose the town to possess, might present semi-circular arches springing from small columns, and ornamented on the face with a rude zig-zag moulding, or a series of birds' beaks, which he would know to be the design of some of those Norman architects who, after the conquest of England by Duke William, employed themselves actively for some time, in covering the land with donjons and churches. The abasement of the Saxons, the curfew, forest laws, the feudal system generally, would pass involuntarily through his mind, and afford matter for long and pleasant reflection.

The cathedral itself would perhaps display in part, the feathery lightness of the pointed style of architecture with lofty arches, pinnacles and buttresses, intermixed with work of later date, shewing arches almost flat, superfluity of adornment, and the decay of taste: all which would be sufficient not merely to recall to the initiated beholder the changes which took place in architecture during two or three hundred years, and ended in the importation of a style from Italy, in the reign of Charles I, or a little earlier, and a contemptuous disregard of the beautiful structures before spoken of, and then first termed *Gothic*, in derision,—but would bring before him the progress of Christianity, the power attained by the clergy, and the state of the country and the people, in a variety of fresh phases.

At the new structure again, he would perhaps see the clever adaptation of means to an end, and proportions well preserved; read in its architectural expression an accordance or otherwise, as the case might be, with its purpose; and study the causes which conduced to render the effect of the whole on the mind satisfactory and pleasing. Thus would the imagination of the one be gratified, his judgment strengthened, his sagacity increased, while the second, who had given no thought to the subject, and had gained no information upon it, would necessarily be blind to it all, or seeing, would understand not.

The analysis of the causes of beauty in works of architecture, is certainly far from an easy task; it yet remains for some powerful mind keenly perceptive and nicely discriminating to deduce a code of laws or principles to be universally applicable in this inquiry. Whether however, this is likely soon to be effected, or that these subtle properties will continue to evade reduction to general rules, it is difficult to say. At present we must be contented to apply in individual cases, a number of unconnected canons, and to investigate the particular results of certain arrangements of form, compliance with prejudices, or the production of novelty.

"The art which we profess," says Sir Joshua Reynolds, speaking of painting, "has beauty for its object; this it is our business to discover and to express; the beauty of which we are in quest is general and intellectual; it is an idea that subsists only in the mind; the sight never beheld it, nor has the hand expressed it; it is an idea residing in the breast of the artist, which he is always labouring to impart, and which he dies at last without imparting—but which he is yet so far able to communicate, as to raise the thoughts and extend the views of the spectator; and which by a succession of art, may be so far diffused that its effects may extend themselves imperceptibly into public benefits, and be among the means of bestowing on whole nations refinement of taste." Now in architecture, which is not an imitative art, but one of imagination and adaptation, if we may so speak, (born of necessity,) there are two other objects to be attained, namely, commodiousness, (or fitness for the purpose,) and stability: in reference to both of which, although perhaps it is not for these it is entitled to the appellation of a fine art, the claims of a building to perfect admiration must be tried. It seems clear that these qualities may exist without the production of beauty, even with *proportion* of the parts superadded,—(a word by the way the meaning of which is any thing but precise, as what is deemed proportion under some circumstances, or in one place, is not so in others;) but the production of beauty which will satisfy the mind can hardly be hoped for without minute attention to all these points. Variety and intricacy, with yet a prevailing uniformity, may be regarded as important in the production of pleasure in the spectator:—in so far as while the mind is able at once to comprehend and dwell upon the unity of the whole, it may be interested in the novelty or propriety of each detail, and find delight in this indication of the energy, ingenuity, and power displayed in its formation. We must not however here venture on an inquiry, which interesting as it may be, is beyond the intention of the present paper.

To return, then, to our former subject. The neglect which architecture has experienced at our universities (as, indeed, have all the arts), is another plainly apparent cause of the ignorance complained of, and it is gratifying to see indications, although but partial, of the presence of a different spirit amongst the members of the universities, if not in the universities themselves. Oxford and Cambridge both have now societies for the study of Gothic architecture, and for the purpose of aiding in the proper restoration of old buildings. Many papers of great merit have been read at both, and numbers of [illegible] have been composed, classified in such a manner as to aid materially in impressing on those who will study them, the peculiarities and characteristics of the various eras in architectural history. In Bristol a similar society has been formed recently, and it is to be hoped that the example will be extensively followed throughout England.

Among the important advantages, not before alluded to, as certain to arise from the spread of architectural knowledge, would be an almost immediate improvement in the professors of the art themselves. Improve the capacity of the judges, raise the ordinary standard of taste, create a demand for superior skill, and the result inevitably must be that individuals will be found capable of supplying it, and that fine works will be produced.

The association of architects not merely for the study of their profession and the interchange of opinions and kindly feelings, but with a view to popularize their art, and by spreading abroad their Transactions, and inviting strangers to their meetings and *conversazioni* to render it matter of general interest, must be regarded as likely to assist greatly in removing the ignorance complained of. The Royal Institute of British Architects, a chartered body, including in its list of members the greater number of the heads of the profession, in correspondence with most of the continental states, and presided over by one of the most accomplished noblemen of the day, may be considered as the chief of these associations, and has it in its power to influence the age very materially—more so indeed than it has yet attempted to do. The publication of a volume of its transactions, at least annually, should be regarded by the members as most important, while, to make these transactions valuable and effective, should be the constant study of all who are connected with the Institute, or wish well to their art.* The London Architectural Society, the Institute of Irish Architects, and the Manchester Architectural Society, are all influential bodies of a like character, and are called on to exert efficiently the power which is in their hands.

At the Royal Academy, where of late years an inexcusable degree of inattention to architecture has been manifested, affairs are wearing a more promising aspect. The present accomplished professor, Mr. Cockerell, has entered on his duties with singular and praiseworthy zeal, and eminent as he is for a love of his art and desire to spread a knowledge of it, will not fail to pursue them energetically in a right course. The establishment of schools of design throughout the country (in the arrangement of which Mr. Cockerell has taken active part, as also did Mr. J. B. Papworth,) will be of great service to architecture, by increasing the number of those able to carry out effectively the designs of architects, while, by imbuing artizans with an artistical feeling, they will serve materially to raise their callings in the scale of society. How greatly the architects of the middle ages were indebted to the ability and feeling of their operatives is too well known to need notice here.

The want of information, and the low state of architectural taste, which have been complained of as still existing, have been strikingly exemplified in the results of many competitions for designs which have been brought before the public within the last ten years. The insufficient particulars and instructions given to architects, the want of courtesy displayed towards them, and the ultimate unjust decisions, have proceeded in as many cases from entire ignorance, with a wish to act rightly, as they have from underhand influences and bad motives. And until we can in some degree remove these first-mentioned evils, we can hardly hope, however much we may strive, to prevent this injurious result, injurious not less to the public than to the artists and art itself. That artistical competitions, by affording opportunities for the encouragement of unaided merit, by preventing professors of established practice from falling into a routine habit of composition, and by inducing young men to study subjects which otherwise might not come under their notice—are advantageous, is the opinion of the great majority of those who have thought upon the matter. We would go so far as to say that for *all* works entitled by their destination or importance to be called national, the nation should unquestionably be appealed to, and opportunity thus given for unknown talent to come forward.

Brunelleschi, Michael Angelo, Palladio, Fontana, Scamozzi, are all to be found in the list of those who competed for the honour of conducting important works in Italy. In England, however, until the decision in these matters can be more depended on than now, (when, in fact, the administration of every succeeding competition is worse than that which preceded it,) men of integrity and ability who have reputation to lose, will not enter the lists except in special cases, and the result must be that the field will be left chiefly to unemployed tyros or manœuvring traders.

If we be correct in our opinion, that until information be spread and the taste of the multitude be improved, we cannot expect to effect much alteration, it is to this end surely we should apply all our efforts, vigorously and unceasingly. Why should not architecture and the other fine arts be taught universally in our schools, and be made a necessary part of a liberal education? At all events, professorships should unquestionably be instituted at the universities, to spread a knowledge of the beautiful, and inculcate a love for it. Every day is science exerting its powerful influence to liberate men from the necessity of manual labour. Every day, therefore, does it become more and more necessary that unemployed minds should be put in the right track, that intellectual and moral wants should be created, and that all means be taken to elevate the taste of the multitude, and supply their cravings for excitement with proper *pabulum*.

To improve a love of the fine arts amongst a people, not irrespective of RELIGION, but in connexion with it, must be regarded by all wise and enlightened statesmen as an object of paramount importance, to be attained almost at any price.

* If a monthly *bulletin* were issued in a cheap form, containing an abstract of each night's proceedings, it would be of much service. Unconnected items of information elicited in conversation, and papers not sufficiently important to appear in the "Transactions," might therein be recorded. Information would thus be spread, and there would be an additional motive for members to communicate matters which, though trifling in themselves, might be important in the aggregate. Besides, the more the fine arts are talked about and written about—the oftener they are brought under public notice, the more likely is it they will receive general attention. The public require a thing to be said a great number of times, and in a great many ways, before they will heed it.

ENGINEERING WORKS OF THE ANCIENTS, No. 9.

IN our present paper we conclude our extracts from Strabo.

THE GREEKS.

The silver mines of Attica (Book 9, chap. 1), were formerly very productive, they are now exhausted. When they still produced a slight return for the labour of the miners, they melted up the old rubbish and scoriæ, and a considerable quantity of very pure silver was obtained from them, seeing that the ancients were not very skilful in the art of extracting metal. A commentator remarks on this passage that it is a proof of the progress of mining in this age, but that even then the Romans had been by no means gone to the extent of modern art, as sufficient is still sometimes found in Romish scoriæ to pay for the expense of extraction. He farther observes that the mines of Laurium showed signs of exhaustion in the time of Socrates (Xenophon Memorabilia, book 3, chap. 6, § 12.)

In the next page Strabo notices a bridge over the Cephissus.

In book 9, chap. 2, our author gives a description of the works on the Euripus, but one which is very inaccurate.

Speaking of the plains of Beotia opposite to Eubea (book 9, chap. 2), an account is given of the works undertaken to drain them by a contractor for works of the name of Crates of Chalcis. He was obstructed by the factions among the Beotians, but in a report, addressed by him to Alexander, he relates that he had already drained several large tracts. This contractor is also mentioned by Diogenes Laertius, book 4, § 23, as being employed by Alexander.

In book 10, chap. 1, is an obscure passage relative to the mines of Chalcis.

In the same, chap. 3, Strabo refers to the labours of Hercules on the Achelous.

The Rhodians as well as the Cyzicans and Marseillese were famous as military engineers (book 14, chap. 2.)

CILICIA.

Book 12, chap. 1, contains an account of the mode in which King Ariarathes the 10th stopped up the Melas, a feeder of the Euphrates, and how the dike having burst and caused injury to the neighbouring lands, the king was fined 300 talents by the Romans.

PONTUS.

Chapter 2nd of the same book describes the mode of working the mines of Sandaracurgium.

EPHESUS.

The entrance of the port of Ephesus is too narrow, the fault of the architects and engineers, who were led into error by the king, who employed them on this work. This prince, who was Attalus 2nd, Philadelphus, King of Pergamus, seeing that the port was being silted up with banks from the deposits of the Cayster, and thinking that it could be made deep enough to receive large vessels, if a mole were thrown before the entrance which was too broad, ordered the construction of the mole. The contrary however happened, for the sand filled the port with shoals as far as the entrance, whereas before the deposit was sufficiently carried out by inundations, and by the reciprocal movement of the waters of the outer sea. Such are the defects of the port of Ephesus (book 14, chap. 1).

PERSIA, &c.

Alexander in his expedition to Gedrosia was preceded by miners to search for water (book 15, chap. 1).

In book 15, chap. 3, a bridge is mentioned as being thrown over the Choaspes at Susa.

In the next page sluices are mentioned on the Tigris.

In book 16, chap. 1, an enumeration is made of the works of Semiramis.

Alexander destroyed a number of sluices on the river Tigris. He also occupied himself with the canals, which are of the greatest importance to the agriculture of that country (B. 16, ch. 1), a theme upon which our author dwells at some length. He relates, on the authority of Aristobulus (see also Arrian, B. 7, § 22), that Alexander, seated in a boat steered by himself, attentively surveyed the canals, and caused them to be cleaned by employing a great multitude of men, whom he took with him. He also had certain outlets closed and new ones opened. He remarked a canal, principally leading to the lakes and marshes on the Arabian side, and the outlet of which, on account of the softness of the ground, could not easily be closed; he therefore opened a new canal or mouth about 30 stades off, in a rocky ground, through which he turned the waters.

EGYPT.

In his 17th Book, Strabo describes Egypt. He mentions the skill the Egyptians showed in hydraulic works, but the fact upon which he dwells is partly perhaps attributable to Roman science. He says that before the time of C. Petronius (ch. 1) Governor, A. D. 20, that the greatest inundation and most abundant harvest took place when the Nile reached fourteen cubits, but that under the administration of that governor an inundation of twelve cubits produced abundance.

In that book and chapter there is frequent mention of canals, and there is a description of the canal of the Red Sea. (See also Diodorus Siculus, B. 1, § 19 and 33.

Here also Strabo describes the Egyptian mortar as being made of pounded basalt, brought from the mountains of Ethiopia.

PAUSANIAS—ÆLIAN AND APPIAN.

In Pausanias the only notices in any way relating to our subject are an allusion to the silver mines of Laurium in the commencement of the Attics, and in the Laconics a statement that Eurotas diverted the river. In Ælian and Appian there is nothing except perhaps that the latter, in the account of the siege of Carthage, mentions a cut made through the harbour by the Carthaginians.

ARRIAN.

Arrian in his Life of Alexander, 7th book, chap. 21st, gives a better account than Strabo of Alexander's repair of the canal called Pallacopas, although this latter account differs, we shall content ourselves with a reference to it. We may observe that Gronovius has annexed to his edition of Arrian a small treatise on this canal, which embodies all the account and modern information respecting it.

In his second book Arrian devotes much space to the siege of Tyre, from which we shall extract some of his remarks on the mole. He says that the sea there has a clay bottom, and shallow towards the shore; but when you draw near the city, it is almost three fathoms deep. As there was abundance of stone not far off, and a sufficient quantity of timber and rubbish to fill up the vacant spaces, they found no great difficulty in laying the foundations of their own rampart; the stiff clay at the bottom, by its own nature, serving instead of mortar, to bind the stones together. The Macedonians showed a wonderful forwardness and alacrity to the work, and Alexander's presence contributed not a little thereto; for he designed every thing himself, and saw every thing done. In describing the subsequent operations Arrian says that many engineers, meaning military engineers, were brought from Cyprus and Phenicia.

In the fifth book a long account is given of the mode adopted by the Romans, and particularly by the old Romans, in forming temporary bridges for crossing large rivers.

The British Queen Steam-ship.—This splendid steamer sailed yesterday for Antwerp. A select party of gentlemen went in her on a visit to Belgium. The British and American Steam Company have, it is said, received for her the sum of £60,000 from the Belgian government. For the President the same company received above £70,000 from the underwriters. The losses sustained by the company since its establishment are supposed not to be less than £60,000 nor more than £100,000.—*Liverpool Albion, Sep. 6.*

ON THE MANUFACTURE OF BRICKS AND TILES.

[We are indebted for the following article to a very useful work by Mr. Aikin, just published; we have appended some additional notes, which we think will be found useful, and make the article more complete.—Editor.]

Till lately, bricks appear to have been made in this country in a very rude manner. The clay was dug in the autumn, and exposed to the winter frosts to mellow; it was then mixed, or not, with coal ashes, and tempered by being trodden by horses or men, and was afterwards moulded, without it being considered necessary to take out the stones. The bricks were burnt in kilns or in clamps; the former was the original mode, the latter having been resorted to from motives of economy. When clamps began to be employed I do not know; but they are mentioned in an act of parliament passed in 1726, and therefore were in use prior to that date. The following, in few words, is the present process of brick-making in the vicinity of London, for the practical particulars of which I am indebted to Mr. Deville and Mr. Gibbs.

It is chiefly, I believe entirely, from the alluvial deposits above the London clay, that bricks are made in the vicinity of the metropolis and a section of these deposits generally presents the following series, such as would naturally result from a mixture of stones, and sand, and clay, and chalk, brought together by the force of water, and then allowed to subside. The lower part of the bed is gravel, mixed more or less with coarse sandy clay and pieces of chalk; this by degrees passes into what is technically called malm, which is a mixture of sand, comminuted chalk, and clay; and this graduates into the upper earth or strong clay, in which the clay is the prevailing or characterizing ingredient, the proportion of chalk being so small that the earth makes no sensible effervescence with acids. Bricks made of the upper earth, without any addition, are apt to crack in drying, and in burning they are very liable to warp, as well as to contract considerably in all their dimensions; on this account they cannot be used for the exterior of walls; and a greater number of such are required for any given quantity of work than of bricks, which, though made in the same mould, shrink less in the baking. The texture, however, of such bricks is compact, which makes them strong and durable. Bricks formed of this clay, whether mixed or unmixed, are called stocks; it was formerly used unwashed, and when the bricks were intended to be kiln-burnt, or *flame-burnt*, to use the technical word, no addition was made to the clay. If they were intended to be clamp burnt, coal-ash was mixed during the tempering. Of these and all other clamp-burnt bricks the builders distinguish two kinds, namely the well-burnt ones from the interior, and the half-burnt ones, or place bricks, from the outside of the kiln.

The calcareous clay or malm earth requires no addition of sand or chalk, but only of ashes. The bricks made of it differ from those made of the top earth, in being of a pale or liver brown colour, mixed more or less with yellow, which is an indication of magnesia. The hardest of the malm bricks are of a pale brown colour, and are known by the name of gray stocks; those next in hardness are called seconds and are employed for fronts of the better kind of houses; the yellowest and softest are called cutters, from the facility with which they can be cut or rubbed down, and are used chiefly for turning the arches of windows. What I have said of top earth and malm earth must be understood, however, to refer to well-characterized samples of these varieties, but, as might be expected, there are several brick-fields that yield a material partaking more or less of the qualities of both and therefore requiring corresponding modifications in its manufacture.

Brick earth is usually begun to be dug in September, and is heaped rough, to the height of from four to six feet, on a surface prepared to receive it, that it may have the benefit of the frost in mellowing it and breaking it down. It is then washed by grinding it in water and passing it through a grating, the bars of which are close enough to separate even small stones. The mud runs into shallow pits, and is here mixed with chalk ground with water to the consistence of cream if any calcareous ingredient is required. When it has become tolerably stiff by drying, coal ashes (separated by sifting from the cinders and small pieces of coal) are added, in the proportion of from one to two and a half inches in depth of this latter to three feet of clay, the most tenacious clay requiring the greatest quantity of ashes. The ingredients are then to be well mixed; and, finally, the composition is to be passed through the pug-mill,* in order to complete the mixture

---

* The pug-mill is an iron cylinder set upright, in the axis of which an arbor or shaft revolves, having several knives, with their edges somewhat depressed, projecting from it and arranged in a spiral manner round the arbor. By the revolution of the arbor the clay is brought within the action

and to temper it. The moulder stands at a table, and the tempered clay is brought to him in lumps of about 7 or 8 lb.; the mould is a box without top or bottom, $9\frac{1}{2}$ inches long, $4\frac{1}{2}$ wide, and $2\frac{3}{4}$ deep;† it lies on a table; a little sand is first sprinkled in, and then the lump of clay is forcibly dashed into the mould, the workman at the same time rapidly working it by his fingers, so as to make it completely close up to the corners; next he scrapes off with a wetted stick (*strike*) the superfluous clay, throws sand on the top, and shakes the brick dexterously out of the mould on to a flat piece of board, (*a pallet board*) on which it is carried to a place called the hacks formed of the new bricks, into open hollow walls, which (in wet weather) are covered with straw to keep off the rain; here they dry gradually, and harden till they are fit to be burnt. A raw brick weighs between 6 and 7 lb.; when ready for the clamp it has lost about 1 lb. of water by evaporation.* A first-rate moulder has been known to deliver from 10,000 to 11,000 bricks in the course of a long summer's day, but the average produce is not much more than half this number (1).

The price of bricks varies from forty to sixty shillings a thousand, of which not more than one shilling and three pence a thousand, at the utmost, can be the cost of moulding, assuming the average work of a moulder to be five thousand in a day; any improvement, therefore, calculated to save time in this department of brick-making by the introduction of machinery worked by steam, or by horse power, can only amount to a benefit equal to a fraction of one thirty-second or one forty-eighth of the entire price of the commodity. If we assume such machine to produce fifty-two million bricks in a year, this amounts to two millions a week (for the season for brick-making in this country continues no longer than from April to September inclusive) or three hundred and thirty thousand in a day, equal to the labour of sixty-six men or eleven horses, without making any allowance for friction, or any deduction on account of temporary repairs. The cost of hand-moulding fifty-two million bricks at one shilling and three pence per thousand is 3250*l.* from which, if we deduct the first cost and repair of machinery, the expense of fuel or of horses, of superintendence, &c. it would probably be found that nothing would remain for profit.

Bricks are burnt either in kilns or in clamps (2). In the former the burning is completed in twenty-four hours; in the latter it requires from twenty to thirty days, but is on the whole cheaper, notwithstanding that the loss from over-burning, from under-burning and other accidents amounts to one-tenth of the whole number of bricks (3).

The consumption of London is for the most part supplied from the brick-fields that surround it in all directions, the principal of which, however, are situated north of the Thames, at Stepney, Hackney, Tottenham, Enfield, Islington, Kingsland, Hammersmith, Cowley, Acton, and Brentford. Those made at Grays Thurrock, Purfleet, and

---

the knives, by which it is cut and kneaded, and finally is forced through a hole in the bottom of the cylinder.

* A malm brick of the above dimensions will shrink by burning to the length of 9 or $9\frac{1}{4}$ inches. A brick made of top clay without any mixture of chalk, will often shrink to $8\frac{1}{2}$ inches.

† From some experiments made in France we learn the following particulars:—A mould 8 inches 3 lines long, 4 inches, 3 lines broad, and 2 inches 2 lines thick, yielded bricks which on an average weighed, when first made, 5 lb. 14 oz. When dried and ready for the kiln they weighed 4 lb. 8 oz. having 22 oz. of water; 9 oz of this quantity evaporates in the first twenty-four hours, the other 13 oz. require five or six weeks to evaporate. By burning, 4 oz. more of volatile matter is driven off; a well-burnt brick of the above dimensions weighing 4 lb. 4 oz. A fresh-burnt brick when laid in water absorbs about 9 oz. *i. e.* from one-seventh to one-eighth of its weight.

It appears, however, from experiments by M. Gallon, that the weight of bricks varies according to the care with which the clay is worked or tempered. Some clay was well worked, and then beaten for half an hour, on the morning of the next day it was again worked and beaten as before, and in the afternoon was again beaten for a quarter of an hour, and was then made into bricks. Another parcel of bricks was made of some of the same clay, treated in the usual manner. Both parcels were dried in the air for thirteen days, when it was found that those made by the former process weighed on an average 5 lb. 11 oz. each, while those made by the latter weighed 5 lb. 7 oz. Both kinds were burnt together for ten days; they underwent no relative change in bulk, but the weight of the former was 5 lb. 6 oz. and of the latter 5 lb. 2 oz.—*Arts et Metiers*, vol. iv.

(1) The operation of making the bricks is generally undertaken by one man called the moulder, who with his wife, children, and one or two men, form a gang. One of the gang, a man, wheels the soil to the pug-mill; after it is tempered it is removed by a boy or girl from the pug-mill to the *banker*, (the moulder's work-bench), it is then kneaded by a woman, who passes it to the moulder next to her, and as fast as the moulder turns the bricks out of the mould, they are removed by a boy on to the off-bearing barrow, which is wheeled to the drying-ground by 1 or 2 men, who set up the bricks in the hacks in a slanting direction, two in width, and about two inches apart, and 3 feet high; these hacks run the whole length of the drying ground and are placed in parallel lines 4 to 5 ft. apart. When the bricks have stood a few days, they are reset with a greater space between them, which operation is called *scintling*, and in about a week after, they are removed to the clamp or kiln.—Ed. C. E. & A. Journ.

(2) A clamp is formed first by raising the earth a few inches above the natural surface of the ground to an uniform level; some of the hardest of the new made bricks, or, if there be any in the field, some old bricks previously burnt are set on edge over the whole site of the intended clamp, which are to prevent the moisture of the ground penetrating the new made bricks. Flues are then formed by the bricks being laid side by side, with a small space between to the height of 3 feet and about 9 inches wide; the top is covered by bricks being set off on each side, until they form an arch or covering; these flues run the whole length of the clamp, and generally about 6 feet apart; they are filled with furze or dry faggot wood, over which are laid small sea coal, or breeze (cinders), the intermediate spaces are filled in with bricks (this operation is termed *crowding*) laid a short distance apart, and between each course a layer of breeze is laid and repeated the whole height. The upper courses are laid a little closer than the lower ones, as they receive a greater proportion of heat, the outside of the clamp is generally closed in with place bricks (half burnt or soft bricks), and the top covered with breeze and sometimes earth; when the clamp is made up the fuel in the flues is ignited, which communicates with the breeze laid between each course, and shortly the whole of the clamp is in a state of combustion, and becomes one mass of fire, communicating with the ashes contained in the bricks; part of the exterior is sometimes coated with clay to prevent the cold winds penetrating. As soon as the whole of the clamp is properly ignited, the flues are closed, when particular attention is required to prevent the fuel burning too fiercely or too slowly. If it burn or draw too quickly on either side, screens are placed on the outside to check the draught. When the whole is properly burnt, which is in about 25 or 30 days, the clamp is partially opened and allowed to cool; the bricks are then sorted, those which are properly burned are called *stocks*—if they are not sufficiently burned they are of a pale red colour and soft, called *place bricks*—if the fire has acted too fiercely, several of the bricks will be vitrified into one solid mass, which are called *burs*. The whole operation of making bricks from the time the earth is turned into the pug-mill to the time the clamp is open, averages about 6 weeks.

The kiln is of an oblong form, brick built, with one opening in the end or side, and generally 13 feet long, 10 ft. 6 in. wide, and 12 feet high; and will contain about 20,000 bricks, the walls, on the top, are about two bricks thick, and at the bottom three bricks; they are built battering (inclining) inwards, the bottom is covered with narrow recesses arched over with openings left in the top, having the appearance of lattice work, in these recesses is deposited the fuel, on the top the bricks are laid with spaces between to allow the fire to pass up; the upper courses are laid a little closer than the lower ones, and the surface covered over with old brick or tile rubbish to keep in the heat and prevent the rain damaging the upper bricks; when the kiln is full, some wood is put in and ignited, to dry them thoroughly; when this is done, which is known by the smoke becoming transparent, the mouth of the kiln is closed with old bricks and covered with clay, leaving sufficient space for faggot; brushwood, furze, bavins or dry faggot wood to be put in and lighted. The fire being made up it is continued till the ashes assume a whitish appearance, and the flames appear through the top of the kiln, the fire is then slackened and the kiln cools by degrees. The process is continued, alternately heating and slackening till the bricks are thoroughly burned, which is generally in the space of 48 hours. The advantages of kiln burning is the greater certainty in the operation and shortness of time in burning, which is done in about two days, whilst the operation of clamp burning occupies frequently 30 days. The bricks are generally of a bright and sometimes dark red colour.—Editor C. E. and A. Journal.

(3.) The following are the prices for the several operations in brick making:—

DIGGING PER CUBIC YARD.	s.	d.
To digging the uncallow, including wheeling not exceeding *one run* (a run is three 20 feet planks placed in a continuous line, lengthways)	0	4
Digging and wheeling brick earth	0	4
Turning and soiling (mixing sand or ashes with the brick earth	0	$2\frac{1}{2}$

MAKING, PER THOUSAND.	s.	d.
Making the bricks, including the tempering of the clay, molding, and hacking (stacking)	4	0
Scintling (removing and restacking the bricks in the hacks)	0	$2\frac{1}{2}$
Crowding (placing) the bricks in the clamps or kiln	1	$4\frac{1}{2}$
Two yards of clay or brick earth (which will make one thousand bricks) digging and soiling at $6\frac{1}{2}$*d.* per yard	1	1
Wear and tear of tools (found by the master) and keep of horse	2	0
One-fifth of a chaldron of ashes for soiling, at 5*s.* per chaldron	1	0
One-fifth ditto of breeze for fuel, 7*s.* 6*d.* ditto	1	6
Straw 6*d.*, sand 6*d.*	1	0
Kiln or clamp expenses for attending to open it, loading carts, &c.	1	0
Duty	5	10
Rent	2	0
	£1 1	0

To the above must be added the expenses for removing the uncallow, risk losses, interest on capital sunk, &c. and if washed the additional labour and cost of chalk, &c. Stock bricks average at this time about 30*s.* to 32*s.* per thousand, in the field, and place bricks 24*s.* The price for the latter is almost prime cost, consequently a greater profit must be allowed on the stocks to cover all losses, which in wet seasons are very serious. The duty is obliged to be paid on the quantity in the hack, notwithstanding any part or the whole may be damaged or destroyed by wet weather or in process of manufacture; for these risks government allow 10 per cent., reducing the duty to 5*s.* 3*d.* per thousand on the quantity made before burning.—Ed. C. E. & A. Journ.

Sittingbourne, are of a very good quality and a fine yellow colour; stone-coloured ones are made near Ipswich, and have been largely employed in the outside walls of some of the new churches of the metropolis. At Cheshunt, in Hertfordshire, is a bed of maim earth of the finest quality, no less than twenty-five feet in depth; from this are made the best small kiln-burnt bricks, called paviors. They are hard, absorb very little water, and are used for paving the floors of stables, wash-houses, &c. They have entirely superseded the use of Dutch clinkers, which formerly were imported from Holland in large quantities. The red sandy bricks called Windsors are made at Hedgerley. There is a considerable exportation of bricks from London; many being sent to the West Indies, to Quebec, and to other colonies.*

Tiles, from the purpose to which they are applied, namely, roofing houses in order to shoot off the rain, require a texture as compact as can be given to them, consistent with a due regard to economy. The fattest and most unctuous clays are, therefore, those which answer the best, especially if free from gravel and the coarsest sand. The price of tiles, compared with that of bricks, is such that the manufacturer can afford to dry them under cover; while, being not more than one quarter of the thickness of bricks, the drying is more speedily performed, and with far less hazard of warping or cracking: the same also is the case with the baking. Sand is added to the clay, but sparingly; for if, on the one hand, it prevents the ware from warping, yet, on the other hand, it increases the porosity, which is a fault especially to be avoided. The general manipulations of grinding the clay and tempering it are analogous to those already described for making bricks; but more pains are bestowed in getting it to the utmost degree of plasticity so as to allow of its being rolled, like dough, into cakes of a proper thickness, which are afterwards brought to the required shape by pressing them into a mould.

ON THE PERCUSSIVE ACTION OF STEAM.

Our correspondent C. S. in the last number of the Journal has taken an observation which we made in the first part of our article on this subject in the August number in a wrong light; nor should we have expected him to have attached so much importance to that observation after reading the rest of the article, from which he would have seen that, if we thought it unfair of Mr. Parkes to attribute all the advantage of percussive action to Cornish engines, and none to others, we also considered the amount of that advantage to be *equal to nothing*, which we think clearly demonstrated by our reasoning; so that we cannot exactly be of opinion that Mr. Parkes *favours* the Cornish engines, simply by considering that the percussive force of steam is only developed in them. The remark that this force should be developed in a greater degree in Locomotive engines does not necessarily imply that it should be developed favourably; for, by reason of the lead given to the slide valve in those engines, the steam is first let on to the back of the piston, and its percussive force would therefore tend, as our correspondent justly observes, "to impede the engine, if not stop it altogether."

The rest of our correspondent's remarks, since they have for object "to show that the Cornish single-acting engines are the only ones at present in which the percussive force of steam could act with any very great advantage, and that the locomotives are the very worst in which it could be used as a motive force," and thus suppose the fact of its advantageous action in the former to be already established beyond all question, cannot be regarded as an answer to our article above mentioned, but merely to the single remark already alluded to, and to which he has, as we have shown, attributed a meaning we never intended it to convey. It is difficult to assign a reason for his replying to the least important portion of our article, and passing over the main argument in silence.—Is it that he considers the question of the propriety of applying the principle of Percussion to the action of the steam as above discussion?—This was not very reasonable, since he has, so far as we are informed, the authority of but one writer, the infallibility of whose theories has not hitherto been established by experience; in proof of which, see the Count de Pambour's paper *On Momentum proposed by Mr. Josiah Parkes as a Measure of the Mechanical Effect of Locomotive engines*, and our Reviews of Mr. Parkes' paper on the same subject, in the Journal of last year, page 102. We must, however, assume this to have been our correspondent's motive for abstaining from any discussion of the principle of the percussive action of steam, as otherwise we should be reduced to the alternative of either supposing that he did not understand the [illegible] we demonstrated, or attempted to demonstrate, [illegible] followed Paddy's plan of beginning at the end. Be this as it may, the following remarks may perhaps induce C. S. to modify his opinions in some measure.

He observes that, "in a common double-acting rotative engine, where the steam is let into the cylinder when the crank is just passing the centre, it is evident that any percussive force of the steam striking upon the piston could not by any means have any effect in turning the crank." But he states further on that "the action of this force is avoided in this case, as well as in that of the Locomotive engine, by the gradual motion of the slide, for as soon as the slide begins to open the steam way, the steam rushes into the cylinder, and strikes upon the piston, but with very little effect, on account of its being so much wire-drawn in consequence of the small size of the opening at first." It would naturally be inferred from this latter observation that our correspondent supposed the percussive action of the steam to be confined to the moment when the valve begins to open, in other words, that it is only *the first portion* of the steam which has any percussive action, and that this action is communicated instantaneously to the piston the moment that portion of steam passes through the valve; which, if it were true, would obviate the development of percussive action in Cornish single-acting engines as well as in those above mentioned; for the steam valve of a Cornish engine, though opened more suddenly than the slide valve, is nevertheless not opened instantaneously, but more or less gradually. If, on the other hand, we assume the development of this action to occupy some time, however brief, so as to allow of the opening of the valve of the Cornish engine, (which is equally necessary for the double-acting rotative engine), then must we also admit, not only that there is percussive action in the latter as well as in the former, but also that this action must assist in turning the crank, which will have passed the centre before it has ceased to operate.

We do not agree with C. S. in the opinion that "in order to render the percussive force of steam available to its fullest extent as a moving power in single-acting pumping engines, it would be necessary to have some medium interposed between the direct action of the steam on the piston and the pumps; so as to convert the ever-varying pressure on the piston into a regular and steady pressure on the plunger of the pump;" for the condition of a constant pressure on the pump bucket, is by no means indispensable, as the effect of a diminution of pressure on the steam piston, supposing such medium not to exist, would be simply a corresponding diminution of the velocity, or of the acceleration of the bucket and column of water, which would by no means affect the application of the percussive force of the steam. This column of water is, however, considered by C. S. as a medium interposed between the direct action of the steam on the piston and the pumps, which is curious enough, since the action of the steam works the pumps, and these raise the column of water.

We cannot make out that our correspondent's remarks have in any degree shown, as he supposes, "that in the Cornish engine we might use the percussive force of steam as a moving force to a very considerable extent;" for such negative evidence as that which he reproduces from Mr. Parkes' paper, viz. that the duty performed by those engines is greater than he could otherwise account for, cannot be admitted as rigorous. What is required of the supporters of Mr. Parkes' opinions is a *direct* proof that in Cornish or any other engines, the steam develops a power, by means of percussion, *in addition to* that measured by its elastic force, without which it is idle to enter into any discussion respecting the comparative fitness of different kinds of engine for the development of this additional power.

ON THE POWER OF THE SCREW.

We have received a letter from Mr. J. R. Cassen, in defence of the views set forth by him in a communication published in our Journal for May last, and which were partially refuted by a correspondent in the July number. We cannot insert this letter, since it is evident that the writer is in error on all points; but for his information, and the information of any other persons who may be led into error by his arguments, we shall point out clearly in what his mistakes consist, and how they have probably arisen.

As to his first objection to the theory laid down by the Rev. Mr. Bridges, our July correspondent alluded to above is undoubtedly right with regard to the meaning of d, which signifies the height of the inclined plane, or distance between the top of one coil of the thread of the screw and the top of the next, which is the distance through which the resistance is moved in one revolution of the screw,

* The whole number of bricks made in Great Britain and Ireland in the year 1835, on which the excise duty was paid, was 1960 millions.

which is called the pitch of the screw, it could not possibly signify, as contended by Mr. Cussen, the distance from the upper side of one coil of the thread to the upper side of the next, as that would admit of an infinite number of different solutions to the problem of finding the power necessary to overcome a given resistance, according as the ratio of the thickness of the thread to the interval between its coils might be more or less, which circumstance could not effect the result, since it is only the upper side of the thread, or that which is in contact with the resistance, which sustains the resistance. Mr. Cussen may, therefore, rest satisfied that all theorists agree with him in substance, if not in expressions.

Respecting his second objection, Mr. Cussen has overlooked the chief part of the theory of the *lever*, and, unless he objects to that theory also as now taught by *all* authors and professors without exception, the following reasoning will convice him of his error.

We will take his examples of the three screws, each of ½ inch thread, which, converted into intelligible mechanical language, is one inch pitch, and of 3, 6, and 9 inches diameter respectively, worked by a lever of 90 inches long, the lever moved by a windlass of one ton power. But it is necessary first to understand clearly what is meant by a lever 90 inches long. In mechanical language its signification is the distance in a straight line from the fulcrum (which is in the axis of the screw) to the point of application of the power, which does not, however, seem to be the meaning attached to the expression in Mr. Cussen's second letter; he seems rather to mean the distance from the *surface of the cylinder* to the point of application of the power, which is not the true measure of the power of the lever; we shall therefore take the liberty of understanding it in the former sense. This being premised, suppose for a moment that no lever is used; we shall have, by Mr. Cussen's, as well as by Mr. Bridges' formula:

in the first case $1 : 3 \times 3{\cdot}1416 : : 1 : w = 9{\cdot}4248$ tons,
in the second case $1 : 6 \times 3{\cdot}1416 : : 1 : w = 18{\cdot}8496$ tons,
in the third case $1 : 9 \times 3{\cdot}1416 : : 1 : w = 28{\cdot}2744$ tons.

Now the power is applied in the first case at a distance of 1½ inch from the fulcrum, in the second at 3 inches, and in the third at 4½ in. distance; so that, by applying it at a distance of 90 inches in all three cases, we shall obtain the following results respectively:

in the first case $1\frac{1}{2} : 90 : : 9{\cdot}4248 : w = 565{\cdot}488$ tons,
in the second case $3 : 90 : : 18{\cdot}8496 : w = 565{\cdot}488$ tons,
in the third case $4\frac{1}{2} : 90 : : 28{\cdot}2744 : w = 565{\cdot}488$ tons,

or the pressure independent of the diameter of the screw, which overthrows the second objection.

Mr. Cussen's third objection falls to the ground with the preceding, indeed it has no meaning at all; for he *virtually* multiplies by the circumference of the circle described by the extremity of the lever when he multiplies by the circumference of the screw and by the length of the lever, although he omits to divide by the semidiameter of the screw, as he ought in that case to do, and as it will be seen, on an inspection of the above calculations, we have done to obtain the final value of w. If we take the first case, we had finally

$$w = \frac{1 \times 3 \times 3{\cdot}1416 \times 90}{1 \times 1\frac{1}{2}},$$

and it is obviously the same thing whether we suppose 3·1416 to be first multiplied by 3, to give the circumference of the screw, and the product to be afterwards multiplied by 90 the length of the lever, and divided by 1½ the semidiameter of the screw, as above, or whether we suppose 3·1416 to be first multiplied by *twice* 90, to give the circumference described by the extremity of the lever, and as the factor 3 of the numerator is essentially twice the factor 1½ of the denominator, these two factors disappear. Or, to make it still more apparent, let r represent the radius of the screw, d its pitch, l the length of the lever (measured from the axis of the screw), P the power and w the resistance. Then the last equation would be

$$w = \frac{P \times 2\,r \times 3{\cdot}1416 \times l}{d \times r}$$

from which it is evident that, if we take the 2 from the factor $2\,r$, and multiply it by the two factors 3·1416 and l, we shall obtain the circumference described by the extremity of the lever, or by the power; and this product, multiplied by $P \times r$ will obviously be the same as if the product $2\,r \times 3{\cdot}1416$, which is the circumference of the screw, were multiplied by $P \times l$. But Mr. Cussen has committed the error of leaving out the factor r in the denominator, forgetting that when no lever is used, the power is applied at the circumference of the screw, and that the leverage is equal to r, so that when the leverage is increased to l, the resistance is increased in the ratio $\frac{l}{r}$. Having demonstrated Mr. Cussen's error, and shewn its probable origin, we may now cancel the r in the numerator and denominator of the fraction, and it will remain

$$w = \frac{P \times 2\pi l}{d},$$

π being the ratio of the circumference of a circle to its diameter.

If Mr. Cussen's remark "that one-third of the calculated power is lost by friction," is meant to bear upon the comparison of the effect of screws of different diameters but the same pitch, it will be found on investigation that the friction bears no fixed ratio to the resistance, but increases in a slightly greater ratio than the diameter of the screw, and thus gives a proportionate advantage to screws of small diameter.

ON THE ECONOMY OF FUEL IN LOCOMOTIVES CONSEQUENT TO EXPANSION AS PRODUCED BY THE COVER OF THE SLIDE VALVE.

Sir—Having observed several errors in Mr. J. G. Lawrie's calculations, published in your useful and interesting Journal for August last, allow me to point them out for the benefit of your readers.

I should premise that the formulæ he has given for the several distances travelled by the piston: from the commencement of the stroke to the commencement of expansion, from the commencement of the stroke to the opening of the eduction port (not to the end of expansion, for expansion continues, but more rapidly, and the effect during the rest of the stroke is not to be neglected), and from the commencement of the stroke to the position of the piston when the valve opens for the lead of the next stroke, are correct. I should however observe that the expressions under the radical sign in the values of a' and c' are identical, and may be reduced to $(1-c^2)\,[1-(l+c)^2]$; and perhaps it would be better if the expressions $(1-l\,c-c^2)$ and $(1+l\,c+c^2)$ in the same two values were written respectively

$$[1-c\,(l+c)\,] \text{ and } [1+c\,(l+c)\,].$$

The errors I have discovered are in the computation of the effect, which follow.

Mr. Lawrie finds the volume of steam of the initial pressure p admitted during the stroke to be equal to $s\left(a' - \frac{(2\,d-b)\,t}{p}\right)$, (at least I suppose this expression to have been meant by the writer, although the factor s is omitted and h is printed instead of p in the denominator,) which is a sufficiently near approximation, but I cannot comprehend how he can make this quantity equal to $2\,d \times 1$, although he observes with truth that the quantity of fresh steam must (whatever the expansion is) be constant; but a constant quantity is not necessarily an arbitrary one, as which it might be considered in this case, for we may give s any value we please, and it would follow that the quantity of steam used per stroke would be the same, whatever the area of the piston might be, provided the length of stroke, lead and cover of the slide were the same. And if we supposed the area of the piston $s = 1$ square foot (a reasonable hypothesis), the factor 1 in the expression $2\,d \times 1$ signifying (as I suppose) also 1 square foot, we should necessarily have $a' - \frac{(2\,d-b)\,t}{p} = 2\,d$, which is impossible for $a' \angle 2\,d$. His expression of the value of s is therefore incorrect; besides it is obviously impossible to deduce the area of the piston from the length of stroke, cover and lead of the slide, and ratio of the greatest to the least pressure in the cylinder, without knowing how much steam is generated in the boiler.

Secondly, the effective working pressure during the expansion is found $= \frac{a'p}{x} - t$, x expressing the distance travelled by the piston from the beginning of the stroke; and this expression will give too great a value by 3 or 4 lb. per square inch, if not more; for t is used to express the least pressure of the steam in the cylinder, which it has at the moment when the eduction port is closed, and which probably scarcely exceeds the atmospheric pressure, and the mean resistance of the waste steam amounts to 4 or 5 lb. per square inch. Besides this, the formula given to express the quantity of work done during the portion b of the stroke makes no allowance for the diminution of temperature consequent on expansion; but this may be too slight to be of any consequence, as the expansion is inconsiderable in locomotives; nor is any allowance made for the waste space which has to be filled with steam. But the effect during the rest of the stroke is not to be neglected, that is, from the moment when the eduction port is opened to the termination of the stroke; for, on account of the very small opening of the port during that period, very little steam is enabled to escape, and it had previously been but slightly reduced in pressure by expansion, so that its mean pressure during this last portion of the stroke will bear a considerable proportion to its initial pressure, and cannot therefore be neglected. On the other hand, the effect of the compression of the spent steam of the pressure t, between the instant of shutting the eduction valve and that of opening the steam valve, is so small that it might much rather be disregarded; for it commences with a pressure of about 1 atmosphere and terminates with about 1·4, say on an average ½ atmosphere through one-fortieth part of the stroke, or about one-tenth of a lb. through the stroke, due to compression.

Thirdly, Mr. Lawrie makes the inexplicable assumption that the safety valve be so loaded that $p = s$ — the initial pressure of the steam in atmospheres = the area of the piston!—Supposing the square foot to be the unit of area, and $s = 1$ square foot; we should then have $p = 1$ atmosphere, and the engine would not move; but if the square inch were the unit of area, for the piston of the same size as before we should have $s = 144$ square inches, and consequently $p = 144$ atmospheres!—These results show the manifest absurdity of the supposition.

Lastly, the values of a', b and c', in the examples which close the paper, are not determined correctly from the formulæ which, I said above, are themselves correct, so that the whole paper requires revision and correction, except the first part, as I have explained.

Hoping that the above remarks may be found serviceable to your readers,

I remain, &c.,

M.

MR. JOSIAH PARKES IN REPLY TO COUNT DE PAMBOUR.

Mr. Editor—M. de Pambour has recently repeated, in several of the weekly and other periodicals, certain virulent strictures on my writings. I am at a loss to conjecture on what grounds that individual should have indulged in these, as well as in his earlier, and nearly similar, attacks upon me. I have, hitherto, declined replying to them, and for two reasons; first, I did not wish to convict a man of M. de Pambour's celebrity of deliberate misrepresentation; nor, secondly, to expose, more publicly than he had himself done to persons really conversant with the steam engine, his lamentable ignorance of practical matters. But, his resumption of these attacks, in the present form, renders it incumbent on me to be no longer silent. I, therefore, avail myself of the same medium of communication, and shall confine my reply to the exhibition of one instance of his gross ignorance, and of one instance of his numerous, and injurious, falsifications of my opinions and writings.

Every engineer is acquainted with the *cataract*, an instrument nearly as old as Newcomen's engine, and used for the purpose of opening the steam induction valve, and thus starting an engine, after any required period of rest. This species of water clock is also occasionally employed to open other of the valves at definite times. The Cornish engineers appreciate its value, not only as a means of regulating the number of strokes to be made by a pumping engine, in a given time, but also as effecting the influx of steam into the cylinder in the most instantaneous manner. Neither they, nor any other engineer ever, probably, imagined the cataract to exercise an influence over the *production of steam* in the boilers of their engines. The Comte de Pambour, however, ascribes to the instrument this miraculous virtue, in the following passage:

"We will finally remark that it is customary in these engines to make use of the *cataract*. Under this circumstance the engine does not evaporate the full quantity of water, that its boiler would otherwise be capable of evaporating per minute; but, on introducing into the formula the evaporation really effected, the formulæ will always give the corresponding effects of the engine."—(*New Theory of the Steam Engine. J. Weale*, 1839, *chap.* xi., *Cornish Single Pumping Engine, p.* 278.)

This *is*, verily a *new theory*. No observations of mine are requisite to illustrate the absurdity of theories, and formulæ, emanating from a person who is so little practically versed in the mechanism, and auxiliary apparatus of an engine, as to jumble together, and confound, in one paragraph, the distinct functions of the *cataract*, the *boiler*, and the *engine*.

In a later work, M. de Pambour has devoted no less than 16 pages of introductory matter to a criticism of my Paper on the Locomotive Engine, (published in the Transactions of the Institution of Civil Engineers, vol. iii.), in which, among others, I had occasion to examine his own experiments. In that paper, not a word will be found disrespectful of M. de Pambour; his sentiments are treated with courtesy; and, at the risk of being thought tedious, I prefaced each of my observations on his conclusions with a quotation of the matter commented upon. M. de Pambour's reply contains numerous misapprehensions of my meaning, and arguments, of which I do not complain; but every author has fair ground of complaint against the antagonist who perverts his text; who invents arguments for him; or who cites, as authentic quotations, phrases which he never employed. In no one instance has M. de Pambour quoted my own words; in lieu of which he has frequently invented words and opinions for me. The following extract affords a concise example of the veracity and style of the 16 pages of criticism.

"The want of using equations which facilitate so much accuracy in mathematical reasoning (*and the author accounts for it in telling us that he is more accustomed to handle his hammer than his pen,*) causes him to heap errors on errors, combining and complicating them unaware, till he arrives at a point where he does not produce a single result that is not erroneous."—(*A Practical Treatise on Locomotive Engines*, 2nd edition. J. Weale, 1840. *Introduction*, page xxxiii.)

The paragraph in italics is a pure invention. No such words even occur in my paper as *hammer* or *pen*.

The writer who resorts to the miserable tactics of falsifying the language and opinions of one who differs from him on subjects open to large controversy, exhibits a consciousness of inferiority in his arguments, which it would have been wiser, and far more manly to acknowledge, than to attempt to conceal, by expedients so unworthy and so certain of detection. Such a man may, possibly, be a skilful mathematician, but he cannot claim rank among *philosophers*, whose sole objects are the discovery and propagation of *truth*. I consider myself exonerated from all obligation to reply, in greater detail, to an adversary who descends to such ignoble practices; but justice to my own reputation requires that I should expose them to public reprobation. This I do with the more regret as I have derived both instruction and pleasure from some parts of M. de Pambour's researches.

I remain, Sir, your obedient servant,

Josiah Parkes.

12, *Great College-street, Westminster, September* 13, 1841.

LONG AND SHORT CONNECTING RODS.

Sir—In your September number there are two communications animadverting on my paper on connecting rods in the July number. In this paper, my object was to establish the soundness of the connecting rod, *in general*, as a medium of moving force, and thereby to endeavour the settling of the controversy about long and short rods. For it is not disputed by any, I presume, that the strains and consequent friction between moving parts, in machinery, occasioned by connecting rods on the same crank, are in a certain proportion to their lengths and I agree that herein longer rods have the advantage of shorter. But the question has been, whether, purely as transmitters of force the former has any superiority to the latter, which leads to the question whether generally and abstractly, connecting rod motion is just as a medium of force. As I have said, it was my object to prove the affirmative of the question. Therefore, in this view of the subject rods of different lengths to the same crank ought to be one in effect.

Though certainly I did not notice the fact, I was aware that the connecting rod would not work on a crank of the same length in the usual style. We may mention, however, that a modification of this case is in fact practised in epicycloidal motion, a demonstration of which is given in March number for last year, in which the stroke of the piston is twice the throw of the crank, and the radius of the inner wheel is the connecting rod.

I am, Sir, your's, obediently,

D. Clark.

Glasgow, September 16, 1841.

Artesian Well at Grenelle.—M. Mulot, in some of his recent experiments at the Artesian well in the abattoir of Grenelle, succeeded in forcing the jet of water as high as 63 feet above the ground, and when it reached this height the water assumed a bell shape, ten metres in diameter, which produced the most picturesque effect. Unfortunately the water continues muddy; therefore, though there is a certainty of being able to procure nearly 2000 litres of water in the course of a minute, at a height which admits of its being conveyed into the highest stories of the houses in Paris, it is not yet known to what purposes the water can possibly be applied.

EPISODES OF PLAN.

(Continued from page 290.)

The breaks and interruptions occasioned by our "Episodes" being given to the reader piecemeal in monthly portions, are attended with no injury to our essay, and with some convenience to ourselves, by in some measure concealing abruptness of transition from one subject to another, and by enabling us to avail ourselves of such pauses, in order to bring such incidental remarks as we may deem expedient. Such being the case, we venture again to remind our readers that the plans here presented to them, are intended merely to furnish ideas in respect to form and arrangement; for, as we ourselves are perfectly aware, they would require to be more or less modified, in order to adapt them according to the other—and to us, of course, unknown—circumstances attending any given case. For more frequently than not, probably, it would be considered necessary to retrench and simplify them, to consult effect less and economy more. Accordingly there is very little danger of their being borrowed from in so direct a manner, that application of them would be tantamount to plagiarism, more especially, as hardly any two persons would produce the same design from the same plan.

Should any one be of opinion that those here produced might be greatly improved upon as regards further development of the ideas contained in them, great would be our satisfaction at finding any of them so turned to account, or otherwise corrected and matured. It is possible, however, that a very different construction may be put upon our motives, and that it will be thought to betray somewhat too much of self-complacency, if not of arrogance, on our part, to suppose that our suggestions can be of any value to other persons. Such presumption, if presumption it be, we, of course, partake in common with all who publish designs of their own; but with this difference, that while they give entire plans of houses, as if they were so many perfect models in every respect, we merely throw out partial hints, without presuming to dictate any further. In so doing, we of course leave it to be inferred that we think sufficiently well of our ideas as to imagine they may possibly prove serviceable to others, and of the two, it is surely less offensive to suppose that architects can have occasion for any promptings of such kind, than that they can at all require studies for the arrangement of ordinary houses, or can obtain fresh instruction from plans which are, for the greater part, of the most familiar and every-day character.

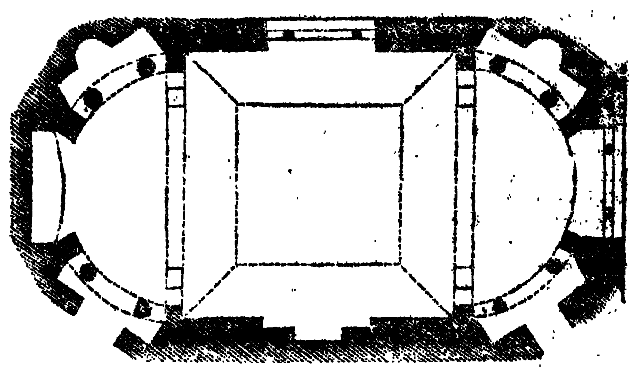
On the other hand, it may fairly be urged against ourselves and our Episodes, that the latter manifest too much straining after novelty and architectural display; that no regard is paid in them to economy, and that, in fact, they are applicable to general purposes, nor at all likely to suit the taste of persons in general. This is too true for us to attempt to contradict it; we leave persons in general, be they architects or those who employ them, to adhere to the present jog-trot system, taking no thought or study in regard to effects arising out of plan and varied combinations, but satisfying themselves that every thing in regard to plan is accomplished, provided that the number of rooms of the dimensions required be obtained, and mere convenience sufficiently attended to, which last, however, is far from being invariably the case, where the plan is only divided into so many squares and parallelograms.

It is not the least ill consequence of all attending the routine system we would fain break through and abolish, that by excluding variety of form in plan, it likewise excludes what would else suggest fresh ideas in regard to style of fitting up, and decoration. Most undoubtedly much character may be given to a room of the simplest and most usual form, yet it is seldom done, and seems to be as seldom attempted. On the contrary, there is a certain established uniform into which rooms of the same class are put almost indiscriminately, without regard to other circumstances. This is more particularly the case with regard to dining-rooms, for which it seems to be laid down as a rule that they have as little architectural attraction as possible bestowed upon them, in fact, show little more than plain walls of a single tint. As a general rule this is, we admit, a wholesome and safe one enough, because, if it admits nothing to gratify, it excludes much that might offend the eye. The very monotonousness and plainness are, besides, characteristic in themselves, so far as such a room is thereby sufficiently distinguished from the others in a house. Still, equal distinction, we conceive, could be kept up, equal propriety of character be maintained, with far greater variety of design; because simplicity and sobriety are by no means restricted to any one mode in particular; neither is the same degree of them desirable upon every occasion. What in one case would be modest elegance, may in another prove scarcely better than chilling nakedness and monotonous dulness. Where all else is plain and unpretending, an air of quiet homeliness and even snugness is becoming enough; but where plate is profusely displayed, and all the appointments of the table are of a sumptuous kind, some corresponding degree of show in the room itself can hardly be an inconsistency. Not only cheerfulness, but festivity of appearance will be perfectly in character, care of course being taken that the particular character be distinctly in accordance with the particular purpose of the room itself. Some variety of colouring is admissible, and though we would exclude *pictures*, we would freely admit *paintings*, that is of a light decorative cast, and as subsidiary to architectural character, such as borders and narrow upright panels at intervals, with arabesques or single figures *en camaieu*, or on a marbled ground. But as to oil pictures in frames, we consider them very ill-suited for dining-rooms, notwithstanding that they are frequently to be met with in them, and are almost the only decorations that are. As far as effect goes, the frames are of more importance than the pictures themselves, which, let them be ever so worthy of examination, are not likely to obtain it, unless attention be pointedly directed to them. Oil pictures are much better adapted for morning than evening rooms; since, so far from at all showing themselves to advantage by artificial light, many of them rather give a room a sombre though rich appearance at such time, unless the room happens to be lighted up expressly for the purpose of exhibiting the pictures themselves.

But all this while we are forgetting our "Episodes," or rather our main subject, and indulging in lengthy episodical remarks grafted upon it, and from which we will now make a transition by quoting an example of a dining-room that was certainly a frequent architectural episode in the interior of Carlton House, we mean the circular one on the principal floor, for the "Gothic" dining-room at the east extremity of the lower apartments towards the gardens, was a positive monstrosity—almost as vile and trumpery in taste as can be conceived. The other was an octastyle Ionic rotunda, extended by four deep recesses or alcoves radiating to the centre of the plan, consequently expanding inwards. We are not aware of any thing similar having been done in any other room of the kind; and yet not only is the plan exceedingly beautiful in itself, but one that admits of numerous variations, to say nothing of the great diversity of design it allows and even suggests, in other respects.

By way of contrast to the plans we gave in the first instance, we now show one for a dining-room whose ends are concave and semicircular, but whose plan is of peculiar character, there being small recesses with columns, between which there is at one end of the room a third recess for the side-board, at the other a window. Any arrange-

Fig. 5.



ment of this kind would produce an unusual degree of architectural play and richness, with somewhat of intricacy, but not such as to produce confusion or disturb the regularity, if not simplicity, of the ensemble, since the individual parts and recesses are sufficiently connected together by the columns and antæ, disposed semicircularly.

The idea itself admits of being so variously shaped, of being taken as the germ of so many distinct designs, not for a dining-room alone, but for apartments of other kinds, that were we at all at a loss for subjects, we could make it serve us for a great many Episodes. For instance, supposing the plan to admit of it, the same arrangement would be exceedingly well adapted for a library or morning-room with a window at each end, the four recesses, either with or without columns, being filled up with bookshelves, and either a single door opposite the fire-place, or two doors in the angles on that side of the room as circumstances might require. Else there might be a window there as at present, and three recesses for book-cases at each end of the apartment

In regard to the plan here shown as that for a dining room, it is not proposed as one capable of being strictly followed, because it would stand in need of more or less alteration in order to adapt and adjust it, so as to combine advantageously with the rest. Of course it is here presumed that there is nothing to hinder its being executed precisely as it is represented in the cut. The door near the sideboard is supposed to open into a corridor communicating with the offices, and the other from a vestibule or ante-room, as the case might be. There are four pedestals for candelabra, and there might be others in the two arches within the recesses: these, however, are not absolutely essential to the design, but might be adopted or omitted according as more or less decoration should be held desirable,—a point to be regulated by the scale of embellishment fixed upon. The recesses and semicircular ends of the room are supposed to be floored with ornamental tiles or mosaic (like the saloon of the Reform Club), and the square or centre part to be covered with a rich carpet. Or else the whole might be carpetted, and the same kind of distinction be nevertheless kept up, by putting down plain carpetting of some quiet neutral tint at the ends, for the purpose of giving more importance to the middle compartment of the room, and to the two extreme ones somewhat the air of being spacious semicircular alcoves with smaller recesses within them. After all, however, the propriety of so doing would depend upon whether any corresponding sort of distinction between the several divisions of the room was observed in the design of the ceiling. Should the situation of the room be such as to admit of the centre being lighted from above, the ceiling might then be raised by a cove, and have a lantern occupying the rest of it. In such case no side windows would be required, still the one at the end of the room might be retained, unless it should be preferred to make a second sideboard recess corresponding with that at the opposite end, or to have these folding doors opening from an ante-room, substituting a niche for the present door in the recess on the left hand.

(To be continued.)

ON THE FORMS AND PROPORTIONS OF STEAM VESSELS.

Though reluctant to call in question the opinions of so able a writer as "H. P. H." appears to be, I think he has no authority for multiplying the "sectional *area* of the immersed parts" of a steam vessel, into the (mean) *depth* below the surface of the water, in order to find the resistance to her motion. Doubtless this would be correct for "floodgates," of which one surface only is exposed to the water, and the pressure is that arising from the *weight* of the fluid; but the case of a vessel is totally different, the resistance arising not from any weight of the fluid, (for the pressure on the after half of the vessel tending to push her forward, is exactly equal to the pressure on the fore part which tends to retard her,) but from a species of friction and from the inertia of the fluid. This resistance probably increases in porportion to the *density* of the water, not to its *depth*.

As the whole of the theoretical part of the article "On the Forms and Proportions of Steam Vessels," is founded on the presumption that the resistance is proportional to the section and depth, instead of section without regard to depth, as given in mathematical works, and as it will be completely erroneous if the above view is the correct one, it may be worth while for H. P. H. to reconsider the nature of the resistance of which he writes, and to favour the readers of the Journal with his opinions—waiting which I am,

Very respectfully,

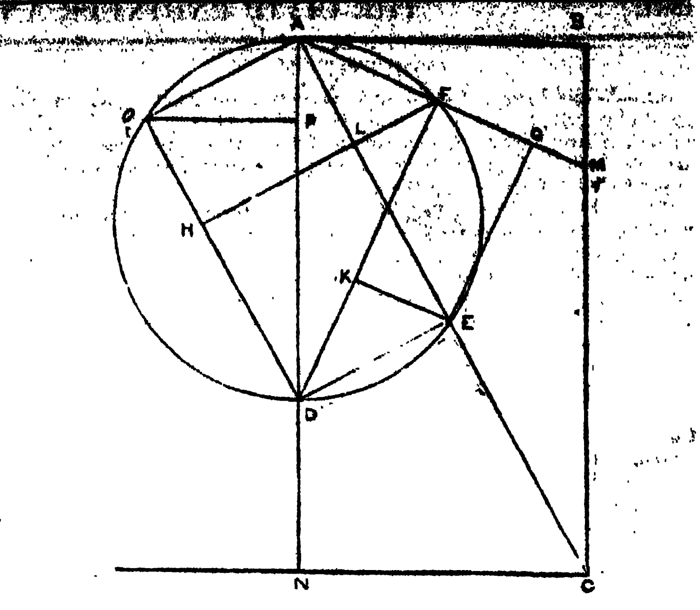
A. M.

Neath, 11th of 9th month, 1841.

ON THE STRAIN OF BEAMS.

Sir—It may be interesting to trace the effects on beams of strains acting on them in a parallel direction. In the common hand punch, for example, there is an upright beam bent at right angles at top to a convenient distance, the extremity being fitted to receive the reaction of the plates under the punch. Here the strain on the beam is upward. Instances of similar downward strains, too, are familiar, as in some portable balances, in which the scales hang from the extremity of an upright standard bent forward at the upper end.

Let A B C be an upright standard rising perpendicularly from the sole N C, and bent at right angles at B; let it be subjected to a force



acting downwards in the line A N parallel to B C. Then it would appear on a general view, that the part B C will be equally affected throughout, as the force, which let A D represent, has the same leverage on all points of B C.

But, more particularly, in estimating the action of the force on any point M, we may consider it as acting on M by the imaginary straight lever A M. The action of the force A D on M may be analysed by drawing D F perpendicular to A M; A D = A F and F D, the former being longitudinal pressure along A M, the latter, a lateral strain on the cross section at M by the leverage A M. Similar resolutions for other points in B C will form right angled triangles on the common base A D, and thus the locus of the vertices of these triangles is a circle described on the diameter A D, passing through point F, of course.

To ascertain how the forces A F, F D, acting on the section M, affect any other section, as that at the base C, draw A C cutting the circle at E, join D E, and complete the parallelogram O E; draw F H perpendicular to O D, cutting A E and O D at L and H. Then A F = A L and L F, and F D = D H and H F, these four resultants all acting at point A on lever A C; the sum of the longitudinal strains is A L + H D = A L + L E = A E; the lateral strains L F and F H, acting in opposite directions = F H — F L = H L = D E. Thus the resultants of the forces A F, F D, acting on the section M, are A E and E D on section C. But A E and E D are also the resultants of A D acting directly on section C. It appears, then, that the effect of the force A D on the section C is one, whether acting directly by A C, or indirectly by A M C. Again, the reciprocal action of the forces A E, E D, acting directly on C, upon the section M, may be had by drawing E K, E G perpendicular to D F, A M respectively. For we then have D E = E K and K D, and A E = A G and G E. Then G E or F K + K D = F D, and A G — K E or F G = A F. But A F and F D are the resultants of A D acting directly on M. Therefore, as M and C represent every two points in B C, and as the direct action of the force A D on either point is identical with its indirect action through the other point, we conclude, generally, that its action on every cross section of B C is constant, and therefore B C ought to be of equal dimensions from bottom to top. Draw O P perpendicular to A D, then A O = A P and P O, and D O = O P and P D, and as P O in these two quantities acts in opposite directions, we have A O and D O = A P and P D = A D, which intimates that there is no lateral thrust on the standard, so that the cross section of B C may at once be determined from the quantities A D, N C. The part A B ought to have the parabolic outline, modified when the corner B is rounded.

By supposing all the forces reversed in direction, the above demonstration will apply also to standards subjected to upward strains.

I am, Sir,
Your obedient servant,
Daniel Clark.

Phœnix Iron Works,
Glasgow, 20th Aug.

P.S. I think it would be a great improvement to introduce symbols to express the most common terms in papers of the nature of the preceding: ○ for *circle*, ⊥ for *perpendicular*, &c.

COMPETITIONS.

Sir—While I regret to find that so very little good, if any at all, should hitherto have been produced by all that has been said on the subject of Architectural Competitions, I am glad to perceive that you are not backward in aiding to correct the abuses now attending the present mode of conducting them.

The case stated in your last number is perfectly scandalous and flagitious, that were not the circumstances given upon Mr. Godwin's own authority, I should conceive it to be unfairly reported. And yet when I consider what sort of a design it was to which the highest premium was awarded in the first competition for the Royal Exchange,—a design that would be now utterly forgotten—had not that circumstance rendered it so memorable; when, again, I consider the result of the two competitions for the Nelson Monument, and that nothing more tasteful and original than the stale absurdity of an overgrown column could be picked out of all the designs and ideas submitted to the Committee, I am less astonished than I else should be at the *measures* which, it appears, have been taken by the "Tailors."

After especially inviting seven architects to make selection of the poorest design of all, certainly does look most awkwardly suspicious. Still, in this instance, I should say that the "honourable" Committee have perhaps done no more than act up to the very letter of their engagement, bestowing the prize on him who displayed *Superiority*—though it happened to be that of demerit.

It is some little consolation to reflect that such very flagrant instances may in time have the good effect of stiring up the profession to unite cordially and vigourously in devising such measures as should in future protect them from such swindling,—and to give it, would be almost to countenance it. Any sort of delicacy towards persons who scruple not to lend themselves to such dirty doings, would be sheer weakness. Better would it be were the names of all the parties—all the "highly respectable" individuals, concerned in such transactions, shown up to the public. A little pillorying of that kind would do a vast deal of good, and serve to render such respectable gentlemen either a little more cautious or a little more adroit. If they must be rogues there is no occasion for them to show themselves such arrant bunglers also, as they now generally do.

I remain, &c.

VINDEX.

Sir—Eventually the evils arising from the present system of public and limited competitions will work their own cure, as architects who love their profession and desire to uphold its respectability will pause ere they lend themselves to the gross jobbing, and party interest which so generally occurs on such occasions. It seems to me that as a body we are heaping insult upon our own heads by the submission of designs (generally—if not always—the result of mature deliberation), to men seldom possessing an atom of architectural taste, or any other qualification requisite to render them efficient as judges of the works placed at their disposal for acceptance or rejection. I would advise my friend Mr. Godwin to keep an eye upon the Tailors he alludes to in your last number, (page 310), as no doubt they have been at their usual dirty work, and have "cabbaged" portions from each of the designs entrusted to their care; with regard to the Paddington Church job I happen to know very little about it, but should think, if all we hear is true, that for the credit of the Committee, 'the least said is the soonest mended."

Having myself done with public competition, I may be permitted to add my opinion that architects competing should do so only upon the understanding that members of their own body should be their judges, as regards the comparative architectural merit and fitness of the several designs, and the more fairly to do so I would suggest that each candidate in turn should examine and compare the designs, and omitting his own, should give in a written opinion upon their several degrees of excellence; the decision thus come to could hardly fail in being a just one, while by this means the first, second and so forth would be pointed out without any chance of favouritism, and each of the judges having in his own case been compelled to study the whole work minutely, he would thus be the better qualified to give an opinion upon the productions of others; this proposal no body of persons advertising for designs could reasonably object to, if they wish to have erections throughout the land, which are to remain monuments of the talents of their respective architects, and of their own taste in expending the means committed to their disposal.

The success of some of the profession, who (like itinerant vendors of tea, millinery, &c.) scour the country in the various directions pointed out by the public advertisements, and earwig the Committees, they induce them for a time to follow up competition as a thriving trade; but I feel assured such a system cannot last, it only requires those architects who honour their profession, to unite in upholding its respectability, by refusing to enter into any competition unless it is regulated in some equitable and consistent manner, and in the long run they must succeed. The two last competitions that I had any thing to do with were the Infant Orphan Asylum and the Tower of Wandsworth church, at the first the architects were limited to 20,000*l*. as about the sum to be expended, and in order that this stipulation should be attended to, all the parties competing were required to furnish detailed quantities of their several designs, in defiance of this stringent clause, which of course sate like an incubus upon the ideas of the greater number who sent in—a design was chosen, the lowest tender for the execution of which was about 33,000*l*.; in this case two premiums were offered, one of 100 guineas and one of 50 guineas, the second of which only was awarded, thus: those who conformed to the printed regulations were excluded from participating in the first premium, while those who did not reaped the whole benefit; and I maintain that the Committee were bound in justice to those who obeyed the instructions, to have awarded both premiums, if to please themselves they chose to execute a more expensive design.

In the second case, namely, that at Wandsworth, the present Tower of the Church being in a very dilapidated state, the parish deemed it necessary that something should be done, and the result of their deliberations was that architects should be invited to send in plans, &c. for a new Tower, to cost 1,000*l*., which sum they were willing to expend: but lo! when the designs came before them, they, contrary to the above case, considered economy to be the order of the day, and they in consequence awarded their premium to a design to cost 500*l*. only, and thus again those who conformed were laid on their backs, but it did not rest here, for after their economical decision in came the *extreme* economists of various denominations unconnected with the church, and at a subsequent meeting decided on curtailing the edifice of its intended fair proportions, by actually carrying a resolution to repair the already condemned and ruinous old Tower, at a still less expense; but the tables are turned, the work (I am given to understand) is stopped, the builder is afraid to proceed, and the architect refuses or rather suspends any other opinion but that he is to complete his contract; thus the parish are literally in a pretty situation between two stools, and have no one to thank but themselves. While from the want of rule in competitions as shown in the above cases, the profession never have any guarantee that their productions will be judged by any uniform and equitable rule, but find themselves put out of court sometimes because they are not sufficiently gorgeous, and sometimes because they are too expensive, while in both cases they have strictly conformed to the instructions given.

I am, Sir, your obedient servant,

JOHN BURGES WATSON.

39, *Manchester Street, Manchester Square, September* 7, 1841.

Sir—Reading in your valuable Journal for this month, some curious statements respecting "Competition Designs." I beg to state a case which happened to me some time since at Shrewsbury, which I think will surpass, in richness of facts, any I have yet read about.

A premium of 10*l*. was offered, publicly, for the best plan of a chapel to be erected near the town of Shrewsbury. The vestry were to be the judges.

They met at the publicly advertised time, and selected my design, and their officer informed me of the fact.

Not hearing any thing more about the matter for some time, I called at the vestry-room, and inquired how things were going forward.

And, Sir, what do you think was the answer I received, from the same functionary who had previously charmed my heart by giving the information previously stated? A cheque for the 10*l*. was—*not* handed over; nor was any order from the vestry given for me to proceed with the work. But still—"something" was given me which astounded me equally with either, and that was a grave address from the aforesaid officer, in the following words:—They have now given the premium to ———.* My feelings were of course those of surprise and astonishment, and almost *disbelief*; but the latter was soon expelled on receiving from my informant the *reasons* which actuated the "vestry." "The fact is this, Mr. —— assured some of our vestry that if they thought proper to give the premium to him, he would hand it over to one of the town charities, and they thought as how they could not commit a a nobler hact." This you will say *was* a noble act.

Your's, truly,

VERITAS.

* An architect who lived in the town and parish.

NEW ACTS OF PARLIAMENT.

There have been introduced, by Lord Normanby (the late Secretary of State) into the Houses of Parliament, three very important Bills connected with the profession, which demand their immediate and especial attention. The bills are too long to be transferred entirely into our Journal, but we shall give an abstract of the most important clauses in each Bill, which will show their general character.

REGULATION OF BUILDINGS IN LARGE TOWNS.

Abstract of a Bill intituled "An Act for regulating Buildings in large Towns," which has passed the House of Lords, and is now before the House of Commons.

1. Whereas disease is engendered and aggravated by the crowded and unhealthy manner of building the dwellings of the working classes in the large towns and populous places of this realm, and it is expedient to make provision for improving such dwellings: be it therefore enacted, &c., That the council of every borough which is within the provisions of an act passed in the sixth year of the reign of his late Majesty, intituled "an Act to provide for the Regulation of Municipal Corporations in England and Wales," or of any charter granted in pursuance of that or any subsequent act, and of every borough which is within the provisions of an act passed in the fourth year of the reign of her Majesty, intituled "an Act for the Regulation of Municipal Corporations in Ireland," and the magistrates and councils of every royal burgh and parliamentary burgh in Scotland, and of every burgh of barony or of regality in Scotland under the government of magistrates and councils, and also in England and Ireland the justices of the peace in general or quarter sessions assembled, and in Scotland the sheriff, having jurisdiction in any other town or place which her Majesty, with the advice of her privy council, shall order to be within the provisions of this act, shall, within six calendar months next after the passing of this act, or next after such order, and from time to time as vacancies shall happen, appoint a fit person, or so many fit persons as the council or justices or sheriff respectively shall think fit, not being surveyors of the estates of the mayor, aldermen, and burgesses of any borough, or of the corporation of any burgh, in which they are appointed, to be surveyors of buildings in such borough, town, or place, and to see that the several provisions of this act are observed therein; and each of the said surveyors shall have in his special charge such district of the borough, town, or place for which he is appointed as the council or justices or the sheriff shall in that behalf appoint; and each of the said surveyors shall hold his office during the pleasure of the council or justices or sheriff by whom he is appointed, and may, if the council or justices or sheriff shall so think fit, but not otherwise, have an assistant or assistants under him (such assistants being in all cases appointed by and holding their situations during the pleasure of the council or justices or sheriff); and the council or justices or sheriff shall have authority to fix the districts in which the said surveyors are to act within the borough, town, or place, and to do all things relating in anywise to the appointment and direction of such surveyors and assistant surveyors: provided always, that if a charter of incorporation shall be granted to any town or place in which such surveyors or assistant surveyors have been appointed, the future appointment of such surveyors and assistant surveyors shall be vested in the council, as if such town or place were incorporated at the time of the passing of this act.

2 and 3 enacts, that surveyors are to make declaration, to diligently, faithfully, and impartially perform the duties of the office; the council or justices or sheriff shall provide an office for the said surveyors.

4, Surveyors to be paid by fees, not exceeding for a first rate building 3*l.* 10*s.*, second rate 3*l.*, third rate 2*l.* 10*s.*, fourth rate 2*l.*, fifth rate 1*l.* 10*s.*, sixth rate 1*l.*; and for every alteration or addition to any building, a sum not exceeding half the above.

5, Powers given to councils of boroughs by this act to be exercised in Oxford by commissioners under act 11 G. 3, for improving the city of Oxford.

6, The surveyors appointed under any of the acts specified in the schedule (London, Bristol and Liverpool), shall be the surveyors for enforcing so much of this act as is to be enforced within the limits of the said several acts, and shall be entitled to receive for their trouble herein such additional fees as shall be ordered and settled by the authority by which they are appointed.

7, Notice of building or altering premises to be left at the surveyor's office.

Clauses 8 to 15, regulations for fees, duties of surveyors, penalties for default of notice, workmen offending and refusing inspection.

16, That it shall not be lawful to build within the limits of this act any house in which the floor of any room or cellar to be used as a dwelling* shall be below the surface or level of the ground in the immediate neighbourhood of such house, unless there shall be an open area not less than three feet wide from the floor of such room or cellar to the top of the area adjoining to the front or back of such room or cellar, and extending from one side or party wall to the other side or party wall; but this enactment shall not be taken to prevent any archway or covering which may be laid across such area for the purpose of approaching the doorway of the house.

* We consider that the words here used require to be particularly defined. If they mean any room that is used for domestic purposes, such as a kitchen forming part of a dwelling house, the act will then effect a very serious injury on nearly half the houses in London; if dwelling mean a room wherein any person sleeps, then we do not see any objection to the Act, but in such case it would be better to alter the word *dwelling* to *sleeping room*.—Editor.

17, That in any house to be built within the limits of this act after the passing thereof it shall not be lawful to let separately, except as a warehouse or storehouse, or to suffer to be occupied for hire as a dwelling place,* any underground cellar or room not having a window and fireplace, as well as such an open area adjoining thereunto, as is herein-before specified.

18, Enacts, that in any house built within the limits of this act before the passing thereof it shall not be lawful to let separately, except as a warehouse or storehouse, or to suffer to be occupied for hire as a dwelling place, after the first day of January 1845, any underground cellar or room not having a window, or after the first day of January 1848, any underground cellar or room not having, in addition to such window, such an open area not less than two feet wide, as is herein-before described, or after the first day of January 1851, any underground cellar or room not having a fireplace in addition to such window and area.

19, Enacts, that every person who shall wilfully let or suffer to be occupied any underground cellar or room contrary to the provisions of this act shall forfeit and pay the sum of 20*s.* for every day that such cellar or room shall be so occupied, to be recovered by action of debt, either by the person occupying such cellar or room, or any other person who will sue for the same.

20, Enacts, that on any *new foundation* within the limits of this act it shall not be lawful to build any house, except corner houses, and houses built in a street or thoroughfare which was begun or laid out, before the passing of this act, under the authority of any act of parliament, unless there shall be a clear space of at least 20 feet wide between the back wall of such house and the back wall of any opposite house: provided always, that in estimating this distance no account shall be taken of any back addition or outbuilding belonging to either of such houses not more than half the height of the back wall of the house above the level of the street, and which addition or outbuilding shall not extend along more than two-thirds of the whole width of the house to which it belongs; but no such addition or outbuilding shall be nearer than seven feet to any other house, or to any addition or outbuilding to any other house, except privies, sheds, or other buildings, not more than eight feet high above the level of the street which may adjoin the fence or fence wall on either side.

21, Enacts, that it shall not be lawful to build any new street, alley, or public passage within the limits of this act, except such as were begun or laid out before the passing of this act, under the authority of any act of parliament, unless the houses therein shall be separated by at least 30 feet where there is a carriageway between such houses, or at least 20 feet in the case of alleys and foot passages where there is no carriageway.

22, Enacts, that it shall not be lawful to build within the limits of this act any new court or alley (except mews and stable yards) narrower than 30 feet, through which there shall not be an open passage at each end thereof at least 20 feet wide, and entirely open from the ground upwards.

23, Enacts, that the level of ground floor of every house which shall be built within the limits of this act shall be at least six inches above the level of the footway or road adjoining such house.

24, Enacts, that no room which shall be built within the limits of this act to be used as a dwelling on the cellar or ground floor, or elsewhere than in the upper story of any third rate house, or any house of a lower class or rate than the third, as defined by the said several acts named in the schedule (London, Bristol and Liverpool), within the limits of the said acts respectively, and elsewhere as defined by this act, shall be less than eight feet in height from the floor to the ceiling, and no room in the upper story of any such house shall be less than seven feet in height from the floor to the ceiling.

25, That there shall not be more than one story in any part of the roof of any house or other building which shall be built within the limits of this act.

26, That no third rate or lower rate of house, defined as aforesaid, except houses in a street or thoroughfare which was begun or laid out, before the passing of this act, under the authority of any act of parliament, shall be built within the limits of this act without an enclosed yard, which, exclusive of any buildings therein, except the privy (if any), or any shed or other building not more than eight feet high, shall be of the extent of one-sixth part at least of the ground covered by the house; and no house shall be built within the limits of this act without a privy, with proper doors and coverings to the same, either in the house, or in the yard attached to the house, and sufficiently screened and fenced from public view, to the satisfaction of the surveyor of the district.

27, All buildings erected contrary to this act to be abated.

28, Provides for preventing neglect or evasion of this act.

29, And whereas it is expedient that further provisions for security against fire should be made in such boroughs and towns as aforesaid which are not within the provisions of any of the acts named in the said schedule (London, Bristol and Liverpool); be it enacted, that all buildings begun to be built or rebuilt in any such borough or town not within the provisions of one of the said acts shall, after the passing of this act, be built and rebuilt according to the regulations herein-after contained, and the outer walls, party walls, separate side or end walls, chimney backs, and chimney flues shall be built according to the schedule (A.) annexed to this act: provided always, that where there is more than one story below the level of the street the walls of the lowest story shall be half a brick or four inches and a half thicker than is otherwise required.

The remainder of the clauses apply to provincial towns, and are framed somewhat similar to the Metropolitan Building Act. The annexed schedule explains the thickness of the walls and the classes of buildings.

SCHEDULE (A).

DESCRIPTION OF BUILDINGS.	THICKNESS OF OUTER WALLS.				THICKNESS OF PARTY WALLS.*				
	In Cellar Story to under side of Ground Story Floor.	In Ground Story to the top of joists in floor above Ground Floor.	Above to the top of the Wall, or, if a Parapet, to the upper side of the ceiling of the Top Story.	Parapet.	In Cellar Story to under side of Ground Story Frost.	In Ground Story to the top of joists in floor above Ground Story.	Above to the top of joists in floor above First Story.	Above to under side of the ceiling of the Top Story.	Above through the roof to the Top.
First Rate. Every Church, Chapel, and other Place of Public Worship, Brewery, Distillery, Manufactory, Warehouse and other Building (not being a Dwelling House or a Building in the Fifth or Sixth Class) which is higher than 31 feet. Every Dwelling House which is higher than 50 feet, or which contains more than nine squares of building on the Ground Floor—every Dwelling House or other Building which has more than three clear stories above ground.	2 B. or 17½ In.	2 B. or 17½ In.	1½ B. or 13 In.	1 B. or 8½ In.	2½ B. or 22½ In.	2 B. or 17½ In.	2 B. or 17½ In.	2 B. or 17½ In.	1½ B. or 13 In.
Second Rate. Every Warehouse or other Building (not being a Building in the First, Fifth, or Sixth Class, or a Dwelling House,) which is higher than 22 feet, or which has three clear stories above ground. Every Dwelling House (having three clear stories and no more above ground) which is higher than 40 feet, and every Dwelling House which contains more than five and not more than nine squares of building on the ground floor.	1½ B. or 13 In.	1½ B. or 13 In.	1 B. or 8½ In.	1 B. or 8½ In.	2½ B. or 22½ In.	2 B. or 17½ In.	2 B. or 17½ In.	1½ B. or 13 In.	1½ B. or 13 In.
Third Rate. Every Warehouse and other Building (not being a Dwelling House or a Building in the first, second, fifth, or sixth class,) which is higher than 13 feet, or which has two clear stories above ground. Every Dwelling House (having three clear stories and no more above ground) which is higher than 37 feet. Every Dwelling House which contains more than three squares and a half, and not more than five squares of building on the ground floor.	1½ B. or 13 In.	1½ B. or 13 In.	1 B. or 8½ In.	1 B. or 8½ In.	2 B. or 17½ In.	1½ B. or 13 In.	1½ B. or 13 In.	1½ B. or 13 In.	1½ B. or 13 In.
Fourth Rate. Every Warehouse and other Building (not being a Building in the first, fifth, or sixth class,) which is not higher than 13 feet. Every Dwelling House (having two clear stories and no more above ground) which is higher than 25 feet. Every Dwelling House which has not more than one clear story above ground, or which does not contain three squares and a half of building on the ground floor.	1½ B. or 13 In.	1 B. or 8½ In.	1 B. or 8½ In.	1 B. or 8½ In.	1½ B. or 13 In.	1½ B. or 13 In.	1½ B. or 13 In.	1½ B. or 13 In.	1 B. or 8½ In.

Fifth Rate.

Every Building (not being a Building of the first class or a Dwelling House) which is at least four feet and not more than ten feet from any Public Street, Road, or Way, and at least sixteen feet from any other Building not in the same possession, or connected with any such Building only by a fence or fence wall, may be built of any dimensions, but must be built either of brick or stone, or covered with incombustible materials.

Sixth Rate.

Every Building, not in the first class, which is at least ten feet from any Public Street, Road, or Way, and at least thirty feet from any other Building not in the same possession, or connected with any such Building only by a fence or fence wall, may be built of any dimensions and with any materials.

* Separate Side or End Walls between Buildings shall not be less than the length of one brick or 8½ inches thick, or, when the wall is higher than 24 feet, less than the length of one brick and one half, or 13 inches thick.

Where any Building is not founded on rock, every Outer or Party Wall shall have at least four footing courses below the level of the Cellar floor, each two courses projecting 2¼ inches on each side of the course or wall immediately above them; and all Inner Walls shall have at least two footing courses 4½ inches wider than the wall above them; and all such footings shall commence upon a firm natural or artificial foundation to be approved by the Surveyor.

DRAINAGE BILL.

Extracts from a Bill intituled "An Act for the better Drainage of Towns and Villages," which has passed the House of Lords, and is now in the House of Commons.

1. WHEREAS there is great need of sanatory regulations in the towns and opulous places of this realm, especially for want of sufficient means of rainage, whereby disease is engendered and aggravated; be it therefore nacted, &c., that after the passing of this act it shall not be lawful to build ny house within the limits of this act, unless a drain be first constructed to ne satisfaction of the commissioners of sewers having jurisdiction there, of uch material, size, level, and fall as they shall direct, which drain shall lead om the intended site of such house to such common sewer, common drain, r common watercourse as the commissioners shall direct, or if there be no uch common sewer, common drain, or common watercourse within 10 yards f any part of the intended site of such house, then to such cesspool or other lace as the commissioners shall direct, not more than ten yards from some art of such intended site.

2. That in all cases where any house built within the limits of this act, ither before or after the passing thereof, shall not be drained by a sufficient rain communicating with some common sewer, common drain, or common vatercourse, to the satisfaction of the commissioners of sewers, and if a ewer, drain, or watercourse of sufficient size, under the jurisdiction of the ommissioners of sewers, and which they shall think fit to be used for draining such house, shall pass along any public thoroughfare or way in front of r behind any part of such house, it shall be lawful for the said commissioners o give notice in writing, signed by any surveyor or officer appointed by them or that purpose, to the occupier of such house, requiring such occupier or he owner thereof forthwith, or within such reasonable time as shall therefore be appointed by the said commissioners, to construct a covered drain of uch materials, size, level, and fall as the commissioners shall direct, from he said house to the said sewer, drain, or watercourse; and if the owner or ccupier of such house shall refuse or neglect, during 28 days next after the aid notice shall have been delivered to such occupier or left at such house, o begin to construct such drain, or shall thereafter fail to carry it on and omplete it with all reasonable despatch, it shall be lawful for the said commissioners to construct the same, and to recover the expences to be incurred hereby by distress and sale of the goods and chattels either of the owner or f the then present or any future occupier of such house as herein-after mentioned, by warrant under the hands and seals of six or more or the said commissioners.

3. That whenever any house shall be rebuilt within the limits of this act, he level of the lowest floor shall be raised sufficiently to allow of the contruction of such a drain as is herein-before provided in the case of houses to e built after the passing of this act, and for that purpose the levels shall be aken and determined under the direction of the commissioners of sewers; nd whenever any house shall be taken down as low as the floor of the first tory, for the purpose of being built up again, such building shall be deemed a rebuilding within the meaning of this act.

4. The level of every new street, court, alley, and place which shall be nade, and also the level of every street, &c. in which any new common sewer or common drain shall be made, shall be fixed under the direction of the commissioners of sewers.

5. The commissioners of sewers shall have authority, from time to time, as hey shall see fit, to widen, deepen, embank, alter, arch over, amend, clean, nd scour all or any of the sewers, drains, watercourses, sinks, vaults, cesspools, and privies within their jurisdiction, and also to cleanse, drain, amend, nd abate all stagnant ponds and other nuisances whereby the health of the neighbourhood is or is likely to be affected, and to make new sewers, drains, sinks, cesspools, or vaults where none formerly existed, and also to make reservoirs, engines, sluices, penstocks, or any other works for better draining any place within their jurisdiction, in, under, or across all or any of the public ways, thoroughfares, or places within their jurisdiction, and, if needful, through nd across all underground cellars and vaults which they shall find under any of the said public ways and thoroughfares, doing as little damage as may be, nd making due compensation for the damage done to the owners and occupiers thereof; and in case it shall be found necessary, for completing any of of the aforesaid sewers or drains, to build, carry, and continue the same into nd through any inclosed lands or other place, not being a public way, it shall be lawful for the said commissioners to build, carry, and continue the same into or through the said lands or other place accordingly, making due compensation to the owners and occupiers thereof; and all such sewers and other works and premises shall be at all times under the control, care, and management of the said commissioners, and of their surveyors and officers.

6. It shall be lawful for the commissioners of sewers, at their discretion, to abandon any common sewer or common drain running through narrow courts or alleys of houses or inclosed places, or through or under any place not being a public way, in all cases wherein a new common sewer or common drain shall be constructed, in any public streets, roads, or highways contiguous thereto, and capable of receiving the drainage of such courts, alleys, or inclosed or other places; and that upon such drainage being turned into such new sewer or drain the said commissioners shall not thereafter be obliged to maintain the sewers or drains so to be abandoned, but shall order the same to be filled up at their discretion, and that all branch drains communicating with any sewer or drain so to be abandoned shall be turned by the owners of the lands and tenements theretofore drained thereby into the new sewer or drain to be constructed instead of such abandoned sewers or drains, by making drains into such new sewers or drains, conformably to the regulations of the commissioners of sewers: provided always, that if such new sewer or drain shall not be brought within the distance of ten yards from the lands or tenements formerly drained by the abandoned sewer or drain, the cost of completing the branch drains beyond the length of 10 yards shall be defrayed by the commissioners of sewers.

7. Commissioners to give 28 days notice and provide a plan and section before making any new common sewer or common drain under this act, where no common sewer or common drain already existed, and before abandoning any old common sewer or common drain, and before abating any such nuisance as aforesaid.

10. That before making any drain or watercourse for the purpose of draining water directly or indirectly from any land or tenement into any common sewer, &c., and also before beginning to lay or dig out the foundations of any house therein, or to rebuild any house therein, 14 clear days notice in writing shall be given to the commissioners; such new drain or watercourse shall be made of such materials and workmanship, and laid at such level, as is provided by this act, and under such regulations as the said commissioners shall order.

11.* That it shall be lawful for the commissioners, or for their surveyor or such other person as they shall appoint, to inspect any drain or watercourse within their jurisdiction, and for that purpose *to enter at all reasonable times, by themselves, or their duly authorized surveyors, officers, and workmen, upon any lands and tenements, and also to cause the ground to be opened in any place they shall think fit*, doing as little damage as may be; and if such drain or watercourse shall be found to be made to the satisfaction of the commissioners, they shall cause the same to be closed and made good as soon as may be; and the expences of opening, closing, and making good such drain or watercourse shall be defrayed by the said commissioners out of the rates and assessments authorized to be made by them by the laws in force relating to sewers.

12. That all branch drains, *as well within as without the lands and tenements* to which they belong, and all watercourses used for drains, and all privies and cesspools, within the limits of this act, shall be under the survey and control of the said commissioners, &c., and shall be repaired and cleansed at the cost and charge of the owners or occupiers of the lands and tenements to which the same shall belong; and if the owner or occupier of any land or tenement to which any branch drain, watercourse, cesspool, or privy shall belong shall neglect to repair or cleanse the same in the manner required by the said commissioners, during 14 days after notice in writing for that purpose, signed by any such surveyor or officer, shall have been given to such occupier, or left upon the premises, it shall be lawful for the said commissioners to order such branch drain, &c., to be repaired and cleansed, and to levy and recover the costs and expences thereof by distress, &c., either of the owners or of the occupiers so neglecting to repair and cleanse the same.

21. Commissioners shall cause a map to be made of the district within their jurisdiction, on a scale not less than one inch to 400 feet, and to mark thereon the course of every common sewer, common drain, and common watercourse, and shall cause the same from time to time to be altered and amended; and such map, or a copy thereof, with the date expressed thereon of the last time at which it shall have been so amended, shall be kept in the office of the commissioners, and shall be open at all seasonable hours to the inspection of the owners or occupiers of any lands or tenements within the jurisdiction of such commission.

25. Where any common sewer or common drain shall be made by the said commissioners, under any public way where no common sewer or common drain formerly existed, the cost of making the same shall be borne, in the manner herein-after specified, by the several owners of the lands and tenements abutting on such public way on either side thereof, in proportion to the several lengths of frontage so abutting;† and it shall be lawful for the commissioners, when they shall have undertaken the construction thereof, to charge the said several owners with the cost of constructing a common sewer of the usual size‡ in the jurisdiction of the commissioners, to be paid by *five equal yearly instalments*, the first instalment being payable as soon after the completion of the work as the commissioners shall require the same.

26. And whereas by the laws in force relating to sewers the commissioners are empowered to lay separate and distinct rates, as occasion shall require, for every separate and distinct level, valley, or district within their commission, or for any part thereof, whenever they shall think fit to do so; be it enacted, that so much of the cost of making any common sewer or common drain above the usual size which shall exceed the charges herein-before laid upon the several owners of lands and tenements abutting on any public way, and also the costs of making those parts of any common sewer or common

---

* Clauses 11 and 12 contain very extraordinary powers, and such as are liable to be used with great abuse.—EDITOR.

† For corner houses there ought to be some provision, so as to make them chargeable for one frontage only, and not as is now the case for two frontages. —EDITOR.

‡ We consider that the commissioners ought not to have the power for charging or enforcing in any case more than for what is considered in London as a *second size* sewer. If a *first rate sewer* be constructed, the extra price ought to be chargeable to the whole district drained by it, as provided in the following clause.—EDITOR.

drain which cannot be charged upon any particular owner of lands and tenements, and of widening or deepening any common sewer or common drain already existing, and of repairing and cleansing each common sewer and common drain when made, shall be borne by the owners of all lands and tenements within the level, valley, or district, or part thereof, for which such separate rates are made, wherein such common sewer or common drain is situated.

29. That, subject to the provisions herein contained, the instalments payable for making any common sewer or common drain, and all rates which the commissioners are empowered to assess and shall assess upon any lands or ments within their jurisdiction, shall be recoverable, if not paid, by distress, &c. either of the owner or of the then present or any future occupier of such lands and tenements.

30. No occupier of any land or tenement for a less term than from year to year shall be required to pay, more than the whole amount of rent which was due and payable from him at the time when the notice herein-before mentioned in each case shall have been delivered to him, or left upon the premises as aforesaid, or which shall thenceforth from time to time accrue and become payable by him, unless he shall neglect or refuse, upon application made to him for that purpose by or on behalf of the commissioners, truly to disclose the amount of his rent, and the name and address of the person to whom such rent is payable; but the burden of proof that the sum demanded of any such occupier is greater than the rent which was due by him at the time of such notice, or which shall have since accrued, shall lie upon such occupier.

31. In every case in which any tenant or occupier shall have paid any sum for making, repairing, or cleansing any common sewer, &c., or for making or repairing any branch drain, or any cesspool or privy, in respect of his occupation of such lands or tenements, he shall be entitled to deduct from hi rent such part of the amount so paid by him as is herein-after specified; (that is to say,) if at the time of such payment he is a tenant for an unexpired term of 7 years, or any less term, he may deduct the whole amount paid by him; if for more than 7 years and not more than 14 years, he may deduct ¾ thereof; if for more than 14 years and not more than 21 years, he may deduct ⅝ thereof; if for more than 21 years and not more than 28 years, he may deduct ⅜ thereof; if for more than 28 years and not more than 35 years, he may deduct ⅛ thereof; but if for more than 35 years, he shall not be entitled to deduct any part thereof: provided always, that any tenant under a lease containing a covenant for renewal thereof shall be deemed a tenant for the full term to which his holding may be extended under such covenant; and that every tenant for a term depending upon a life or lives shall be deemed a tenant for such absolute term of years as shall be of the same value as such contingent term, according to the government tables for the purchase of life annuities; and every lessor, being himself also a tenant or lessee of any lands or tenements, from whose rent any part of the amount so paid to commissioners shall have been deducted, shall be entitled in like manner to deduct from the rent payable by him to his lessor such part thereof as according to the provisions herein-before contained he would have been entitled to deduct from his rent had he paid to the commissioners as aforesaid the sum so deducted from the rent payable to him; and the receipt of the commissioners, or of their treasurer or clerk, duly authorized in that behalf, shall be in each case a sufficient discharge for so much of the rent as is hereby authorized to be deducted: provided always, that nothing herein contained shall be taken to affect any special contract between any lessor and tenant or occupier of any lands or tenements, whereby it is agreed that the tenant or occupier shall defray the charges of making, repairing, or cleansing all or any sewers, drains, cesspools, and privies belonging thereunto.

40. And be it enacted, that the limits of this act in England shall be the city of London; every place within six miles in a straight line from St. Paul, and also within the jurisdiction of any commission of sewers now in force for any part of the counties of Middlesex or Surrey, during the continuance of such commission; and also every place in England within the jurisdiction of any commission of sewers which shall be duly issued after the passing of this act, by letters patent, wherein it shall be expressly declared that such commission is issued in furtherance of the provisions of this act.

41. After the passing of this act it shall be lawful for her Majesty, &c., to issue commissions of sewers in furtherance of this act for any part of Ireland.

42. And be it enacted, that this act shall extend to Scotland, and shall include all royal and parliamentary burghs, burghs of barony and regality, and also all towns and villages in Scotland which her Majesty with the advice of her privy council shall from time to time order to be within the provisions of this act.

IMPROVEMENT OF BOROUGHS.

There is a Bill now before the House of Commons intituled "an Act for the improvement of certain Boroughs," which act is to grant powers for opening and widening close and narrow streets, alleys, passages and places therein, and for otherwise improving the town, such powers to be vested in the councils of such boroughs, under certain restrictions. The following clause is the most important, and explains when the council is empowered to take lands compulsory.

4. And be it enacted, that in any of the following cases the council shall be empowered, if they think fit, to take any lands which they shall require for the purposes of this act, with or without the consent of the several owners and other persons interested therein, subject nevertheless to the provisions for ascertaining and giving compensation for the value of such lands, and for the other purposes herein-after contained; (that is to say,)

1. When any such lands are needed for the purpose of opening a thoroughfare through any court or alley which is closed at either end:
2. When any such lands are needed for the purpose of widening any thoroughfare which is narrower than 20 feet:
3. When any such lands project 10 feet or more beyond the general line of the street:
4. When the council shall have agreed with the owners thereof for the absolute purchase of the lands on each side of the lands so required to be taken, the value of those already agreed for being at least 10 times the value of those not agreed for:
5. When any such messuages or tenements built before the passing of this act are contrary to the provisions of an act passed in this session of parliament, intituled "an Act for regulating Buildings in large Towns and Villages," and are not amended according to the provisions of the said act within six calendar months after notice thereof given by the council to the owner or occupier thereof:

Provided always, that it shall not be lawful for the council to take any such messuages, lands, or tenements, without the consent of the owners and other persons interested therein, unless with the approval of the commissioners of her Majesty's woods, forests, land revenues, works, and buildings.

NEW HOUSES OF PARLIAMENT.—VENTILATION, &c.

The following is a copy of the correspondence for the warming and ventilation of the two Houses of Parliament, laid before Parliament.

Office of Woods, Aug. 27, 1841.

SIR—The progress of the works at the new Houses of Parliament, and the necessity of laying down the foundations on which the flues for warming and ventilating the houses are constructed, induced me to desire Mr. Barry and Dr. Reid to make a joint report on these subjects, by which it appears that a sum of 86,000*l*. will be required for warming, ventilating, and securing the buildings from fire, according to the following statement:—

Ventilating tower		£20,000
Air and chimney flues in the walls		12,320
Apparatus		12,000
		£44,320
For securing the buildings from fire—		
Fire-proof floors under the roof	£20,680	
Brick floor on iron beams between the principal and upper stories	21,000	
		41,680
		£86,000

I must observe, that in this sum Mr. Barry has included the sum of 20,000*l*. for a centre tower, not intended in the original plan, but which will be so constructed as to suit Dr. Reid's new system of ventilation, which he considers will be a great addition to the beauty of the structure. I am unwilling to recommend so large a sum to the Treasury without the sanction of Parliament, although a considerable part will be necessary under any circumstances, if the houses are to be warmed and ventilated on the system adopted by Dr. Reid in the present temporary houses, and which appears to me to give general satisfaction.

From the prices at which contracts have been taken for the works already in progress, there can be no doubt, with care and attention, that a considerable saving will take place on the original estimate that was sanctioned by the committee of the two houses; and I therefore request you to bring the subject before the House of Commons, as the state of the works makes it necessary that some decision should be come to without delay; I will only add, that no unnecessary delay has taken place in bringing this subject forward, and that Dr. Reid has delivered in his estimate as soon as the state of the works allowed him to do so.

I have, &c.,

DUNCANNON.

The Right Hon. F. T. Baring, &c.

Westminster, Aug. 21, 1841.

MY LORD—I beg to submit for your Lordship's consideration, a drawing of the river front of the new Houses of Parliament, showing the effect of a central tower of the height and diameter required by Dr. Reid for the purpose of ventilation, according to his first suggestion; and I have no hesitation in expressing my opinion, that the adoption of such a feature in the design would considerably improve the general effect and importance of the intended building.

I have, &c.,

The Viscount Duncannon.

CHARLES BARRY.

Whitehall Treasury Chambers,
Sept. 14, 1841.

T. F. FREMANTLE.

PROFESSIONAL CHARGES.

Vignolles v. Lefroy.

At the last Summer Assizes held at Liverpool, August 30, the following important action was tried against the Hon. Thomas Lefroy, M.P., as one of the directors of the Central Irish Railway Company, to recover compensation for work and labour performed by the plaintiff as an engineer.

Mr. Dundas, Mr. Martin, and Mr. Watson were for the plaintiff; Mr. Cresswell, Mr. Wortley, and Mr. Cleersby for the defendant.

The details of the case were long and tedious, but the following were the principal facts:—

It appeared in the case for the plaintiff, that, in the year 1836 a number of gentlemen, connected with Ireland, were of opinion that a railway from Dublin to Sligo, running through the centre of the island, would be a desirable undertaking. Of these, the defendant was one of the most active. Preliminary meetings were held, prospectuses issued, the usual staff appointed, and other measures taken for carrying the project into execution. A provisional committee was formed, at whose meetings the defendant usually attended, and very frequently took the chair. The meetings took place, whether in London or Dublin, usually at the offices of Messrs. Young, Murdoch, and Leahy, solicitors to the company. The services of an engineer being required, some discussion took place on the appointment. A person of the name of Walker was mentioned, but it was afterwards decided, very much at the instance of the defendant, that the plaintiff, who had been the engineer of the North Union, the Midland Counties, and the Dublin and Kingstown Railways, should be requested to undertake the office. The solicitors for the company communicated with him, and he accepted the situation on the 4th of June. Immediate steps were taken for completing a survey, and a number of Mr. Vignolles's pupils and assistants were set to work upon the line. He himself paid frequent visits to Ireland in superintendence of the work up to the 21st of September, during which time frequent meetings of the committee had taken place in London and Dublin, at which the defendant presided, and on which occasions resolutions were come to as to the course which should be adopted, and the measures which should be taken in advancement of the project. One subject of discussion was, the site for the Dublin terminus, and on this point some correspondence took place between the plaintiff and the defendant with reference to a meeting to discuss the matter in Dublin, and the course which should be adopted respecting it. In one of these letters the defendant says, that the terminus at Kilmainham would not go down with the Dublin people, and that he must rely upon the skill and industry of Mr. Vignolles to select a better one. On the 21st of September a meeting of the committee took place, at which the possible appointment of Mr. Vignolles to the office of engineer to the Irish Railway Commission was brought under their notice, and it was agreed that his name should cease to appear as the engineer to the company, being replaced by a Mr. Nimmo, one of his assistants, who had previously been carrying on the survey under his superintendence. It was, however, for the plaintiff, alleged that he continued really to superintend the work as before, and that Mr. Nimmo was acting under him, and not as an independent engineer. The plaintiff went to Ireland repeatedly, and carried on a correspondence with Mr. Nimmo when in England. The work was then completed, the surveys made, and the necessary maps and books of reference deposited in the Parliamentary offices. Mr. Nimmo died in 1839. The present action was brought by Mr. Vignolles for the balance due to him for these engineering services. He had received 500*l.* His charge was 40*l.* per mile on a line of 126 miles. Much more, it was said, had been surveyed, including the lines which had been abandoned as not eligible.

For the defendant it was contended that there was no contract between him and the plaintiff, and that though, as a public man and a member of Parliament, he had encouraged a project which it was supposed would be of public benefit, he was not himself one of those embarked in the speculation, had never taken or been allotted any shares, and had merely given the provisional committee his assistance and advice. It was alleged that at all events the plaintiff had resigned his office of engineer in September, when appointed to the Royal commission; and that, even supposing he had executed all the work, the charge of 40*l.* per mile was excessive. Considerable payments had been made to Mr. Nimmo.

The case occupied the whole day, and at nearly 8 o'clock the Court adjourned, postponing his Lordship's summing up until the following day, when his Lordship having gone through the facts of the case,

The Jury retired for a considerable time, and brought in a verdict for the plaintiff—Damages 1,980*l.*, being the balance due up to September 21, when they were of opinion he ceased to be engineer to the company.

Exportation of Machinery.—The select committee of the House of Commons, lately appointed to inquire into the operation of the existing laws affecting the exportation of machinery, have just published their second report to the House. This report is much too long to allow of any detailed reference to it, but we subjoin the final recommendation of the committee on the subject, which is to the following effect, viz.:—"That, considering that machinery is the only product of British industry upon the export of which restraints are placed, the committee recommend that the law prohibiting the export of machinery should be repealed, and the trade of machine making be placed upon the same footing as other departments of British industry."

STIRLING'S AIR ENGINE.

Messrs. Stirling have constructed an air-engine, now working at the Dundee Foundry, which fully realizes the expectations of the inventors; its superiority over the steam engine consists in an immense saving of fuel, and in its capability of being contained in a very small space. For the purposes of navigation these properties are invaluable. We subjoin a description of the air-engine, furnished us by a friend well acquainted with mechanics.

The air-engine now working at the Dundee Foundry, for which a patent was lately taken out, is the joint invention of the Reverend Dr. Stirling, of Galston, and of his brother, Mr. Stirling, engineer, Dundee.

The principle of the invention consists in alternately heating and cooling two bodies of air confined in two separate vessels, which are arranged so, that, by the stroke of two plungers worked by the engine, while the whole of the air contained in one of the vessels is at the lower end immediately over the furnace, and is consequently quite hot; the whole of the air contained in the other vessel is at that time disposed at the upper end, which is cut off from any communication with the furnace, and is therefore comparatively cold.

The expansion caused by the heat renders the air in the one vessel much more elastic than that in the other; and the two ends of the working cylinder, which is fitted with a piston similar to that of a steam-engine, being respectively connected with the two air-vessels; a preponderating pressure is produced on one side of the piston, and it is thereby pushed to the opposite end of the cylinder. By the alternate action of the plungers in the two air-vessels, this end of the cylinder then comes in its turn to be subjected to the pressure, and the piston is thereby pushed back again to its former position, and so it continues a reciprocating motion, and is applied to turn a crank in the same way that a steam engine does.

It has been satisfactorily shown that this engine may be worked with very great economy of fuel as compared with a steam engine; and the principal means of producing the saving is this; that, of the heat which is communicated to the air from the furnaces, only a very small portion is entirely thrown away when the air comes again to be cooled; for, by making the air, in its way from the hot to the cold end of the air-vessel, to pass through a chamber divided into a number of small apertures or passages, the great extent of surface with which it is thereby brought in contact, extracts in the first place, but only temporarily, the greater part of the heat from the air; and afterwards restores it to the air on its passage back again from the cold to the hot end of the vessel. The process of cooling is finally completed by making the air to pass through between a number of tubes in which there is a current of cold water, and thus far the heat cannot be made available again, but the portion which is abstracted in this way is very small.

As a sufficient expansive power could not be attained from using air of the common density of the atmosphere; without either making the diameter of the cylinder, and all the other parts of the engine inordinately large, or subjecting the air to greater alternations of heat and cold than would be convenient; the air is used pretty highly compressed, and a much greater power is thereby obtained upon a given area of the piston.

It is necessary therefore to employ a small air-pump to keep up the air to the requisite density: but very little power is expended on this; for, as the same body of air is used over and over again, all that is required of the air-pump, after the engine has been once charged, is to supply any loss that may arise from leakage; and this is found to be very trifling.

The machine has been working occasionally for about six months, and it has been proved, to the satisfaction of the inventors, to be capable of performing advantageously the amount of work which they had reckoned on, from their calculations, and from former experiments made on a working model of about two horses' power. It has now, for upwards of a month, been doing work in driving all the machinery employed at the extensive engineering works of the Dundee Foundry, which a steam engine of approved construction had hitherto been employed to do; and it has been ascertained that the expenditure of fuel is, *ceteris paribus*, only about one-fifth part of what was required for the steam engine; but, as considerable improvements are contemplated in some of the details, it is confidently expected that a much greater saving of fuel eventually will be effected.

The whole machine, including its furnaces and heating apparatus, stands in about the same space that a steam engine of equal power would occupy without its furnaces and boiler; and, taking into account this saving of space, along with the vast saving of fuel, the invention must necessarily be of immense importance for all ordinary purposes requiring motive power; and, as an instance, it would reduce the expense of the power employed in driving machinery in Dundee alone by at least 25,000*l.* or 30,000*l.* a year; but, viewed in reference to the purposes of navigation, the application of this invention must lead to results still more extraordinary, and will render a voyage to India round the Cape, by machinery, a matter of perfectly easy accomplishment.—*Dundee Advertiser.*

Herculaneum.—It is stated that the Neapolitan government have resolved upon undertaking some new excavations at Herculaneum and its neighbourhood, and it is added that they will be on an extensive scale. Negotiations have commenced already with this view for the purchase of various estates on the spot; and so soon as these purchases have been completed the works will be commenced. A commission of antiquaries and architects is to be appointed by the Minister of the Interior and the Royal Academy of Sciences to preside over the operations of the workmen; and no doubt discoveries will be made to add largely to the present knowledge of this interesting ruined city, and the manners and customs of its former inhabitants.

THE ZINKING PROCESS.

We derive from the *Revue Generale de l'Architecture* the materials for the following notes on the process of zinking iron, as described by the Baron Menu de Mesnil, in the Report of the Committee of Inquiry to the Minister of Marine in France. On the importance of preserving iron from oxydation it is unnecessary to make any remark, we may just observe that the only effective modes hitherto used have been tinning and glazing. In 1742 M. Maloin presented to the Royal Academy of Sciences a memoir on the analogy which he had observed between iron and tin, and points out a mode of zinking iron similar to the modern one. Whether the price of zinc was then too high or other difficulties stood in the way, it was not until 1836, that the process of zinking was made effective by M. Sorel, who took out a patent for it under the name of Galvanization of Iron. On the 28th September 1838, a committee was named by the Minister of Marine to make experiments in the dockyard at Brest on zinking iron, by them a first report was made recommending experiments to be made on a larger scale, which latter commenced on the 14th of May 1840, and it was on the 30th April of the present year that they made their report.

The process consists simply in dipping an iron article, previously cleaned with acid, for 3 or 4 minutes into zinc infusion, then taking it out progressively, shaking it in the air to get rid of the excess of zinc, and at last plunging it suddenly in cold water; after which it only requires to be rubbed over with fine sand and dried. What is called Galvanization is therefore nothing more than a process similar to tinning; but while iron is rendered more oxydable by contact with tin, and oxidizes rapidly, if by any mistake in the preparation the iron is left uncovered in any point; in zinking, on the contrary, a true alloy of zinc is formed on the surface of the iron, and the parts accidentally left unzinked alone rust, and the evil is soon stopped. This latter fact is enough to prove that the iron is not protected by any Galvanic effect as is the opinion generally received. Thus in the operations preparatory to zinking, such as cleaning by acid, &c., great care is taken to free the surface of the iron by scraping from it all matters which would resist the action of the acid, and prevent zinc from attaching to the iron all over.

The cleaning with acid is an operation which requires much care, for while it is indispensable that the iron subjected to the acid should be wholly free from rust, care must also be had that the iron be not too strongly acted upon by the acid, but be taken out at the proper moment. Very weak acids only are used for the cleaning as a mixture of nine parts of sulphuric acid with 100 of water. In France the refuse acid used in purifying vegetable oils is also employed; after a certain time the acid can no longer be used, as it is almost wholly turned into sulphate of iron, a salt which may be readily extracted, and which would bring more than the worth of the acid used. The time during which the iron is kept in the acid varies according to the degree of rust from 12 to 24 hours.

The pieces after coming out of the acid bath are cleaned and passed rapidly into hydrochloric acid of 15°, and then put in a stove to be quite dried. It is in this state of absolute dryness that they may be plunged into the zinc infusion. At the time of immersion the object is powdered over with sal-ammoniac, a great part of which volatilizes, and then decomposes, and the remainder, the acting portion, cleanses the object a third time, and makes the zinking certain and perfect. The use of this salt, on account of its value and the large quantity used, forms a great part of the cost of zinking. The zinc bath soon becomes covered with a black fluid matter, without adherence to the surface of the bath, on which it forms a continuous layer. The workmen consider it as advantageous to the zinking, and therefore take it out of the bath after the day's work, and put it in again the next morning, when they go back to work. During the night the zinc it kept in fusion, and the surface exposed to the air, is tarnished and oxydized, and it may be therefore allowed that the black matter acts so as to dissolve the oxide formed, and thus to restore the surface of the zinc to the purity requisite for zincing properly. An analysis of this black matter, made at Brest by M. Langonné, First Class Naval Apothecary and Member of the Committee, shows it to be composed of a great quantity of chlorure of zinc, a small portion of chlorure of iron, and an insoluble compound of ammoniac and zinc. As we know therefore that chlorure of zinc and ammoniac are good detersives, it is not surprising that the black matter, having an analogous composition, should be equally efficacious. The time that objects remain in the zinc bath depends on the dimension, if they are thin, they must be only rapidly passed through, if massive they must be left some minutes. In general it is enough to take the objects out as soon as they leave off giving out smoke or rather steam.

The immersion of the zinked object, still quite hot, in cold water, is for the purpose of preventing the formation of oxide of zinc, which tarnishes the surface, but this operation gives the iron a kind of tempering, which added to the effect of a layer of alloy covering the surface, renders it more brittle. Sheet iron in particular, on account of its thinness, is subject to this inconvenience, and can no longer be bent with ease. An improvement has however been recently made, which avoids the dipping, the slight layer of oxide of zinc which is formed on the surface, and which does not stick, is easily got rid off by rubbing after the object has been cooled in sawdust and sand.

When objects have just been zinked, they have a metallic lustre, which they will keep for a long time, when free from damp, but when left in the air they by little and little tarnish, become covered with a whitish efflorescence, which increases, acquires consistency, sticks to the metal, and soon forms a continuous and solid layer, which preserves the surface from ulterior alteration. This transformation is slow in taking effect, and appears to be complete only after 15 or 18 months' exposure to the air. Even the weakest acids and the alkalis attack and dissolve the zinc with the greatest facility and bare the iron. Heated red for several minutes the layer of zinc in excess soon peels off, but the iron is not yet bared, as the alloy of zinc and iron, more adherent, harder, and less fusible, long repel the action of heat.

The thickness of the zinc layer is very small; on cannon balls it was only 16 hundredths of a millimeter, on sheet iron it was from 7 to 12 thousandths of a millimeter, 9 thousandths is the mean. The thickness has little effect on the windage of cannon balls, but the committee suggest that zinking might be employed to increase the diameter of deficient balls. The committee farther suggest that experiments should be made to zinc old iron objects in order to preserve them. The thickness of the layer of zinc, although so very small, is amply sufficient, when we consider that an alloy is formed with the iron, which extends its protective influence deeper into the metal.

The influence of the air or water is very little on the zinked iron, if entirely exposed, but if subjected to the action of water and air alternately, they are more affected. Zinked apparatus produces no injurious effect upon drinkable water.

As to the various articles on which they experimented the committee report that the zinking appears very effective for roofs and cisterns. Zinked nails and bolts are recommended for shipping, but the committee are not yet prepared to recommend them to supersede copper. These nails are recommended for the decks of ships, as the ordinary nails soon produce a black spot on the surface of the wood, which penetrates and affects the fibres, gallate of iron being produced. Zinked nails are strongly urged as substitutes for iron in securing slates on roofs, as the iron nails soon rust, particularly near the sea, and in high winds are the chief cause of the slates falling. The zinked gutters the Committee consider will supersede tin. For the flues of stoves the zinked iron is recommended, and zinked wire also meets with their approbation. They had not made sufficient experiments as to chains, but they reported that those which they had tried, when put to the hydraulic test, supported it well. For locks and bolts in lighthouses and sea buildings, zinking is exclusively advocated. An advantage which zinc possesses for ear-rings for sails is that it does not rust the sails, which is apt to rot them.

The Committee conclude by making several recommendations. They report that zinking of wrought and cast iron can easily be practised in all ordinary circumstances of the use of that metal, that zinking shows every symptom of durability, and that it is of the greatest advantage to the navy. They consequently recommend a contract to be made with the patentee for the use of zinc in the arsenals of France, being convinced of its efficacy.

S. L. AND CANDIDUS.

The question at issue between S. L. and myself seems as it were about to be protracted as interminably as a Chancery suit. However we now seem to understand each other somewhat more clearly than at first:—at least there is one point on which he expresses himself decidedly, and on which I can cordially agree with him; since so far from attempting to defend, he unscrupulously reprobates that sickly soidisant *Greekism*, and pseudo-classical style, which during the last thirty years have given us so many "insipid abortions," where opportunities—now, alas! not to be recovered—presented themselves for achieving noble and original works.

Most certainly S. L. is not mistaken, when he imagines I will admit that Grecian and Roman architecture affords resources not yet worked out, ideas so capable of being yet further extended, that they may be said to be as yet only very partially developed, whereas they have only been studied and cramped in the mechanical productions of the school. My chief surprise is that he should for a moment doubt or affect to doubt my sentiments on that head, when I have more than once plainly stated—though perhaps in the very same terms I now use —that I am not an admirer of any one style in particular, however excellent it may be, to the exclusion of all others. My architectural creed is of a more liberal and comprehensive kind: it is free from those narrow sectarian prejudices that blind some to all beauty—all merit that does not come under the standard of their favourite style. So very far am I from being one of those who can not only tolerate, but admire even inferior productions, provided they do but belong—if only nominally—to what they consider the only legitimate mode, that as far as æsthetic value is concerned, I hold the manner in which a style is treated to be even of more importance than the question of style itself. So long as the work itself manifests artistic spirit, feeling and power, the particular language of the art, it happens to be composed in, is comparatively of little or no moment, however important it may be from other considerations attending any given case;—so far at least adopting Pope's doctrine that

"Whate'er is best administered is best."

By no means, was it my intention in what I first said to uphold the Gothic in preference to all other styles, nor did I conceive that it would be so construed by any one. And having thus cleared up S. L.'s misconceptions—or at least his doubts, I may now leave him to call Welby Pugin to account, as being a far greater offender—not only a staunch advocate for Gothic, but so exceedingly intolerant withal, that he would, were it in his power, exclude and uproot every thing else. Yet, should he have read the Professor's "True Principles," S. L. will probably not care to measure his strength with so redoubtable a champion. In case they should ever so encounter each other in argument, they may probably be so well matched that each will make a convert, —as such things have happened before now, and that S. L. will be converted to Puginism, while Pugin goes over to "Paganism."

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

INSTITUTION OF CIVIL ENGINEERS.

April 6.—The PRESIDENT in the Chair.

Experiments on the strength of Iron Girders. By Thomas Cubitt, Assoc. Inst. C. E.

This communication gives in a tabular form the results of experiments upon upwards of 60 pairs of cast iron girders, varying in length between 7 ft. 6 in. and 27 feet, with corresponding depths, and of all the forms usually adopted for beams for buildings. They were proved in pairs by a hydraulic press placed between them, the ends being retained by wrought iron ties. The deflexion was noted at each increase of pressure, and in many instances the beams were fractured.

Sketches of the girders, and of the apparatus used for proving them, accompanied the paper; from them five drawings have been made at the Institution to facilitate a reference to the information contained in the communication.

Description of an improved Level and Stand. By G. Townsend.

This improvement being intended to procure a firmer basis and greater facility of adjustment than by the ordinary level, the author has adopted the principle of the triangular plate, with three levelling screws. In the ordinary instrument, with two pairs of screws, it has been found that the antagonist screws, besides being apt to wear unequally, and to indent the lower plate, are sometimes bent, and thus cause an unequal action upon the upper plate. To obviate these defects, the screws in the tripod level are made to work into inverted cones, which are fixed in the three grooved arms of the stand head; the weight is more equally distributed, and the telescope more speedily brought to a level.

The telescope is fixed to the levelling plate by an upright limb, and to this is added a small longitudinal cross level, as in Gravatt's instrument. In the improved stand, each of the legs is attached to two arms of the lower tripod plate, by which means a firmer basis is obtained. The usual locking plate, to secure the levelling screws, is also attached to this instrument, and kept in place by a spring catch; there is also a metal ring fixed on the upright limb, above the arms, and which falls into three spring catches in the table plate, by which any derangement from accidental violence, or in removal from one station to another, is effectually prevented.

A small circular spirit level is fixed in the stand in order to adjust it before the instrument be placed on it, by which means the labour of adjustment is considerably abridged.

April 20.—The PRESIDENT in the Chair.

Experiments for determining the position of the Neutral Axis of rectangular beams of Cast and Wrought Iron and Wood, and also for ascertaining the relative amount of compression and extension at their upper and under surfaces, when subjected to transverse strain. By Joseph Colthurst.

These experiments were undertaken in consequence of the difference of opinion which has long existed respecting the position of the neutral axis of extension and compression of iron and wood.

First experiment.—Two series of experiments were made to determine this point by cutting through the centre of each of a set of eight girders, each 6 ft. 6 in. long, 5 in. deep, and half inch thick, the first to the depth of half an inch, the second to the depth of 1 inch, and so on, to the eighth girder, in which only 1 inch of metal remained unsevered. The spaces cut out were then filled with carefully fitted wrought iron keys, and the girders were broken by the application of weights, in the expectation that these weights would be some indication of the neutral point of each girder. The results were, however, so irregular, that no satisfactory deductions could be drawn from them.

Second experiment.—The next attempt was made in the manner suggested by the late Mr. Tredgold, by drawing two fine lines, 2¾ inches apart, on a polished surface at right angles to a girder, in the middle of its length; it was then subjected to strain, and dimensions were sought to be taken to determine where their divergence and convergence commenced, but the differences were too small to be susceptible of accurate determination, otherwise than by a fine micrometrical operation, which at the time the author had not an opportunity of applying. The following plan was therefore adopted.

Third experiment.—In the side of a cast-iron girder, 6 ft. 6 in. long, 7 in. deep, and 1 inch thick, a recess was planed at the centre, 3 in. wide by ½ in. deep. This was filed up very true, and fourteen small bars of wrought iron, with conical ends, were placed in it at regular distances of ½ an inch apart. These bars were of such lengths as to hold sufficiently tight to carry their own weight, and yet that the slightest touch should detach them. The girder was then subjected to strain. The supports were 6 feet apart; with a strain equal to 100 lb. the lower bar fell out; as it was increased, they continued to drop, and with 1500 lb. all those below the centre had fallen. The strain was then increased to 7000 lb., but no more bars fell. The centre bar remained exactly as when put in; all those above the centre became firmly fixed, and were evidently under considerable compressive force. The strain was then gradually taken off, and all the bars above the centre fell out, their ends having become compressed by the sides of the recess pressing on them; they were of course too short when the girder resumed its former condition, and the recess its previous width. These experiments were repeated several times, with pieces of fine wire and dry lance-wood charred at the ends.

The result in every case showed that the *neutral axis* of extension and compression was certainly situated within $\frac{1}{16}$ of an inch of the centre.

Another experiment was still more decisive. A girder 9 ft. 6 in. long, 8 in. deep, 1 in. thick, was cast with two brackets or projections on the side, each 9 in. on either side of the centre. A brass tube bar, with circular ends and a sliding adjustment, was fixed between the brackets, which had been filed true. The clear bearing was 7 ft. 6 in.; a strain of 50 lb. was sufficient to cause this bar to drop out; and with 250 lb. the whole effect of the previous experiment was produced. The tube, when placed loosely, 1 inch above the centre, was held fast by a strain of 1000 lb.

Wrought Iron.—Similar experiments were then made on wrought iron, with precisely the same results, showing that the neutral axis, if not actually situated at the centre, was nearly identical with it.

Wood.—A similar series of experiments, made upon wood beams, gave exactly the same results as regarded the position of the neutral axis.

From all the foregoing experiments, the author concludes that the neutral axis of extension and compression in rectangular beams of cast and wrought iron and wood, is situated at the centre of their depth, when those beams are subjected to transverse strains.

Extension and compression. Cast Iron.—Experiments were also instituted to ascertain the amount of extension and compression of cast and wrought iron and wood.

Upon a bar of cast iron, 3 inches square, and 9 feet long, two strips of thin hoop iron were attached, the one on the upper, and the other on the lower side, each strip being fastened to the bar at one end only, while the other end was left free; any change which occurred in the length of the surface to which it was applied was clearly indicated. The differences were recorded by very fine lines on a polished surface. The strips were 7 ft. 6 in. long, and were bound to the whole length of the beam by bands of fine wire, wound round and enclosing them at every 9 inches; the beam was then subjected to strain, and the following results were obtained:—

Weight. lb.	Deflection. inches.	Compression. inches.	Extension. inches.
1000	0·22	..	..
2000	0·45	0·044	·048
3000	0·65	0·06	0·06
4000	0·87	0·08	0·08
5000	1·20	0·11	0·12
6000	1·50	0·13	0·14
6340 the beam broke; good iron, showing a good clear fracture.			

It will be perceived, that until rather more than two-thirds of the breaking weight was put on, the amounts of extension and compression did not vary sibly differ, but between that point and the breaking weight, extension yielded in a higher ratio than compression.

Wrought Iron.—Similar experiments were next made on bars of wrought iron, 2¼ in. square; the supports were 13 ft. 6 in. apart, and the strips of hoop iron were 12 feet long.

Weight. lbs.	Deflection. inches.	Compression. inches.	Extension. inches.	Elasticity. impaired.
500	0·55	0·03	0·03	..
1000	1·35	0·06	0·06	..
1250	1·45	0·07	0·07	0·15
1500	1·65	0·08	0·08	..
1800	2·20	0·09	0·09	..
2000	2·70	0·11	0·11	0·65
2280	4·15	0·18	0·19	2·05

With this weight the beam was permanently bent, and its elasticity nearly destroyed.

These experiments showed that, differing from cast iron, the amounts of extension and compression in wrought iron continue to be equal up to the complete destruction of the elasticity of the beam.

Fir battens.—The amounts of extension and compression in rectangular beams of fir timber, when subjected to transverse strain, were next determined; the manner of proceeding was precisely the same as in the preceding experiments.

A batten, 4 in. by 3 in., with the supports 8 ft. 2 in. apart, and with strips 7 ft. 6 in. long, when subjected to transverse strain, gave these results :—

Weight. lb.	Deflection. inches.	Compression. inches.	Extension. inches.
500	1·10	0·12	0·12
1000	2·30	0·24	0·24

Results.—From these experiments on the amount of extension and compression of cast iron, measured at the under and upper surfaces of rectangular beams, subjected to transverse strain, the author assumes, that within limits which considerably exceed those of elasticity, and equal to at least two-thirds of the breaking weight, there is no sensible difference between the amounts of compression and extension, and that as the breaking point is approached, extension yields in a higher ratio than compression, and gives way first.

It would appear certain that up to the point when the elasticity of wrought iron is completely destroyed, and the beam is bent, the amounts of compression and extension continue exactly equal, and it is therefore probable that this equality would continue to the last.

It is clear that the amounts of extension and compression up to three-fourths of the breaking weight do not sensibly differ in fir battens, but that as the ultimate strength of the beam is approached, compression yields in a much higher ratio than extension, and may be actually seen to give way first.

He states also, that the amounts of extension and compression are in direct proportion to the strain, within the limits of elasticity, and that even after those limits are greatly exceeded, and up to three-fourths of the strength of a beam, they do not sensibly differ.

The apparatus with which these experiments were made was exhibited, and presented by the author to the Institution.

Mr. Donkin eulogised the novel and ingenious manner in which Mr. Colthurst had conducted the experiments, which he considered to be highly satisfactory. They not only determined the position of the neutral axis of the beams experimented upon, but showed also the relative amounts of compression and extension, so as to demonstrate that the elasticity of a body was the same in compression as in extension. These experiments also confirmed the correctness of Tredgold's opinion as to the pernicious effects of attempting to produce peculiar forms in beams by cambering and inserting wedges into their upper sides.

Mr. Vignoles reminded the meeting of the discussions which had taken place relative to the position of the neutral axis in the railway bars, which had the upper and under tables similar; it was contended that the neutral axis was situated close beneath the upper lip, or table of the rail, whereas, if Mr. Colthurst's mode of experimenting had been adopted, a different and more correct result would have been arrived at.

Mr. Cubitt accorded great merit to Mr. Colthurst for the experiments, which had determined the question as regarded rectangular beams. It appeared that no attempt had been made to use the same mode of proceeding with beams of irregular figures; in them, therefore, it might be concluded, that the neutral axis would be found in the centre of gravity of the section of the beam.

Mr. J. Horne remarked, that these experiments perfectly accorded with those which he laid before the Institution in 1837. His object had been to show that the neutral axis was always in the centre of gravity of the section, as well as to determine the figure which should resist the greatest amount of pressure with a given quantity of materials; the strongest form was shown to be a prism, placed with the base upwards, and the same figure reversed was the weakest; the strength of the former figure exceeded that of the latter by at least one-third.

April 27.—The PRESIDENT in the Chair.

Memoir of the Montrose Suspension Bridge. By J. M. Rendel, M. Inst. C.E.

Previous to the year 1792, the passage of the River Esk at Montrose was effected by common ferry boats; at that period an act of parliament was obtained for the construction of a wooden bridge, with numerous arches, or rather openings formed by beams, supported upon piles, with stone abutments at either end; the action of the tide undermining the piles, and the usual progress of decay causing great expense for repairs, it was decided in the year 1825, to erect a suspension bridge, the iron work of which was contracted for by Captain Samuel Brown, R.N., for the sum of £9,430, and the masonry of the towers for £9,080. The total cost being £18,510, exclusive of the land arches and approaches; those of the old bridge being preserved for the new one.

The dimensions of the new bridge were—

	Feet.
Distance from centre to centre of the towers . . .	432
Deflection of the chain or versed sine of the catenary .	42
Length of the suspended roadway	412
Width of ditto	26
Height of ditto above low water	21
Ditto of the towers above ditto	68
Base of the towers at the level of the roadway . .	40 by 20
Archways through the towers . .	16 wide, 24 high

The towers were built of red sandstone ashlar, raised on a base of the same material, carried upon piles.

Construction.—There were two main chains on each side, arranged above each other in parallel curves, 12 inches apart. Each chain was composed of four bars of iron, 5 inches wide by 1 inch thick, and 10 feet long, united by short plates, and strong wrought iron pins. The roadway was suspended to these chains by perpendicular rods, 1¼ inch in diameter, attached at intervals of 5 feet, alternately to the upper and lower lines of main chains, at the joints, which were arranged so that those of the upper chain should be over the long bars of the lower one; at the lower end of each suspending rod was a stirrup, which received and carried the cast-iron bearers for supporting the roadway.

Upon these bearers was laid and rivetted longitudinally a flooring of fir planks, 3 inches thick, and well caulked; upon this a sheathing of fir, 1½ in. thick, was placed transversely, and spiked to the lower planks; over all was spread a coating of about 1 inch thick of fine gravel and sand, cemented with coal tar.

The suspending rods were without joints. The main chains rested upon detached cast iron saddles, built into the masonry of the towers, and passing down at either extremity, were secured behind cast iron plates in masses of masonry, 10 feet under ground.

The construction was commenced in September, 1828, and was finished in December, 1829, a period of only sixteen months.

Accident to the Bridge.—On the 19th of March, 1830, about 700 persons assembled on the bridge to witness a boat race, when one of the main chains gave way, and caused considerable loss of life. The injury was speedily repaired, but a careful survey of the structure was ordered, and it was discovered that the intermediate or long links of the chains bore so unequally upon the saddles as to be bent and partially fractured. Mr. Telford, who was consulted on the subject, proposed the addition of two other main chains placed above the original ones, and having the same curve, so as to increase the sectional area 40 inches—thus giving six chains of 20 inches area each, instead of four chains, as originally constructed.

Mr. Telford's decease occurring at that period, the author was instructed to report upon the state of the bridge, and advise such alterations as he judged to be necessary.

After a minute personal inspection he concurred in Mr. Telford's idea of the necessity of increasing the strength of the bridge, but instead of augmenting the number of the chains, he advised the addition of two bars in width to each of those existing, by which means the required strength might be gained. He was led to this by an opinion that, in all cases, it is desirable to have as few chains as possible.

It appeared that there had been but little precision in the workmanship of the chains; for on releasing them they immediately became twisted; thus showing that all the links had not a true bearing. On taking them apart, many of the traversing pins were found to be bent, and some of them were cut into, evidently by the friction of the links. This was to be rectified, and new saddles of a different principle and stronger form were recommended: also, that those parts of the chains which rested in the saddles should be entirely composed of short plates. Additions to the masses of masonry holding the chains were likewise deemed advisable.

Between the years 1835 and 1838, all the principal works, with many minor improvements, were executed.

In the author's report on the state of the bridge, he noticed what he deemed defects in the construction of the roadway, but as there was no positive symptom of failure, it was allowed to remain. He conceived, that in the anxiety to obtain a light roadway, mathematicians and even practical engineers had overlooked the fact, that when lightness induced flexibility, and consequently motion, the force of momentum was brought into action, and its amount defied calculation.

On the 11th of October, 1838, the roadway of the bridge was destroyed by a hurricane, the effect of which upon this structure is the subject of a paper by Colonel Pasley, published in part 3, vol. 3, of the Transactions of the Institution C. E. To that account the author refers for the principal details, only adding, that on inspecting the bridge, he found the chains, the saddles, and the fastenings or moorings, quite sound; the principal portion of the roadway had been completely carried away, and the remainder much injured. He then gives some account of the undulatory motion observed during the storm. This motion was greatest at about midway between the towers and the centre of the roadway; but the waves of the platform did not coincide with those of the chains, either in magnitude or in order; no oscillatory motion was perceived either in the roadway or in the chains, although particular attention was directed to them.

It appears that the centre of the platform fell in a mass. This the author attributes to the failure of the suspension rods, which, having no joints, were twisted off close to the floor by the undulatory motion. A similar occurrence at the Menai Bridge* induced Mr. Provis to adopt the joints in the suspension rods, which the author had previously introduced at the Montrose Bridge.

The author had long been convinced of the importance of giving to the roadways of suspension bridges the greatest possible amount of stiffness, in such a manner as to distribute the load or the effect of any violent action over a considerable extent.

The platforms of large bridges, in exposed situations, are acted upon in so many different ways by the wind, that he had an objection to the use of stays or braces to counteract movements which ought rather to be resisted by the form of the structure.

Holding such opinions, he determined to adopt a framing which, although connectedly rigid in every direction, should nevertheless be simple, composed of few parts, capable of being easily renewed; should distribute its weight uniformly over the chains, not be subject to change from variation of temperature, and not augment the usual weight of suspended platforms.

The details of the alterations, and general repair of the bridge, are then given; a few may be mentioned.

An entirely new set of stronger suspending rods was introduced; they were 1½ of an inch in diameter down to the flexible joint at the level of the platform; below that point the diameter was increased to 1¾ of an inch, and a strong thread was cut on to the lower end, so as to adjust them to the requisite lengths.

In the place of the cast iron bearers cross beams were substituted, composed of two Memel planks, 13 inches deep, 3½ inches thick, bolted together, and trussed with a round bar 1¼ inch diameter; every sixth beam had a deep trussed frame on the under side, so as to give great stiffness. Above and beneath the cross beams, on each side of the carriage way, were bolted two sets of longitudinal timbers, four in each set; they were further united by cast iron boxes, at intervals of 10 feet; and the ends were secured to beams of English oak, built into the masonry of the towers. A curb of Memel timber, 11 inches by 6 inches, was attached to the ends of the cross bearers, and extended the whole length of the platform.

The planking of the footways was composed of narrow battens, 2 inches thick, laid transversely from the inner longitudinal beam to the outer curb piece, with an inclination or drip of 1½ inch in 5 feet.

The carriage way was formed of four thicknesses of Memel plank; the two lower layers, each 2 inches thick, were placed diagonally with the transverse beams, crossing each other so as to form a reticulated floor, abutted against the longitudinal beams; they were firmly spiked to the beams, and to each other, at all the intersections, and upon them was laid and spiked a longitudinal layer of Memel planking, 2 inches thick. Over the whole was fixed, transversely, a layer of slit battens, 1½ inch thick. Each layer was close jointed and caulked, and the upper one was laid in a mixture of pitch and tar. A composition of fine gravel and sand, cemented with boiled gas tar, was laid over the whole, to the thickness of 1 inch, forming the road track.

To add to the stiffness afforded by this construction, the author caused to be passed through the spaces between the pairs of longitudinal beams, a series of diagonal truss pieces of Memel timber, 6 inches square, with their ends stepped into the cast-iron boxes, which, at every 10 feet, grasp the beams. On the other ends of these diagonal truss pieces, cast iron boxes were fixed, which received the straining pieces, placed 3 ft. 6 in. above, and the same depth below, the roadway: an iron screw bolt, 1½ inch diameter, at every 10 feet, and a contrivance of wedges in the cast iron boxes, enabled any degree of tension to be given to the framing.

The roadway was thus stiffened by two of the strongest kinds of framing, in parallel lines, dividing the carriage way from the foot-paths; it was deemed preferable to disconnect them from the suspending rods, and, by bringing them nearer together, to avoid a twisting or unequal strain. The whole formed a compact mass of braced wood work, the diagonal planking giving the horizontal stiffness, and the two trussed frames insuring the vertical rigidity.

The weight of the new roadway was—

	Tons.	Cwt.
Wood work	130	19
Cast and wrought iron about ditto	36	6
Wrought iron in the suspending rods	20	14
Ditto in the fencing	8	18
Gravel concrete	30	0
Total	226	17

Or 47.5 lb. per square foot, superficial, for the entire roadway.

* Minutes of proceedings, pages 167, and 204.

The weight of the original roadway was—

	Tons.	Cwt.
Wood work	69	0
Cast iron about ditto	92	9
Wrought iron in the suspending rod	12	0
Gravel concrete	30	0
Total	203	9

Or 23 tons less than the new roadway.

Cost.—The platform described is 412 feet long, and 27 feet wide; it cost £4026 or about 7*s.* 3*d.* per superficial foot.

The works were completed in the summer of 1840; the bridge has borne without injury the gales of the last winter; and the stiffness of the platform has given confidence in its strength to all who have examined it.

Five elaborate drawings of the bridge, giving all the details of its construction on a large scale, accompanied this communication; they were presented by Mr. Page on his election as an Associate of the Institution.

Mr. Seaward agreed with Mr. Rendel in the advantage of reducing the number of suspension chains, and thus rendering the whole construction as simple as possible. The trussed framing, which appeared to be the main feature of this bridge, was particularly deserving of commendation, as it imparted a degree of stiffness to the platform which had not hitherto been attained in other cases, although it was demonstrated to be the best method of preventing the undulation which was so prejudicial to the suspension bridges.

Mr. Rendel had, on a previous occasion,* explained his view of the action of wind upon the platforms of suspension bridges, and of the necessity of a certain degree of stiffness in the construction; this he conceived would always be better attained by having a simple well-trussed framing to prevent undulation, than by the application of braces or stays to check either undulation or oscillation—the latter being in his opinion only the result of the former.

He would now only insist more forcibly upon those points. The roadway should be so stiff as to prevent as much as possible all tendency to motion because it added to the natural decay of every part of the structures; for instance, he found on taking down the chain of the Montrose Bridge, after seven or eight years' wear, that the pins of the links were cut some depth into; demonstrating how great had been the amount of motion among the links. In constructing suspension chains, after this experience, he should be inclined to abandon the circular form for the pins, and forge them of a long oval shape in their transverse section; making the apertures in the links by drilling two holes, and cutting out the metal between them with a machine this form of pin would allow sufficient play for the necessary curve of the chain, while the pin itself would be stronger, would weaken the link less than the large circular hole, and would be less expensive to manufacture He disapproved of all the complicated contrivances for allowing expansion of the main chains; he had found that plain saddles of proper form were quite sufficient to permit the expansion of the back chains, which was all that required attention.

Mr. Palmer mentioned, on the authority of Mr. Chapman, the destruction of a suspension bridge in America, caused by the sudden passing of a drove of cattle when frightened. This was peculiar, as it always had been considered that an irregular motion was innocuous, but that when any regular impulses were communicated, there was danger of fracture of the bars.

Mr. Vignoles eulogized this excellent communication for the practical conclusions which it contained. Mr. Rendel had materially assisted in affording facility of communication by the introduction of the floating bridges, in communication with railways, and it was not difficult to foresee that, by carrying out the system of adapting well-trussed framings to the platforms of suspension bridges, sufficient rigidity would be attained for locomotive engines and carriages on railways, to traverse rivers or ravines by means of these bridges instead of by costly viaducts or heavy embankments.

Mr. Rendel saw no difficulty in giving any required amount of rigidity to the platforms; it was only necessary to increase the strength of the framing to enable the roadway to bear with perfect safety the passage of an engine and a train of carriages.

The President directed the attention of the members to what he considered the most valuable part of this interesting communication—the detection of the errors in the original construction of the bridge. This was the most useful class of papers which members could present to the Institution, and they were particularly valuable when they were illustrated by such complete drawings as those now communicated by Mr. Page on his election. He hoped this example would be extensively followed. He mentioned that an attempt had been made to carry a railway across the Tees by a suspension bridge, but it had been abandoned.

Mr. Rendel understood that the weight of the trains had so stretched the chains, or rather forced the moorings of the back chains of the bridge over the Tees, that the platform sunk in the centre so as to prevent the passage of the carriages; piles had therefore been driven beneath each bearer of the roadway, and the chains now remained merely to show that it had formerly been a suspension bridge.

May 4.—The President in the Chair.

"*Supplementary Account of the Use of auxiliary Steam Power, on board the 'Earl of Hardwicke' and the 'Vernon' Indiamen.*" By Samuel Seaward, M. Inst. C.E.

* Minutes of Proceedings, page 205

The advantage of the employment of auxiliary steam power, on board large sailing ships, had been shown by the author in a former paper (p. 63); it was now further exemplified by the result of the recent voyages of the "Earl of Hardwicke" and the "Vernon."

Earl of Hardwicke.—This vessel, of 1000 tons burthen, with one engine of 30-horse power, effected the voyage from Portsmouth to Calcutta in 110 days, a much longer time than usual; but still with an advantage of 29 days over the "Scotia," a fine vessel of 800 tons, which sailed one week before the "Hardwicke," and arrived 22 days after her. During the voyage, the "Hardwicke" used her engine 364 hours, and was propelled by it 946 knots; an average of nearly three knots per hour: while in a calm, with the ship steady, she made five knots per hour. The total consumption of fuel was 90 tons.

The "Vernon," which sailed one month after the "Hardwicke," made her passage to Calcutta in 97 days; passed the "Scotia," and arrived seven days before her, gaining 42 days upon her during the voyage. The "Vernon's" consumption of fuel was also 90 tons, but the copy of her log not being arrived, the number of hours during which steam was used, could not be ascertained.

The "India" steam ship, of 800 tons burthen, with engines of 300 horse power, had not arrived at Calcutta, although she had been out 109 days, so that the "Vernon," with only auxiliary steam power, had already gained 12 days upon her.

The comparison between the advantages of these two vessels, in point of expense, is then fully entered into, and shows a saving of £3733 in favour of the "Vernon," on a single voyage, while she gained at least 12 days upon the "India," in point of time.

This communication is accompanied by a copy of the log of the "Earl of Hardwicke," and by letters from the captains of that ship and the "Vernon," speaking in the highest terms of the assistance of the steam power in certain parts of the voyage."

"*Description of an improved Levelling Staff, and a modification of the common Level.*" By Thomas Stevenson.

In enumerating the advantages of this improvement, the author passes in review the different levelling instruments in general use. He describes the self-reading staff as very useful, but ill adapted to the extreme accuracy generally necessary in the operation of levelling.—He considers the running level to be equally inadequate, from the difficulty of attaining a precise coincidence in the cross wires and the vane line.

On the authority of Mr. Simms, in his Treatise on Mathematical Instruments, he states that these evils are in some measure remedied by Mr. Gravatts' rod, but he still considers that instrument to be imperfect. He therefore caused a rod to be constructed by Mr. Adie, of Edinburgh, the vane of which is adjusted by tangent screws. The range of this staff is 12·7 feet, and the graduation so perfect as to be read by verniers to the $\frac{1}{1000}$th of a foot. On the right of the lower portion of the rod there is a screw, which, on being tightened, clamps the vane, and on the opposite side is the tangent screw for adjusting it. Supposing in practice that the level line strikes the lower half of the rod, the vane and screw are then easily moved by the hand to within $\frac{1}{4}$ inch of the point, and then, by means of the tangent screw, perfect correctness can be attained.

After having sent his communication to the Institution, the author learnt from the Secretary that adjusting screws had already been used in two other levelling staves by Captain Lloyd and by Mr. Bunt. He was not, however, aware of this circumstance, and he considers that these instruments being adapted only for scientific purposes, are hardly suitable for the ordinary use of the engineer.

Improved Level.—The author also introduced a ball and socket joint at the junction of the legs of the common level, retaining at the same time the parallel screw plates, and adding beneath a small sluggish spherical level. By these means the surveyor is enabled to station the instrument, regardless either of the inequalities of the ground, or of the inclination of the telescope to the horizon.

When in use the clamp of the ball and socket is released, and the head of the level moved until the bubble shall be in the middle of the circle; the socket screw is then clamped, and the telescope brought to the absolute level by means of the parallel screws. It becomes thus unnecessary to move the legs of the instrument when once fixed.

"*An improved mode of Paving Streets.*" By Edward Lomax.

In this communication the author proposes to remedy the danger and difficulty of stopping or turning horses during wet or frosty weather on wood pavement. His plan is, that a breadth of 2 feet 6 inches, near each side of the street, should be paved with stone, for the horses to travel upon, the carriage wheels still running upon wood; by which means all the advantages of that kind of pavement would be preserved, without risk to the horse. In very wide streets a centre track might also be paved with stone.

By this plan the labour of the horse would be greatly diminished, a considerable portion of his power being now lost, because the wood pavement is less favourable for the footing of the horse than for the motion of the wheels.

The author is therefore of opinion, that granite pavement for the horse to travel upon, and wood pavement for the wheel way, would form a road on which the horse would work with the least loss of power, and the greatest safety.

A model of the proposed improvement accompanied the paper.

"*Specimens of Sea-weed used for sea defences.*"

Mr. Macneill presented three specimens of the Sea-weed with which the Sea Embankments are formed in some parts of Holland.—He described one of the specimens in its natural state as resembling the weed which is collected by the peasantry on the western and north-western shores of Ireland, and used by them for bedding.—The second specimen was taken from near the bottom of the embankment at Niewe Diep, the entrance of the grand canal near the Helder. It was much compressed, but elastic.—The third specimen was less compressed; it was taken from the same embankment, above the range of the ordinary neap tides.

This embankment is of considerable width, and has very little slope towards the sea: the work appeared extremely compact and solid; he saw it when a heavy sea was running in, and each action of the waves against it caused a vibration throughout the whole mass—thus proving the elasticity of the material when consolidated, and corroborating the Hon. Mr. Stewart's description of the same effect upon the peat sod embankments, in a paper shortly to be laid before the Institution. Mr. Macneill spoke with confidence of the efficiency of the peat sod for sea defences, as he had used it with good effect, although at present only to a limited extent.

The attention of the Members of the Institution was especially directed to the sea embankments of Holland, as affording excellent study and ample materials for communications for the meetings.

On Lead Sheathing for Ships. By J. J. Wilkinson.

The commencement of this communication, which is the continuation of the paper on the "Wood sheathing of Ships," which was read March 23rd (page 318), examines in great detail the various uses to which metals were put in the earliest period of which any record exists, and then it traces the first application of lead to the protection of shipping.

There are very early instances of ships and vessels being covered with lead. In the 15th century, a boat, 30 feet in length, was found in the Mediterranean sunk in 12 fathoms water; it was built of cypress and larch. The deck was covered with paper and linen, and over all with plates of lead, fastened with gilt nails; this covering proved so impervious to moisture, that parts of the interior were perfectly dry. It is supposed to have lain there above 1400 years. A Roman ship was also found sunk in the Lake of Nemi. The hull was of larch; bitumen had been applied to the outside, over which was a coating of a reddish colour, and the whole covered with sheets of lead, fastened by gilt nails. The interior had a thick coating of cement made of iron and clay. The seams of the planks were caulked with tow and pitch.

Some of the ancient domes at Ephesus were sheathed with lead, and it appears that the column of Constantine at Constantinople was formerly covered with metal.

It is certain that lead mines were worked in Britain by the Romans; and long before the Conquest, plates of lead were used as coverings for ecclesiastical buildings. These coverings being designed to endure, were of very thick lead.

Water pipes.—In 1231, water was brought from Tyburn to London in pipes; but the material of the pipes has not been ascertained. In 1285, the great conduit in Cheapside was supplied with water conveyed through pipes from Paddington; these pipes are expressly stated to have been of lead. It has, however, been averred, that lead pipes for conveying water were first introduced by Robert Brook, in the reign of Henry the Eighth.

Sheet lead was used in Spain and Portugal for sheathing ships, and for covering the rudders, long before it was employed in England. It was used in Holland in 1666, and at Venice in 1710.—It is probable that we are indebted to Sebastian Cabot for its introduction into England; it is stated in his Memoirs that he first saw it used in 1514; he was then in the service of the king of Spain, which he entered in 1512, and was appointed pilot major; he afterwards returned to England, and in 1553 was named by Queen Mary, "Governor of the Mysterie and Company of Merchant Adventurers, for the discovery of Regions, Dominions, Islands, and Places, unknown."—Three vessels were fitted out for this purpose, under the command of Sir Hugh Willoughby, one of which was sheathed, or at least partly so, with thin plates of lead, then first mentioned as an "ingenious invention." This expedition was unfortunate—Sir Hugh Willoughby, with the crew of two of his ships, being frozen to death; one of the commanders, and his crew, alone escaped. This expedition was the origin of the trade to Russia, and of the Spitzbergen Whale Fishery.

In the reign of Elizabeth a patent was granted to one Humphrey, for melting lead, but was afterwards recalled, the plan not being new.

Milled lead.—It appears that, up to about 1670, cast sheet lead was used for sheathing; at that time milled lead was invented, and a patent for milling lead was granted to Sir Philip Howard and Francis Watson; by this process the inequalities, as well as the defects from air holes, in the former mode of manufacture, were remedied; the whole surface was rendered smooth and uniform, and the weight greatly reduced. This invention met with much opposition from the plumbers, who averred that it could not be durable; an offer was therefore made on the part of the Milled Lead Company, to keep in repair during 41 years all milled lead of the weight of 7 lb. per square foot, at the rate of five shillings annually per each hundred pounds worth in value.—One of the earliest vessels in the royal navy thus sheathed, was the Phœnix, a fourth-rate. This was done at the express command of Charles II. This vessel made two voyages to the Straits, apparently for the express purpose of testing the new invention, and on her return in 1675, was careened at Deptford, and personally inspected by the King. An order was then issued that his Majesty's ships should in future be sheathed only with lead, excepting by especial order from the Navy Board. It appears that about 20 ships of the royal navy were consequently sheathed with milled lead, and fastened with copper nails.—Even the royal protection could not save this invention from cavillers, so that, in 1677 and 1678, complaints were made by Sir John Narborough and Sir John Kempthorne, that the rudder irons of the Plymouth and the Dreadnought were so much eaten, as to render it unsafe for those vessels to proceed to sea; these complaints were repeated in 1682.—The patentees maintained, on the contrary, that the damage to the rudder irons could not possibly arise from their being covered with lead, as it had been the invariable practice for a great many years, to secure the iron work of ships, generally, by lead covering, and especially by capping the heads of their bolts, under water, with lead, seized to and nailed over them. Reports too in favour of the invention were made by Sir Phineas Pett, and by Mr. Betts, master builder, at Portsmouth, in which the latter stated, that lead had effectually prevented the vessels becoming what is technically termed "iron-sick," meaning that the bolt-holes became so widened by corrosion, that the bolts were loosened; he recommended, however, that the lead sheathing should be stripped every seven years, on account of the decay of the oakum in the joints; declaring, too, that it became less foul on the voyage than wood sheathing, and was much more easily cleaned. These different opinions led to the issue of an Order in Council in 1682, for the appointment of commissioners to examine and report upon the alleged injury to the iron work by milled lead covering; it is probable their report was unfavourable, as it is said that the use of lead covering, fastened with copper nails, was abandoned on account of the rapid corrosion of the rudder irons. A controversy appears to have arisen on this subject, the merits of which it would be difficult to ascertain after such a lapse of years. Government, however, subsequently determined to make another trial of the value of lead covering; accordingly, the Marlborough was so sheathed, and laid up in ordinary, at Sheerness. A few years after, she was docked, at Chatham, in 1770, when it was found that the lead sheathing was covered with weeds, and the iron fastenings very much decayed; the lead was in consequence removed, and a wood sheathing substituted.

Mixture of metals.—Several patents were afterwards obtained for different mixtures of metal for this purpose, none of which seem to have succeeded, being all subject to the same inconveniences as the simple metal; among which was the influence of the sun in the torrid zone, which was said to reduce the lead, in the course of five or six years, to a calx.—Among these patents, for mixed metals for sheathing, is mentioned that of Mr. Bulteel, in 1693; it was found to have all the inconveniences of lead. Mr. Donithorne, in 1780, obtained a patent for sheathing, of a mixture of 112 parts of tin to 10 parts of zinc; this was also as objectionable as lead.—Slade's patent for sheathing with copper laid upon lead, and the patents of Wetterstedt, and of Muntz, for mixed metals, are examined; and the author promises a continuation of the subject, with the history of copper sheathing.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

ELEVENTH MEETING, 1841.

(From the reports of the Athenæum.)

"*On Truscott's plan for Reefing Paddle Wheels.*"

Mr. Chatfield described, by reference to a model, an improved paddle-wheel, the principal feature of which was a new application of the principle of feathering and reefing. Each paddle or float is attached to an axis passing through its centre, with a crank at the extremity of the axis, and the feathering is effected by the motion of a roller attached to this crank, and moving in a groove eccentric to the wheels. The radii of the paddle wheel are connected at their extremities by a chain instead of a rigid rim, and the reefing is effected by drawing the radii together, like the folding of a fan, by means of a peculiar arrangement of the clutch box at the centre of the wheel.

"*On a Plan of Disengaging and Reconnecting the Paddle Wheels of Steam Engines.*" By J. Grantham.

There are four cases in which it may be desirable to disconnect the paddle wheels from the steam engine in steam vessels, viz., when the vessel is on a long voyage, and the fuel must be economized as much as possible by using the sails on every favourable opportunity; when the engines are damaged, and, the vessel being close to a lee shore, it is necessary to disengage the engines quickly, to allow the vessel to make sail; when some derangement has taken place, and the engines are allowed to continue to work imperfectly to the end of the voyage, rather than detain the vessel by causing the paddles to drag through the water while the engines are stopped; when, the vessel being at anchor, the action of the swell and tide on the paddle floats, while stationary, causes a great additional strain on the cables, which would be obviated could the wheels play freely. The Admiralty had called attention to the subject, by inviting plans for effecting it. Several had been proposed for disconnecting the paddles, but Mr. Grantham is not aware of any plan having been proposed by which the wheels could be readily disconnected in a heavy sea. The crank pins are usually fixed in the cranks of the intermediate shaft, a little play being allowed in the eye of the crank of the paddle shaft, to prevent the crank pins from breaking when the centres of the three shafts vary from a straight line by the yielding of the vessel. For the purpose of disengaging and reconnecting, a brass box of a rectangular form is inserted in the eye of the crank of the paddle shaft, which can be moved several inches by means of a screw at the back of the crank. The eye of the crank is so made that two of its sides may be cut away, and through these openings the crank pin can pass when the box is drawn back, or the disengaging effected. The brass box has one of its sides, which restrain the crank pin when in gear, cut away one or two inches to assist in reconnecting the engine, which is effected by screwing the box out one or two inches, or just so far that the crank pin can pass the side which has been cut away, and come in contact with the higher side. This is the correct position for reconnecting, which is accomplished by a single turn of the screw.

Mr. Grantham, in reply to a question from Capt. Taylor, R.N., stated that he should consider it very dangerous to disconnect the paddle wheels without having first stopped the engine.

"*On the Propulsion of Vessels by the Trapezium Paddle-wheel and Screw.*"

Mr. G. Rennie gave an account of the various experiments to which he had been led, on the propulsion of vessels by various forms of paddle floats and by the screw. It was generally admitted that the paddle wheel was the best means of propulsion with which engineers were at present acquainted, and various attempts had been made for its improvement. There are several objections to the square or rectangular floats, particularly the shock on entering the water, and the drag against the motion of the wheel on the float quitting the water; both of which give rise to considerable vibrations. He had been led, in considering the improvement of the paddle wheel, to have recourse to nature; and the form of the foot of the duck had particularly attracted his attention. The web of the duck's foot is shaped so that each part has a relation to the space through which it has to move, that is, to the distance from the centre of motion of the animal's leg. Hence he was led to cut off the angles of the rectangular floats, and he found that the resistance to the wheel through the water was not diminished. Pursuing these observations and experiments, he was led to adopt a float of a trapezium or diamond shape, with its most pointed end downwards. These floats enter the water with their points downwards, and quit it with their points upwards, and then arrive gradually at their full horizontal action, without shocks or vibrations; and after their full horizontal action, quit the water without lifting it, or producing any sensible commotion behind. After a great variety of experiments, he found that a paddle wheel of one half the width and weight, and with trapezium floats, was as effective in propelling a vessel as a wheel of double the width and weight with the ordinary rectangular floats. The Admiralty had permitted him to fit Her Majesty's steam ship *Africa* with these wheels, and he had perfect confidence in the success of the experiment. Another means of propulsion was the screw, which had been applied with success by Mr. Smith in the *Archimedes*. In examining the wings of birds and the tails of swift fish, he had been particularly struck with the adaptation of shape to the speed of the animals. The contrast between the shape of the tail of the cod-fish, a slow moving fish, and the tail of the mackerel, a rapid fish, was very remarkable,—the latter going off much more rapidly to a point than the former. From these observations he was led to try a screw with four wings, of a shape somewhat similar to these, but bent into a conical surface, the outline being a logarithmic spiral. He found also that certain portions of these might be cut off without diminishing the effect. With respect to ascertaining the friction of the screw on the water, great difficulty existed; but he would refer to his experiments, published some years ago in the Philosophical Transactions, in which he measured the friction of the water against a body revolving in it, by the time which a given weight took to descend; this body consisted of rings, and he found that the friction or resistance through the water did not increase in proportion to the number of rings.

"*On a Floating Breakwater.*" By Capt. Taylor, R.N.

The breakwaters hitherto constructed have generally consisted of solid masonry, thus presenting an unyielding obstacle to the waves, and permitting accumulations of mud and sand behind them, and not affording the security to shipping and life which is required, and may be afforded by other means. The floating breakwater consists of floating sections framed of timber, moored to piles; these sections yield to the shocks of the sea, and admit the wave to pass under, over, and through them, and by thus dividing the waves, reduce them to an open and harmless state. The forms of these sections vary according to the situations in which they are employed. The sea in the most tempestuous weather is said to be tranquil at the depth of sixteen or eighteen feet below the surface; a breakwater, therefore, immerged to that depth, and presenting six or eight feet above the surface, is sufficient to form a safe harbour on the most boisterous coast. The angle of inclination which the section presents to the wave is that pointed out by nature in the [illegible], viz. 35 degrees. Stone breakwaters check the ground tides, and cause accumulations of mud and deposits which otherwise would go seaward, and are peculiarly subject to the action of the teredo, constantly at work below the dove-tailed stone; and cavities being formed, large portions are occasionally thrown up. The destruction by the teredo may be obviated or arrested in the floating breakwater by saturating the wood with a preservative solution, or by restoring from time to time such portions as are injured. The distinction between waves and breakers is very important, the former being an undulation, the latter being accompanied with a translation of the mass, and capable therefore of exerting extraordinary forces on the masses opposed to them.

Some remarks were made on statements in another Section, respecting the destruction to which the limestone of which the Plymouth Breakwater is exposed from certain animals (*Saxicava rugosa*). These animals do not, however, meddle with granite, and probably timber payed over with hot tar would resist their ravages, as animals of this nature seem peculiarly averse to the smell of tar and similar substances.

"*On Forms of Vessels.*"

Mr. Scott Russell reported the progress made by "the Committee on Forms of Vessels" during the past year. The object of the experiments is two-fold—to advance our knowledge of the laws of resistance of fluids,—and to obtain data for the practical improvement of the art of naval construction. Many and expensive are the experiments formerly made on this subject. Unfortunately, these experiments had been made with imperfect apparatus, or under circumstances different from the conditions of bodies moving on the surface of the water, or on solids of a form unsuitable to the formation of ships, or on so small a scale as to render them unworthy of the confidence of the practical constructor. In the present series of experiments a more simple apparatus was employed than in any former series of experiments. The forms of body experimented upon were those of actual ships, or bodies analogous to these in use: it was the object of the experiments to supply the actual desiderata of hydrodynamics and of practical ship building. The experiments were made on vessels of every size, from models of 30 inches in length to vessels of 1,300 tons. The experiments were also made upon vessels in water of variable depth and in channels of various dimensions, so as, if possible, to embrace all the elements of the resistance. A minute description of some of the apparatus was then given, along with some general illustrations; but as the experiments were still in progress, and to be continued during the following year, no general statement of results was entered into at the present meeting. It was expected that by the next meeting the whole would be concluded.

"*On Captain Couch's Chock Channels.*"

Mr. Snow Harris explained and illustrated, by a model and drawings, the safety chock channel, for allowing the masts and rigging of vessels to be easily disengaged when the masts are carried away. Many cases have occurred in which, with the rigging and ordinary channels, the greatest danger has been incurred, in consequence of not being able to get clear of wreck. The ordinary channels may be blown up by the sea; whereas, if made solid, on Capt. Couch's plan, all danger from this source will be avoided, and the sailors would be at once able to clear the vessel of any wreck.

"*On Arnott's Stove, and the Construction of Descending Flues, and their Application to the purposes of Ventilation.*" By J. N. Hearder.

The general advantages of Arnott's stoves in economizing fuel, avoiding smoke, and regulating the temperature, are well known; but these stoves are attended with some disadvantages, of which the danger of explosion, and imperfect ventilation, are the most serious. The liability to explosion, Mr. Hearder considers to arise from the construction of the stove, in having the door air-tight; the only aperture for air being the valve aperture of the ash-pit. The air so admitted is immediately decomposed, and nearly the whole of its oxygen is abstracted, so that by the time it has passed up through the fuel, and reached the upper chamber of the stove, it has not oxygen enough left to support combustion. The heat evolved by the lower stratum of fuel, acting upon the upper stratum of fresh or unignited fuel, liberates from it the inflammable gas which it contains, and which also accumulates in the top of the stove. A mixture is then formed analogous to the fire damp of coal mines, ready for explosion whenever the requisite oxygen or degree of temperature shall be present. Under these circumstances, should the door be opened, a burst of flame outwards may be the result; or should a puff of wind down the chimney carry the mixture down through the ignited fuel, an explosion may ensue. Other causes, such as the sudden shutting or opening of the doors of an apartment, may occasion the downward draught and consequent explosion. Now carburetted hydrogen will not explode when the proportion of the air to the hydrogen exceeds a certain limit, so that if air be supplied to the top of the stove, so as greatly to preponderate over the hydrogen, the latter will burn off in a flame at the moment of its formation, or be carried up the flue. Mr. Hearder, therefore, proposes as a remedy, perforations through the lower edge of the door, so that air may be admitted on a level with the top edge of the fire brick, through which a constant in-draught of atmospheric air will be insured, sufficient to obviate the evil. The heat evolved by the perfect combustion of this inflammable gas, under these circumstances, will, he says, more than compensate for the admission of cold air into the upper part of the stove. The perforations just mentioned will also obviate, in a great measure, the want of ventilation. The author suggests a small rarefying apparatus, to be inserted in the vertical shaft connected with a descending flue.

"*Some Experiments showing the possibility of Fire, from the use of Hot Water in warming Buildings, and of Explosions in Steam Engine Boilers.*" By Mr. Goldsworthy Gurney.

After detailing several instances of fire which arose from the steam pipes of water apparatus used for warming houses, the author proceeds to describe some of the experiments likely to be of practical value. From a tubular [illegible] was cut off—half an hour after the supply pump was stopped, no water appeared on opening the gauge cocks, and the engine was observed to slacken its rate and to move sluggishly—it had dropped from 50 to 30 strokes a minute. The steam pipe from the boiler to the engine was 40 feet long, and was carried for convenience through the open air, thickly wrapped round with woollen cloth to prevent radiation: soon after the engine became sluggish, the woollen cloth was observed to char near the boiler, which soon extended along the whole length of pipe; the engine still working, but with more apparent difficulty, making only 16 strokes per minute; the pressure gauge, which usually ranged between 30 and 40 pounds, now stood at 15, and was gradually sinking. In about five minutes after the woollen cloth had charred, a lead flange, used as a packing at the cylinder joint, melted, and was followed by a loud escape of elastic matter. The engine stopped working, and on bringing a lighted match into the escapage, it took fire, and burnt with the lambent flame of hydrogen gas. The author's impression was, that the escaping vapour was not pure hydrogen. Water condensed on a piece of cold iron held in the flame, but no water condensed on the cold iron after the flame was extinguished. On examining the boiler, all the tubes were found red hot. This experiment was repeated with many modifications. The temperature of the escaping vapour was ascertained by means of bars, previously prepared to melt at different temperatures; these indicated a temperature of about 400°. In about eight minutes a piece of pure lead melted—woollen cloth was charred, and a piece of tow held in the escapage took fire. In other experiments it was found, that the pipes became sufficiently hot to explode gunpowder, and many chemical preparations. Having satisfied himself of this property of heated steam or elastic matter, formed from the last portions of water in a boiler, the author proceeded to examine, as far as possible, its chemical nature—to determine whether any decomposition, or new elementary formation, took place. He found that the elastic matter was not condensible over cold water, and would not in many cases burn, or show any indications of the presence of hydrogen, or other inflammable matters. In some experiments it was found it would extinguish flame. The experiments with copper vessels afforded the same results as those manufactured from iron. From these experiments it appeared, that whenever the heating apparatus falls short of water, the elastic matter formed over the fire will carry sufficient heat through close pipes, to any distance, to set fire to wood and other combustible bodies, and that whether the hot water apparatus be under pressure or not, or whether the heating surface be of tubes, plates, or cylinders. On the other hand it would further appear, from some experiments enumerated, that in no case is there danger when a given quantity of water is present. Mr. Gurney suggests, that if both ends of the circulating series in hot water apparatus, namely, the part which immediately goes from the heating surface beyond the furnace, and that part where the circulation returns to it before it enters the furnace, was made of a metal which would not melt at the fair working temperature of the water, but which would melt at a temperature of from 5 to 600° of heat (say lead pipe), there would be little, if any, danger from fire.

It was mentioned that some experiments made many years since, by Woolfe, on some of the boilers of the Cornish steam engines, corroborated the facts now stated. It was also mentioned by Mr. Hunt, on the authority of Capt. Tregaskis, that where the boilers had been covered with sawdust, it was found in some instances, and in a very short time, to be charred.

"*Account of the Strata penetrated in sinking an Artesian Well at the Victoria Spa, Plymouth.*" By Dr. Edward Moore.

The author pointed out the mode by which the operations were conducted. The strata penetrated were as follows:—Earthy clay slate, 20 feet; limestone, 150; blue slate, 20; red sandstone, 3; red slate, 37; limestone, 50; sandstone, 4; red and blue slate, 30; dunstone, 8; earthy clay slate, 20; red sandstone, 12; making a total of 365 feet. The earthy slates were of the character of those generally found under the limestone, but they were interspersed with blue shillat slates, similar to those which occur above it. From the circumstance of the slate rocks immediately below the red sandstone being in each instance tinged red, the author imagined that their colour might in these cases, if not in all, arise from the iron of the red bands affecting them by percolation. He next remarked that from the alternations of slate and limestone, the former appearing, from a consideration of the section, to come up in wedges through the latter, it might be possible that the opinion that some of the Plymouth limestones might have been formed in a manner analogous to the modern coral reefs, was founded on correct data, although in many other localities in the vicinity the bands belong to the same uninterrupted series of deposits. The quantity of water obtained was at first considerable, and overflowed the pipe; at present it generally remains about two feet below the surface, from whence it is carried to the saloon by a pump; it is clear and sparkling, and of a saline taste; it has been examined by Professors Faraday and Daniell, and found to contain in the imperial pint 8·100 cubic inches of carbonic acid gas, and 151·66 grains of dry salts, thus:—

Chloride of Sodium	96·64
Muriate of Magnesia	18·68
„ „ Lime	15·10
Sulphate of Soda	9·55
„ „ Lime	8·94
Carbonate of Lime	2·06
„ „ Iron.................	0·69
	151·66

Its specific gravity at 62° is 1018·3.

[illegible] described two districts in which these operations were attended with very different results. In the eastern part of Essex the chalk is covered by sandy beds of the plastic clay, and these by several hundred feet of impervious strata of London clay, all dipping together towards the east. The arenaceous beds below the London clay rise higher towards the chalk than the clay does, and absorb a considerable part of the water from the high grounds. By boring through the clays to this sand, springs of water immediately rise above the surface, and are carried off by natural channels. By this supply of water, the value of the land has been materially increased, since the country, though abounding in peat bogs, and stagnant ponds during winter, suffers much from the summer drought. The other attempts to form Artesian wells, referred to by Mr. Sedgwick, were made near Lincoln, which, though surrounded by fens, covered with water in the winter, is not sufficiently supplied during the summer. But the clays supporting the fens of the Bedford Level are below the chalk, and though there are pervious beds beneath them, which rise to the north-west, yet the clays are of such enormous thickness that they have never been penetrated; and even were that accomplished, the high land is so distant that intervening fissures, filled up with impervious materials, might intercept the supply. Expensive sinkings have been made at Lynn, and also at Boston, and after boring through many hundred feet of clay they have utterly failed, and in any future operations in this district the chance of success would be very remote. Mr. Sedgwick then observed with respect to the red colour of rocks mentioned by Dr. Moore, that he considered it simply owing to the red oxide of iron which might be present or not in any bed; sometimes the tinge was only superficial. In Nassau the red colour was owing to vicinity of trap rocks. He also observed, as to the condition of limestone rocks, that although they sometimes appear in masses, presenting a brecciated appearance, shells and broken corals being cemented together, yet generally they occur as regular parts of the series repeated without any regularity, in formations of all ages. In position and inclination they resembled their associated rocks, and partook in all their contortions and dislocations, except so far as their solid masses would resist mechanical movements, better than yielding deposits of sediment and mud. The organic remains found in limestones only differed from those in the other beds of the same age as far as the conditions differed under which each was deposited. At the present day different families of corals grow upon a solid and a soft bottom.—The Rev. W. D. Conybeare pointed out the similarity between Artesian wells and mines sunk in the coal measures. Artesian borings had been made with success near the outcrop of certain strata, but at a distance from this, although the combination of strata was the same, they had failed, from the great depth necessary to be penetrated. Now it is certain that the coal exists in many places beneath the new red sandstone and magnesian limestone, but at such depths that it would be hopeless to attempt to reach it. He therefore recommended to the attention of miners the formation of a series of Artesian borings in some of the coal districts, beginning where the probability was greatest, and proceeding from that point till the depth became too great. Such a series of experiments would show the nature and depth of the strata below, and over what extent coal might be worked without sinking shafts at enormous expense and with the risk of complete failure.—Mr. Bartlett observed, in confirmation of one of Dr. Moore's remarks, that where limestones abounded in corals, as at Berryhead, their structure was homogeneous, and exhibited little trace of stratification; when the corals were rare, the bedding became distinct.

"*Some Inquiries into the Causes of the increased Destructibility of Modern Copper Sheathing.*" By Mr. Prideaux.

In May 1840 Mr. Prideaux was applied to by Mr. Owen, of Her Majesty's dock-yard, to analyse some sheet copper from the sheathing of the *Sanspareil*, which had been on thirty years, and was still in good condition. The sample gave about 0·25 per cent. of alloy, chiefly zinc and tin. This contrasted well with a sample rendered unserviceable in a very short time (in only one year), and in which no quantity of alloy sufficient to weigh had been found; and the two agreed with two recorded analyses of Sir H. Davy and Mr. R. Phillips, the former having detected, in a very good sample of sheathing, about $\frac{1}{150}$ of tin; the latter having found the sheathing of the *Tartar* frigate (almost destroyed in four years, though never out of Sheerness harbour,) the purest copper he had ever analysed; and further with the reputed inferiority of the recently prepared sheathing of the Royal Navy, which must have been much purified by the repeated fusions it has undergone. The inference adduced was, that the presence of tin and zinc was favourable to the durability of the copper. Mr. Prideaux, however, proceeded with the analyses in other cases. Four were selected, viz.

From the	Copper on	Annual loss.
Minden	17 years	0 45 per cent.
Plover	only 5	11

Linnet, copper rapidly destroyed, could not be taken off sound enough to weigh a sheet.

New-sheathing prepared at Her Majesty's mills, Portsmouth.

There was no conformity between the results in these and the former experiments; they did not show any coincidence between the composition of the sheathing and its durability. The next step, therefore, was to examine [illegible] the physical properties of the metal. To ascertain this, slips from each sample, all of equal surfaces [illegible], were [illegible] side by side, so as to [illegible] them all in [illegible] neutral, and [illegible] quicken the action without affecting the [illegible]. The [illegible] on the *Sanspareil* copper, which had worn the best of all [illegible] of the *Plover*, one of the worst. Thus, in the laboratory, under [illegible] circumstances, they do not observe the same order of durability and waste as they had done in use. The cause of comparative waste appears, therefore, to be in part at least, due to *external conditions*, and of these two classes may be noticed: one depending on the connexion with the ship, the other on the circumstances of her employment. Of the first class two suggested themselves—the position on the ship's side, and the nails by which the copper is fastened. The lower part of a ship's copper seems to suffer much less than the upper, so long as she continues in deep water; but when she grounds at low water, if on black mud, this part suffers most from the action of sulphuretted hydrogen, peeling off in blue flakes. The influence of the nails offers rather more chemical interest. They are never of pure copper, and being very numerous, all in contact with the copper sheets, whilst their heads present also a considerable metallic surface to the salt water, they may produce very decided effects, either preservative or destructive, by a slight electro-chemical difference. Mr. Prideaux therefore examined a vessel which they were just then stripping, her copper being worn out in four years. It was found that round some of the nails the copper was quite entire, for an inch or two, though worn ragged in other parts; whilst elsewhere, and sometimes on the same sheet, the copper round other nails was quite gone, though other fragments of the sheet remained. Here some of the nails appeared to have exerted a protective, others a destructive influence. To ascertain the effect of the nails, five slips of new copper from the same sheet, and of the same size, were suspended equidistant, and at the same depth, in a vessel of sea water from the West Indies. The result was, that all the nails, except one (which was from Her Majesty's dockyard), appeared to act destructively. Here appears to be *one* instance of a protective nail, not enough so to prevent all waste of the copper, which experience has shown not to be desirable; but doubtless the preservative power may be increased to any requisite degree by attending to the composition of the alloy. The copper is alloyed chiefly with tin; but if the nail is at once hard and flexible the manufacturer is satisfied without examining what other metals are present. If they were always made just so much electro-positive to the copper as to protect the sheathing, so far as compatible with their own durability, they would seem to offer the simplest, most perfect, and most convenient means of electro-chemical protection. The damage to which the copper is subjected is affected by the circumstances of the ship's employment. Sheathing suffers most where most subject to wash and air, for friction is an agent in the waste as well as oxidation. It is also well ascertained that the copper sheathing suffers most in hot climates, which might be expected, upon a common chemical principle, that chemical action increases with the temperature; and it became a question whether this effect of heat, as well as its tendency to promote organic production and decomposition, might not form an important element in this destructive agency. Mr. Prideaux therefore obtained water from different parts of the Gulf Stream, with and without the weed, from the Caribbean Sea, and from Falmouth harbour, where the packets moored, the waters of which might possibly be affected by the mine drainings discharged into the river. Whilst these were being collected, Prof. Daniell's announcement of large quantities of sulphuretted hydrogen in the waters of the Guinea coast came before the public. To try the action of these different waters five copper slips, of the same dimensions, cut from the same sheet, were suspended in a pint each of the following samples of water:

1. Heart of the Gulf Stream.
2. Ditto with the weed.
3. Caribbean Sea.
4. Falmouth harbour.
5. Plymouth harbour.

After thirteen days they were taken out and reweighed, having been put in all bright, but cleaned, on taking out, only with a brush in soft water, as in the other experiments:—

	1.	2.	3.	4.	5.
Put in 16th........	180·26	182·56	190	169·01	176·41
Out 29th ;.........	178·45	182·3	189·6	168·55	176·1
Loss in 13 days....	1·81	0·26	0·4	0·46	0·31

No. 1, came out clean and bright, the others with tarnished surfaces, except No. 2, which was blotched and speckled. The Falmouth water presented no indications of being more corrosive than that of Plymouth, and Mr. Prideaux attributed the great difference of waste in these two cases to some unobserved difference of conditions in the experiment. But the excessive action of the Gulf Stream water, he considered too decided to be doubtful. Not only the quantity wasted, but the metallic clearness of the surface, showed a marked distinction. "But to whatever extent the recently increased waste of sheathing may fairly be charged upon the greater velocity, more constant employment, and greater consequent liabilities of weather and climate of our ships, particularly of the commercial classes, as well as to differences in the nails, I am inclined," said Mr. Prideaux, "to fear the fault is still to be [illegible] copper itself. I have it on the authority of Mr. Moore, [illegible] generally at anchor in any harbour, was [illegible] [illegible] is now [illegible] [illegible] years. The Eddystone [illegible]

[illegible] to July [illegible], and is now in much worse condition than the [illegible], which has been on six years longer. That the waste on the Eddystone tender is not owing to her work, is evident, from the fact, that the upper part of her sheathing, which suffers the wash and friction, continues sound, whilst from beneath her floor the copper peels off in blue flakes. That this is attributable, in a great degree, to her occasionally grounding upon the black mud, which generates sulphuretted hydrogen and other corrosive matters, is very probable; the other never grounds, and does less work. Yet the difference is too great to be thus satisfactorily accounted for. The one is in good condition for nine years, the other comes to patch before the end of three: both lying the most of their time in the same harbour. On neither was there any distinct indication of protective or destructive influence in the nails." "Meanwhile, as nails must be used, and present a large metallic surface to the salt water, as well as numerous points of contact with the copper, calculated to give great effect to small electro-chemical differences, either in protection or destruction, it would seem that we ought to render them slightly electro-positive to rolled copper, by the addition of zinc, which would not injure their flexibility nor enhance their cost. The test, by the galvanometer, would be easily applied (after a little practice) in making up the metal for casting them, if it is of importance to continue the present system of their manufacture."

There is another method of protection, which came out in the course of these investigations; and which is beginning to occupy public attention. It was before noticed, that the upper part of the copper on the Eddystone tender, which bears the wash and friction of the waves, continues sound; whilst the bottom is fast wearing out. This exception, or rather subversion of the usual conditions, is owing to a coat of fish oil, laid on when the copper was new, to keep it bright; and not extended over the parts out of sight. Such a permanent effect could never have been anticipated from an oil which is not drying, and strongly indicates the facility, as well as efficacy, of this mode of protection. A still more striking case presented itself in the vessel which supplied the observations on the apparent influence of the nails. During our examination, we observed the complete preservative effect of some coal tar, which had trickled down over the copper, from the wood-work above. This had crossed the sheets just where most subject to the wash and friction; and whilst the naked metal had been quite worn away, the coal-tarred streaks remained entire, the surface of the copper, on melting off the tar, being as perfect as when fresh from the roll. Hence coal tar seemed to be an efficient preservative; but then recurs the question—will it keep a clean surface, free from organic adhesions and earthy incrustations? To embrace the opportunity for experiments, the vessel was sheathed with copper on one side and yellow metal on the other; and her fore-quarters to her mid-length varnished with coal tar, laid on hot, upon the metal also heated, by fires of chips round the sides. She has now been twelve months at sea; and, according to the last account, the varnished as well as the metallic surfaces, kept quite clean.

METHOD OF PREVENTING THE OXYDATION OF IRON.

By M. F. L. Allamand.

This composition, of a metallic nature, preserves iron and steel from oxydation, by entering into the pores without in any degree affecting their external appearance, or leaving the least blemish, so that steel instruments (including razors), fire-arms, &c., retain their polish, and are in some degree better fit for use, after having been subjected to the metallic application. Articles either plain or chased appear superior to platina, and retain, after the application, all the hieroglyphic characters, figures, letters, and other engravings, or cuttings, which were there previously.

COMPOSITION OF THE MATERIAL.

Pure Malacca Tin	120
Silver filings	4
Yellow tincal	12
Purified Bismuth	12
Purified Zinc	12
Regulus of Antimony	4
Nitre	11
Salt of Persicaria	1

Method of Purifying the Metals.—The tin ought to be melted separately 12 times. Each melting should remain about 20 minutes exposed to the action of caloric, and the impurities which arise on the surface should be carefully removed; it is thrown afterwards into a ley formed of vine twigs and persicaria (herb) in equal proportions. The bismuth, the regulus of antimony, and the zinc are also melted separately, but they only require it twice, and they are carefully run into an ingot mould, so that all impurities may remain at the bottom of the crucible. The tincal does not require any purification.

Mixture of the different substances.—The tin is the first material that is melted; the silver is afterwards added to it in small quantities, and in a few minutes afterwards the tincal, then the bismuth and the zinc in succession. As soon as it is ascertained by the flames that the alloy is affected, the two kinds of salt are thrown in together, and are left to burn with vigour, and the alloy is stirred with an iron rod; after which it is carefully skimmed and poured into a vessel, to be made use of for the metallic application.

Method of applying the substance.—Before the piece of iron or steel is dipped in the recipient which contains the metallic mass already liquified, its surface must be rubbed well with a composition of sal-ammoniac and cream of tartar, in the proportion of 5 per cent. of tartar to the sal-ammoniac; the iron must then be dipped in the melted alloy, where it must remain only for a few seconds, and till it is perceived to be covered with a certain quantity of the metal. It is next placed in a wooden box of its own size, and in which there has been previously put a small quantity of sal-ammoniac and cream of tartar, in the proportions already indicated. It is again rubbed with a handful of tow, and a small quantity of the powder is put on the surface. In the course of this operation the steel loses its colour, and assumes that of silver. When this is done it is again plunged into the metallic mass for a few seconds, and when it is taken out it is again lightly rubbed with the tow to remove any superfluous particles. The article being perfectly clean and shining, it is plunged into a basin of cold water, into which there has been poured a bottle of spirits of wine of forty degrees of strength, in the proportion of ½ per cent. After having withdrawn it from the water, the article is rubbed carefully with a linen, then it is rubbed as carefully with some fine sand, that has been moistened, to remove the spots of smoke: it is at last rubbed a second time with dry sand, then with a linen, and finally with a leather. After all these operations, which require great celerity in the execution, the iron will remain impervious to oxygen, and by care it will preserve all its whiteness.—*Inventors' Advocate.*

APPARATUS FOR DISTILLING SEA WATER.

We have seen in operation, at Mr. Robinson's manufactory, Pimlico, an apparatus for evaporating water in large quantities. An authentic account of the apparatus has been given in the *Inventor's Advocate*, from which we give the following details:—

The principle on which the patent "Distillator" is constructed, is that of the continuous transfer of heat through a series of vessels by evaporation. Thus, steam being generated in the boiler, is admitted into a chamber surrounded by water, where it is condensed, forming distilled water. From that chamber the water is permitted to run off into a suitable vessel. The heat transferred from the condensed steam to the water with which the condensing chamber was surrounded, produces renewed evaporation, and the steam from that second boiler is conveyed to a second condensing chamber placed in a third vessel of water. The process is repeated in that vessel, and may be so continued through five or six condensing chambers. In the apparatus we inspected at Pimlico there are only three condensing chambers, and the hot water in the last vessel is pumped back to the first boiler until it becomes saturated with salt, and then it is blown off.

As in the ordinary process of distillation only one condensing vessel is used, it is evident that a positive saving of fuel must arise from the addition of other vessels in which a similar process can be carried on without the addition of fresh fuel. In the apparatus already constructed, it is found that by the addition of two chambers to the ordinary still, an increase of distilled water is obtained equal to from 130 to 140 per cent. The produce of the three condensing chambers, at a *minimum*, are three measures from the first, two from the second, and one from the third; the two last being equal to the evaporation from the boiler heated by fuel. At a *maximum* the quantities are: from the first, five measures; from the second, four; and from the third, three. This is equal to a gain of 140 per cent.

In the report of experiments made to the Lords Commissioners of the Admiralty, it was proposed to produce 20 lb. of distilled water by the combustion of 1 lb. of coals. This was actually produced by the apparatus, under a working pressure of steam in the boiler of 10 lb. to the square inch; but, as in subsequent trials, the working pressure has been reduced to 5 lb. the square inch, as a measure of safety, the effect falls short of 20 lb. of water for 1 lb. of coal, in a slight degree; but in a new apparatus, this can be amply compensated, by giving an increased evaporative power to the first boiler of the series, and by coating the whole with felt, so as to prevent the radiation of heat. In a trial of three hours duration, 59 gallons were evaporated from the three vessels as now constructed.

It is proposed, as a matter of convenience and safety, when the apparatus is employed on board ship, that the fire should be placed on the upper deck, and the distilling or condensing chambers on the lower deck, or in the hold. By this arrangement it is expected that the same fire which is used for cooking may be made the means of producing a constant supply of fresh water.

By the use of this invention, the necessity of encumbering a vessel with the usual cargo of water and tanks for a long voyage is entirely obviated, by merely substituting five per cent. of that cargo in coals for the distillation.

FRESCO PAINTING.

Mr. Haydon, with characteristic energy and enthusiasm, has made a trial in fresco, on the wall of his painting room; and the result of this first and hasty attempt is decisive of two important points—the beauty of fresco painting as a means of decoration, and the ease with which a knowledge of the practice may be acquired. The subject is a study for the archangel Uriel, the bust and arms only, of the life size; it was painted at once on the plaster, without a cartoon to work from, in four hours; the painter's hand trembling with apprehension for the success of his experiment, and incompetent from inexperience to do full justice to the means. It is a rough sketch, in short, made without the boldness and firmness of pencilling that certainty of purpose and mastery of hand alone can give. Yet the figure stands out from the wall, solid in form, lively in colour, and brilliant in tone, making the pictures beside it look poor, flat, and muddy in comparison; its flesh tints surpassing in purity the freshest oil painting. It has a majestic presence, that seems to enlarge the space it occupies, and to give new radiance to the light reflected from it; but while it thus fills the sense and elevates the mind, it is not obtrusive. In describing the impression made by this piece of fresco, our object is not to compliment Mr. Haydon, or to praise his design. We do but record the effect produced upon us by the work; though the conception and style of the painter must have had their share in producing this impression, we endeavoured to regard only the physical qualities of the art. The large scale of the design and the breadth and simplicity of the painting, have unquestionably a material influence over the mind; but these characteristics belong to all fresco, and constitute its chief recommendations; the greatness of the style powerfully aids the grandeur of the idea, and the largeness and boldness of the handling inspire the painter with congenial vigour of execution, which the cartoon he works from would prevent from running into exaggeration. As the tendency of high finish in cabinet pictures is to contract the focus of the mind and cramp the execution, so that of fresco is to enlarge the conception and expand the style. Fresco painting is the school of greatness in painting; it daunts and depresses only the little mind; it fires and elevates the noble and aspiring genius; the artist works with that grand gusto of which we hear so much and see so little. Mr. Haydon tells us, and we can well believe, that there is a fascination in the very manner of painting which is inspiriting and stimulating to fresh exertions; and he now regrets not having followed the advice of Sir David Wilkie twenty years ago, to apply himself to fresco. Any zealous artist might easily make the experiment; the same means of information are open to all. The book authorities for the Italian method, we are told, are Vasari, Armenini, and Cennini. Messrs. Latilla, of London, Bell, of Manchester, and Barker, of Bath, are the artists in this country whom Mr. Haydon consulted; Mr. Lane, of whom we spoke, is not, we believe, in England. The method is simple; chip off the outer surface of the plaster from a dry wall, and substitute for it a coating of wet plaster, composed of two parts of river sand and one of lime, well mixed together with water to a proper consistency; this applied to the wall will remain sufficiently moist to work upon for four hour; no greater space should be plastered at once than can be covered in that time. Every touch is indelible; but it may be gone over again when the plaster is moist. The pigments used are of the common kind, being earths, and are dissolved in water; the lime itself is white; the difficulty is to allow for the change of tint in drying.—*Spectator*.

REVIEWS.

Illustrations of Arts and Manufactures. By Arthur Aikin, F.L.S., F.G.S., &c., late Secretary to the Society of Arts. London: Van Voorst, 1841.

Arthur Aikin is the scion of a literary house prolific in respectable names—we need only mention Dr. Aikin, Lucy Aikin, and Mrs. Barbauld. For a long while he was, as Secretary of the Society of Arts, the friend and adviser of the majority of the mechanical world, and well did he sustain his own position and the character of the institution. As a popular lecturer on subjects connected with the practical arts few could exceed him, for while he possessed the art of riveting the attention of his auditory, he was remarkable for a precision of idea and expression, which, even without the aid of diagrams or engravings, enabled him to give complete and correct ideas of most intricate and complicated machinery. So well was this known to be Mr. Aikin's characteristic, that Lord Brougham, himself no mean authority, is reported to have recommended a friend to apply to Mr. Aikin, as he knew "no other man but he who could make a specification without drawings." When Mr. Aikin retired from the post, which he had occupied so long, it was to the general regret, but still we hoped that one who had led a life so active and useful as his has been would not remain idle in his retirement, although he has well earned repose. We feel pleasure, therefore, in welcoming this first fruit of his retirement, which, as it is natural, is devoted to his ancient pursuits and connected with his former haunts. It is, what it purports to be, illustrations of arts and manufactures; it may, indeed, be considered as a manufacturing sketch or series of essays. The subjects treated on are pottery, limestone and calcareous cements, gypsum, furs, felt, bone, horn, &c., iron, engraving and paper. In their original form these papers were delivered before the Society of Arts, at their evening meetings, where we recollect the interest they excited; their republication therefore is likely to prove valuable.

From the article on pottery we have, at another page, given long extracts relative to brick-making, so that we cannot do better than here to take up the subject of limestones and calcareous cements. After tracing the origin of cement to brick-building countries, in the use of bitumen in the plains of Babylon. Mr. Aikin proceeds to allude to the improvements in its application which were made by other nations. To the Romans, however, he justly awards the palm among the ancients for their use of calcareous cements, on account of the extent to which they applied it in hydraulic works. They had also an advantage in discovering the use of puzzolana (vide C. E. & A. Journal, Vol. IV. p. 300.)* In alluding to the monuments of the Romans in this country our author says that the most ancient limestone quarries in this part of the empire, and which continue in full activity, were first opened by the Romans at Tadcaster, in Yorkshire, which, in the Roman itineraries, is named Calcariæ. In giving this praise to the Romans, it is to the Gothic style that we must refer the great extension given to the use of cement, the intricacy and elaborateness of its parts, its richness and multiplicity of ornament, not allowing the use of large blocks of stone. Limestones, Mr. Aikin divides after the usual arrangement into four classes. The first contains the pure limestones, including white statuary marble (which is of no use for mortar), white chalk, oolite, and gray limestone. In the second family are placed the swinestones and bituminous limestones, which are of value. Magnesian limestones come next, and lastly limestones containing so large a proportion of iron and clay as to enable them to form cements, which have the property of becoming solid under water, and are for this reason called water or hydraulic cements. (On this subject see also M. Vicat, p. 3 of our present volume). Among these are gray chalk, chalk marl or Dorking lime, found in large quantities at Dorking, Merstham and Halling; blue limestone, lying betweeen the lower oolite and the new red sandstone running across the country from N.E. to S.W. from Whitby to Lyme Regis, sending out a branch to Monmouth and Glamorgan. The entire thickness of this deposit is 450 feet, and among its chief quarries are Watchet, Aberthaw, Barrow and Bath. In the three former, according to Smeaton, the proportion of iron and clay appears to be the same, or about 11 per cent., but in the time of Barrow, according to that authority, 21·3, but according to Mr. Marshall, 14. In the upper and lower beds of the lias formation, and in all deposits of bluish slaty clay containing carbonate of lime, are balls of a compressed globular figure, less clayey than the slate marl, but less calcareous than the limestone. In the London basin these balls in the blue clay are called septaria or cement stone. They may be observed in the cliffs of London clay forming the eastern coast of the Isle of Sheppey, and in the low cliff at Southend in Essex. They were met with frequently in the cutting for the Highgate Railway and Primrose Hill tunnel. Of late years these stones, burned and reduced to powder, have been very extensively used under the name of Roman cement, in all water building and other masonry requiring particular care, with such success as to have entirely superseded the employment of puzzolana and terras. These two materials should also be noticed; the first comprehends a few calcareous substances, the essential ingredients of which appear to be oxide of iron and burnt clay; the latter is quarried at Andernach on the Rhine for millstone, and the fragments are ground up in Holland, and mixed with lias lime to form a cement for dykes and other works of the water-stant. In England, Rowley rag, a basalt obtained from the Rowley Hills in Warwickshire, and in composition similar to the Andernach stone has been used for the same purposes with good effect. The Egyptians, as it will be seen under the head of Ancient Engineering, used black basalt from Abyssinia, With regard to sand, the use of pit-sand is objected to unless previously cleaned by washing, but sand having a yellow colour, caused by ochre, and having chalybeate springs rising from out of it, will produce a cement of great hardness, provided that it be used soon after it is dug. But limestone and sand are not enough of themselves: the limestone must be deprived of its carbonic acid, and used as soon as possible, as it reabsorbs carbonic acid from the atmosphere. When packed in close casks, lias lime will keep good for a long time, and Smeaton's experience goes as far as seven years, but in this case, the lime was previously reduced to powder by slacking with water, and then was trodden down into the casks. The lime having cold water poured upon it, becomes hydrate of lime or slacked lime, and in this state and not that of pure lime, enters into the composition of mortar. The proportion of sand in mortar depends partly on the fineness or coarseness of the sand itself,

* It was an ancient law in Rome says Pliny, that after the ingredients of mortar had been rubbed together with a little water, the mass should be kept in a covered pit for three years before being used; and we are expressly informed that buildings erected during the operation of that law were not liable to cracks.

and partly on the nature of the lime, but on account of the cheapness of sand there is always a disposition to deteriorate mortar by a too liberal employment of it. The proportions given by Pliny are 1 of lime to 4 of sharp pit-sand, and 1 of lime to 3 of round grained sand from the sea or river, an improvement, he says, may also be made by the addition of a third part of pounded tiles. The common London mortar is made of one part of white chalk lime and 2½ of clean sharp river sand, but not unfrequently, dirty pit-sand is substituted, and the lime itself, being imperfectly burnt, the mortar never becomes hard, and has not sufficient adhesion to the bricks. White lime, when really good, will take a larger proportion of sand than the brown limes do, but it is an additional proof of the badness of common chalk lime, that in the London practice the reverse generally prevails.

Upon the question whether any chemical action takes place between the lime and silica in mortar, Mr. Aikin admits that it is difficult to come to a decision, but he alludes to several facts which seem only explainable by the existence of chemical acts.

In enumerating the water cements our author states, on the authority of Vitruvius, that the cement used by the Romans in the construction of moles and other structures in the sea, was one of lime and two of puzzolana, from which the proportions of Mr. Smeaton's cement, used in the construction of Eddystone Lighthouse do not materially differ, namely, equal quantities of Aberthaw lime in the state of hydrate and in fine powder, and of puzzolana also in fine powder; the cement was also well beaten till it had acquired its utmost degree of toughness. The Dorking gray chalk is used in proportions of 1 of lime to 3 or 3½ of sharp river sand; and for filling in the interstices of thick walls, 1 of lime to 4 of coarse gravelly sand. In setting the bricks, that form the facing of the London Docks to the depth of 14 or 18 inches from the outside, a cement was used of 4 lias lime, 6 river sand, 1 puzzolana, and 1 calcined iron stone.

This sketch of Mr. Aikin's mode of treating one subject will be sufficient to give an idea of the work, which we leave with the conviction that it is one highly useful and instructive.

Letter from Sir Frederick Trench to Viscount Duncannon. London: Ollivier, 1841.

In this letter Sir Frederick proposes a railway from London Bridge to Hungerford Market, to run in the river parallel to the northern bank. This is to consist of an embankment one mile and three quarters in length, faced with stone or plates of cast iron to imitate stone; on this, 4 feet above high water Trinity mark, is to be a promenade, bearing on iron columns, 13 or 14 feet high, a railway thirty feet wide, to be worked by fixed engines on wooden rails. At intervals in the embankment are to be arches for the passage of barges. The embankment, railway and all, as far as we understand is intended to pass under the arches of the bridges. With regard to the bed of the river between the channel and the shore. Sir Frederick proposes to leave it as a space for a carriage road, wharfs, warehouses, houses, docks, or open mud banks as the case may be. The estimate given on the authority of Mr. Bidder and Sir Frederick Smith is, for the embankment £110,000, elevated platform £100,000, machinery £70,000, stations £25,000, interest £30,500, for filling carriage road, paving, lighting and sewers £100,000. Total £435,500. The time for the works is calculated at two years.

Sir Frederick urges the necessity for an embankment on account of the changes made by London bridge and the embankment before the new Houses of Parliament, from which he says have resulted a great increase of shoals, and the production of a number of mud-banks covered with vegetation, and in a pestilential state of decomposition. These are evils which are but too apparent, and it is evident both as a measure of health, commerce, and ornament, that some plan of embankment should be adopted, whether Sir Frederick's, Mr. Walker's, or Mr. Martin's, we do not say; but we feel sure that the day is at hand when a great and general improvement will be effected on the metropolitan river, and placing it on a par with its Parisian and Dublin rivals.

To the plan of Sir Frederick Trench there are many objections, and some, and not the least, are those suggested by considering it as a plan for the adornment of the metropolis. Passing, as this railway proposes to do, through three bridges and touching a fourth, it is evident that it will not only abstract from the grandeur, but absolutely spoil the view of those noble monuments, without any adequate compensation. The view of Somerset House will not be improved, and St. Paul's will be the only edifice which will derive any advantage, so that on that ground we fear that any measure so extensive is inexpedient. How the railway is to pass under the bridges we confess we do not see, and as to passing over them, it is out of the question. A stronger objection is as to the effect such an embankment will have in producing depositions of silt and off below Woolwich, which may be looked upon as a certain result. As to the estimates, although a good foundation may in most places be obtained, we are decidedly inclined to think that they are too low.

We are willing, however, as we before said, to support some plan of embankment, but one so general we do not think under all circumstances is applicable. That the terraces of the Temple, of Somerset House, of the Adelphi, and of Hungerford Market, should be united, we are ready to admit, but we are well aware that there are great difficulties in the way. As to the consideration of making a profit from the undertaking, we think that they need not be taken into account on the present occasion, for the urgency of some plan of embankment is such that the funds must be furnished regardless of any other objects than the public benefit to be effected.

In thus dissenting from the details of Sir Frederick Trench's plan, we cannot do so without expressing how much the public are indebted to the gallant General for the great exertions he has made for the improvement of the Thames, and how much the successful result will be owing to his counsels and active co-operation.

CANDIDUS AND THE VENTILATION FOLKS.

"Cease rude boreas, blust'ring railer."

This humble petition is addressed to Candidus, who last month took out "a licence to blow on whom he pleases." We pray that he may abate his sweeping gale against the "ventilation folks," who most humbly acknowledge their fault in daring to acquaint the public that carbonic acid gas from a chimney—or sulphuretted hydrogen from a drain, do not strengthen the lungs, refresh the nerves, and invigorate the constitution. We will say with Candidus that the vocation of a tailor is more conducive to longevity than is that of a ploughman—that there is real salubrity below deck under London Bridge—even that a cargo of slaves enjoy the most refreshing change of air, and that their sickness and death of 50 in a hundred, is a proof of their sullen ingratitude to their owners. We will say that the metropolitan improvement trustees are egregiously in error not to consult Candidus. That old London may be revived with its neighbour-like projections, its lanes and alleys, so contributary to disease; its overground kennels, its annular visitation of plagues and pestilence, its lamentations and cries, bring out your dead; we will turn all serious proofs of modern blessings into frivolity for a month. We will say with Candidus, that the great orb of day, "is sun or moon, or a penny rushlight," to appease his anger; and when in cool reason he will debate upon this question upon which we live and die, "we will argue with him upon this theme until our eyelids will no longer wag."

Some of the Ventilation Folks.

THE NEW ROUTE TO INDIA BY THE EUPHRATES.

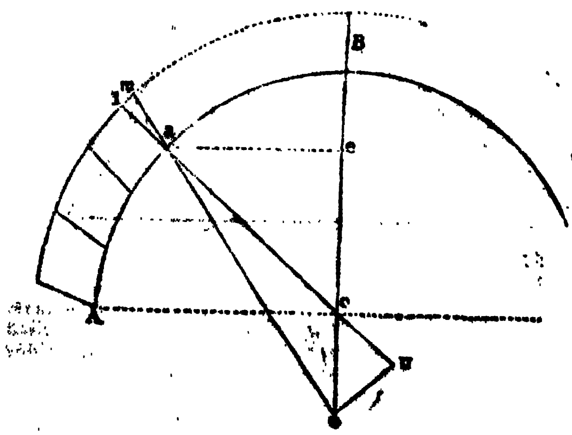
The *Commerce* publishes some private correspondence dated Aleppo, June 10, 1841, which states that the English steam boats Nimrod and Nitocris had arrived at Beles, on the Euphrates, after a navigation of 16 days and a distance of 375 leagues. Lieutenant Campbell, who commanded the expedition, had ascertained that both the Tigris and Euphrates are navigable for large vessels, and that those rivers present a new passage to the British possessions in India. "Documents stolen from M. Lascaris at Alexandria, in the year 1814," continues the writer, "contained important information collected by this gentleman. who was despatched by the Emperor Napoleon to explore Mesopotamia and the Euphrates, in order to ascertain the possibility of discovering a passage to India by the Orontes. The British Ministry determined to verify those plans. Colonel Chesney was deputed on this mission in the year 1835. Great Britain then ascertained that the Orontes, which falls into the Mediterranean, was navigable as far as Latakia (the ancient Antioch). That the ancient harbour of Selencia, situate at the mouth of this river, could be rendered an excellent harbour at a small expense. That it was easy to make a road to Aleppo, and thence to the Euphrates through the vallies, and that the distance, 45 leagues, could be easily traversed. A coal bed was discovered at the foot of Mount Taurus, 10 leagues from Tarsus. Near this coal bed, which is of considerable extent, has been discovered an iron mine, which gives 60 per cent. of metal. These mines are surrounded by oak woods of great value.

The writer calculates that the journey may be made from Bombay to Liverpool in 34 days—viz., from Bombay to Beles 16 days; from Beles to Alexandretta, 3 days; thence to Liverpool, 15. The latter concludes by stating that there is no doubt but that in a few years the English will monopolize the trade of Bagdad, Bassora, Aleppo, and all Mesopotamia.

ON THE CONSTRUCTION OF OBLIQUE ARCHES.

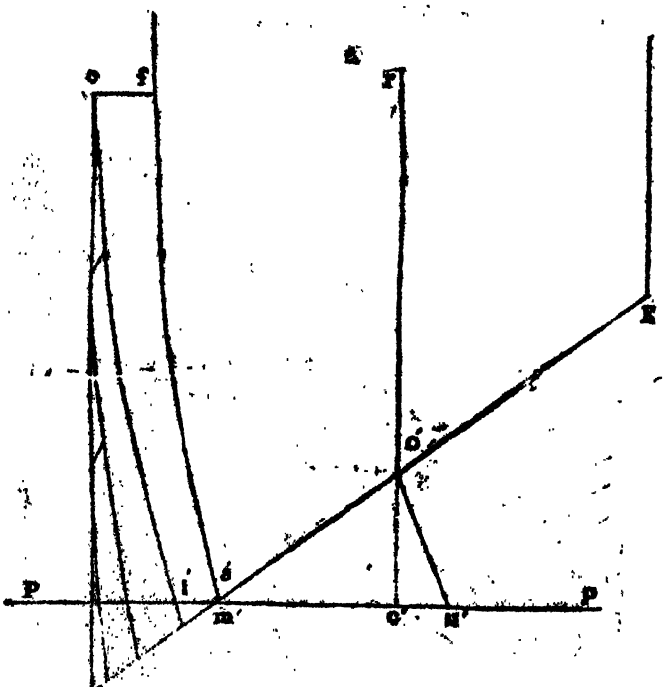
Sir,—In compliance with the request contained in your letter of the 10th, I forward you the method by which the formula and construction given in your last number, for finding the angles between the joint lines in the face and soffit of an oblique arch, were obtained. The approximations thus arrived at are as accurate as it is possible to work to, the discrepance being much too small to be detected practically. As the subject is somewhat complex, I must be excused if the explanation here given is not strictly mathematical, the deductions however will be found correct.

Fig. 1.



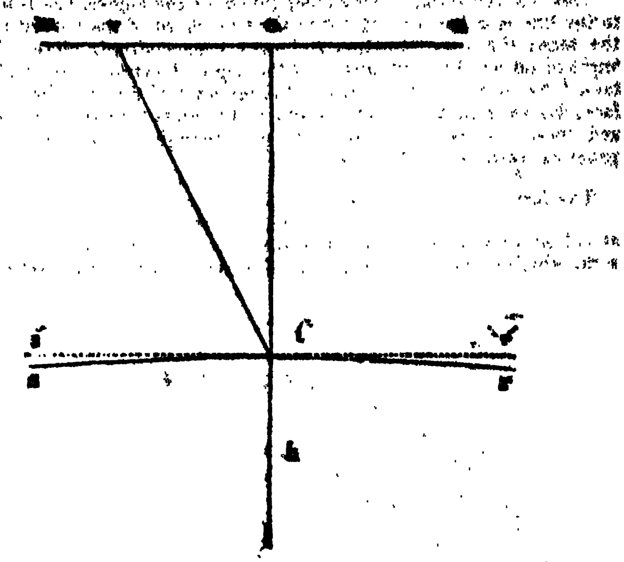
Let A B (fig. 1,) be the elevation of an oblique arch, on a plane at right angles to the axis of the cylinder on which it is formed, and let c be the centre, and a the point at which any joint $a\ m$ in the face of the arch meets the intrado.

Fig. 2.



Let C D E (fig. 2,) be the plan of the same, (part of the arch being supposed to be removed), and let a' be the position in plan of the point a (fig. 1.) Suppose a vertical plane P P to pass through the point a', intersecting the spiral surface $c\ f\ a'\ m'$ in the line $a'\ l'$. From l' let $l'\ m'$ be drawn a tangent to the spiral line of the extrado meeting D E in m'. And because the plane P P is perpendicular to the axis of the cylinder, the line of intersection $l'\ a'$ will be a straight line at right angles to the tangent $l'\ m'$. The triangle $a'\ l'\ m'$ is therefore the projection of a right angled triangle; and in the short distance $l'\ m'$ the tangent very nearly coincides with the plane of the spiral surface, hence the angle $l'\ a'\ m'$ will be a very close approximation to that formed between the chord of the curved joint in the face and the line $l'\ a'$; which is the angle represented by $u\ l\ a$, fig. 3, and that which it is required to find.

Fig. 3.



From o' where the axis intersects D E in plan draw $o'\ u'$ parallel to $l'\ m'$, meeting P P in u', produce $r\ o'$ to c'. In fig. 1 let $l\ a$ be the projection in elevation of the line $l'\ a'$; join $a\ c$ and produce it to u, making $l\ a : a\ u :: l'\ a' : a'\ u'$. Through u draw $u\ o$ at right angles to $a\ o$, meeting the vertical line B c produced, in o; and through l draw $l\ m$ at right angles to $a\ l$, meeting $o\ a$ produced, in m.

From the nature of the spiral surface it follows that $l\ a$ and $a\ u$ will be in the same straight line, and without going through the detail of each part of the construction, it will be seen that the triangle represented by $a'\ o'\ u'$ in plan, and $a\ o\ u$ in elevation, is a right angled triangle similar to, and in the same plane with the trangle $a'\ m'\ l'$, having the angle $o'\ a'\ u'$ equal the angle $l'\ a'\ m'$. Also that the side represented by $a\ o$ and $a'\ o'$ is the hypotheneuse, and is the line drawn from the point where the joint intersects the intrado to the point of convergence of the joints in the face; and that the side represented by $o\ u$ and $o'\ u'$, which is the perpendicular of the triangle $a\ u\ o$, is the hypotheneuse of another triangle whose perpendicular is $c'\ o'$, and the angle $c'\ o'\ u'$ equal to the angle of extrado. In the construction given in your last number, it will be seen that these are the two sides made use of to obtain the angle $u'\ a'\ o' = l'\ a'\ m'$, but in the formula it is more convenient to work with the base of the triangle $a'\ u'\ o'$, which is the line $a\ u$ in fig. 1, and represented by $a'\ u'$ in fig. 2, for when we have given

$\angle$ C D E $= \theta$ the angle of obliquity.
$\angle\ c'\ o'\ u' = \varphi$ the angle of extrado.
$\angle\ a\ c$ B $= \lambda$ the angle from the vertical,
and $a\ c = r$ the radius;

then drawing $a\ c$ at right angles to B c fig. 1,

(Fig. 1) $a\ c = r \sin. \lambda, = a'\ c'$ (fig. 2).
(Fig. 2) $o'\ c' = r \sin. \lambda, \cot. \theta.$
(Fig. 2) $o'\ u' = r \sin \lambda, \cot. \theta, \sec. \varphi =$ the perpendicular.
(Fig. 1) $o\ u = r \sin. \lambda, \cot. \theta, \tan \varphi.$
(Fig. 1) $u\ c = r \sin. \lambda, \cot. \theta, \tan. \varphi, \cot. \lambda = r, \cos. \lambda, \cot. \theta, \tan. \varphi.$
(Fig. 1) $a\ u = r + (r \cos. \lambda, \cot. \theta, \tan. \varphi) =$ the base.

$$\text{Therefore } \tan \angle\, u'\ a'\ o' = \frac{r \sin. \lambda, \cot. \theta, \sec. \varphi}{r + (r \cos. \lambda, \cot. \theta, \tan. \varphi)}$$

Separating the constant from the variable quantities, and calling

$r \cot. \theta, \sec. \varphi = a,$
and $r \cot. \theta, \tan. \varphi = b,$

$$\tan. \angle\, u'\ a'\ o' = \tan. \angle\, l'\ a'\ m' = \frac{a \sin. \lambda}{(b \cos. \lambda) + r}.$$

Hence if the arch be a semicircle on the square section, the expression for the angle $l'\ a'\ m'$ at the springing will be $\tan. \angle\, l'\ a'\ m' = \cot. \theta, \sec. \varphi.$

From the above may be proved the existence of the property discovered by Mr. Buck, namely, that the chords of all the joints in the face converge to one point below the axis; for $c\,o$ the distance of that point below the axis (fig. 1,) will be $o\,u \times$ cosec λ.

And $o\,u = r$ sin. λ, cot. θ, tan. φ.

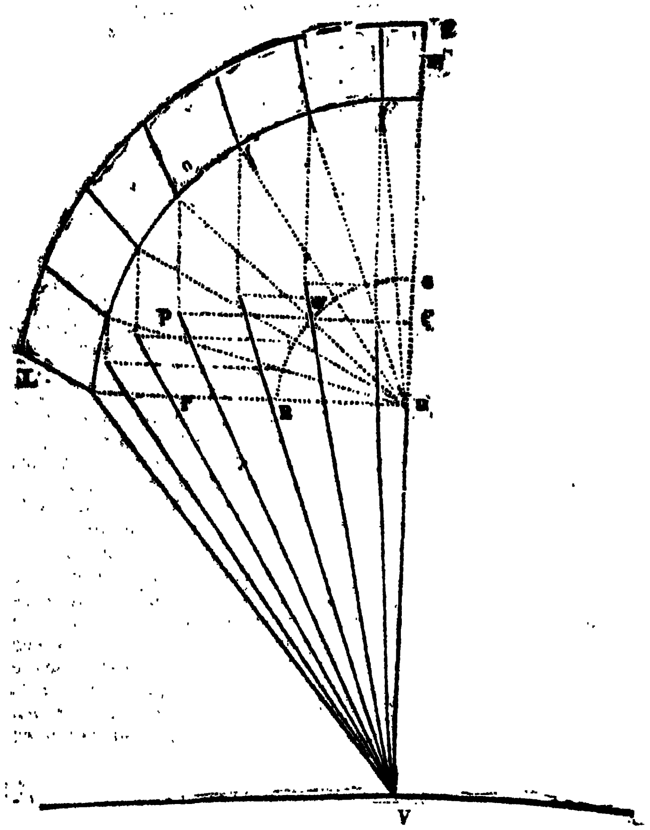
Therefore $c\,o = r$ sin. λ, cosec λ, cot. θ, tan. φ.

Whence the variable angle λ disappears, and $c\,o = r$, cot. θ, tan. φ.

This like the formula previously given for the angles, has reference to the line $m\,a$ (fig. 1,) and not to the true chord of the curved joint of the face; the approximation is however exceedingly close. If the angle of intrado be used instead of the angle of extrado, the results obtained by both formulæ apply to the *tangents* of the joint lines in the face, drawn from the points at which the joints intersect the intrado, and these results are *theoretically true*, though not available in the practical working of the case.

The formula tan. $\angle\, l'\,a'\,m' = \dfrac{a \text{ sin. } \lambda}{(b \cos. \angle) + r}$ leads to another construction for finding the angles between the joint lines in the face and soffit which possesses some advantages over that already mentioned.

Fi 4.



* The dotted line $n\,p$ should be produced to r, and V u produced to t—the dotted line $p\,t$ should be a full line.

Let L M (fig. 4) be the elevation of the face of an oblique arch, on a plane at right angles to the axis of the cylinder on which it is formed, $u\,s$ being the radius.

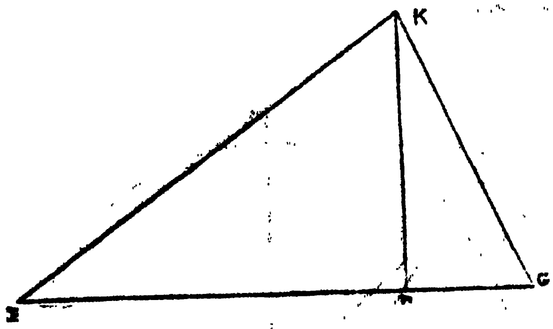
From the point K in the straight line K H, (fig. 5,) draw K F and K G, making the angle H K F equal the angle of obliquity of the arch, and the angle H K G the angle of extrado. Set off K G $= n\,u$ the radius, and through G draw G F at right angles to K H, intersecting K H and K F at H and F. Upon the vertical line M u produced (fig. 4,) set off $u\,v =$ F H, and from u with the distance H G describe the arc R W S. Then to find the angle formed out any joint n. Join $n\,u$ and through W where $n\,u$ intersects the arc R W s, draw $p\,t$ parallel to L u, and from n draw $n\,r$ parallel to M u, intersecting $p\,t$ in p. Join $p\,v$ and the angle $p\,v\,t$ is the required angle. For let F H $= r'$ and using the same letters for the angles as before.

$$\left.\begin{aligned} &\text{K H} = r' \text{ cot.} \\ &\text{K G} = r' \text{ cot. } \theta, \text{ sec. } \varphi. \\ &\text{H G} = r' \text{ cot. } \theta, \text{ tan. } \varphi. \end{aligned}\right\} \text{fig. 5.}$$

$$\left.\begin{aligned} &t\,u = r' \text{ cot. } \theta, \text{ tan. } \varphi, \text{ cos. } \angle. \\ &u\,v = r'. \\ &t\,v = r' + (r' \text{ cot. } \theta, \text{ tan. } \varphi, \text{ cos. } \angle.) \\ &\text{And } p\,t = r\,s = r', \text{ cot. } \theta, \text{ sec. } \varphi, \text{ sin } \angle. \end{aligned}\right\} \text{fig. 4.}$$

Hence the ratio of $p\,t$ to $t\,v$ is the same as a sin. $\angle$ is to (b cos. $\angle$) + r, and therefore the angle $p\,v\,t$ is the same as that obtained by the formula.

Fig. 5.



The angles for the remaining joints being found in the same manner, and the mould of curvature of the spiral line of the intrado applied at V, the curved bevels or templates for all the voussoirs on both sides of the arch are at once obtained as shown in the figure.

I am, Sir, your obedient servant,

W. H. Barlow.

Brereton, September 17, 1841.

N.B. Will you be so good as to make the following corrections in my last communication.

In Fig 1 the letter A is omitted at the intersection of the lines E K and D C.

Fig. 4 should be Fig. 3, and Fig. 3 should be Fig. 4.

In Fig. 3 the straight line S T R should be S′ T R′.

Page 292, line 3. For *draw G H* read *through E draw G H.*

THE NEW ROYAL EXCHANGE.

The contract of Messrs. Webb for the foundation of the new Royal Exchange was finished on Tuesday evening, and the Gresham Committee met on the 1st ult. to receive tenders for the second contract, which is for the completion of the whole of the edifice.

Fourteen of the principal builders of London had, as we formerly stated, been applied to, and it was also determined that each tender should contain two prices—the one being for executing the mason work with the best Portland stone; the other, the additional price for using magnesian limestone, similar to that introduced at the Houses of Lords and Commons.

The amount of the several tenders were as follows, September 1, 1841:—

Tenders.	Portland. £		Magnesian limestone. £
Thomas Jackson..........	115,900	..	124,700
Baker and Sons	122.765	..	127,300
Henry and John Lee	126.390	..	131,900
Samuel Grimsdell	126,762	..	133,348
Grissell and Peto	127,400	..	132,000
Piper and Co.............	128,700	..	131,100
John Jay	129,609	..	134,965
John and Joseph Little ..	129.800	..	134.380
Webb and Co.............	130,150	..	134,450
Joseph Bennett	131,500	..	133,500
Bridger	131,519	..	136,600
William Cubitt	132,200	..	135,700
Nicholas Winsland	134.219	..	136,620
H. Ward	135,500	..	138,500

The tender of Mr. Thomas Jackson was, of course, accepted. The whole of the works are to be completed by Midsummer, 1844.

The amount of the first tender for the foundations was £8124. See Journal, Vol. III. page 399.

Australian Steam Navigation.—Notwithstanding the wreck of one of the steamers, others have been sent out, and everything is now going on well.

Havannah.—A steamer has been started this month from Liverpool to Madeira, the West India Island and the Havannah.

SHANNON IMPROVEMENTS.

We have much pleasure in noticing the very spirited and energetic manner in which the Commissioners for the improvement of the navigation of the River Shannon, are carrying into effect the powers vested in them by Government—besides the various works in progress on the lower Shannon at Kilrush, Kilteery, Killisart, and Foyn's Island, and in our immediate vicinity at Illaneroon, Plassy, and Killalue. We learn that the same exertions are manifested to complete as soon as possible the numerous projected works on the middle Shannon, particularly at Meelick, Banagher, and Athlone, together with the important operation of dredging the bed of the river.

The principal feature of the improvements to be executed at Banagher, appears to be the erection of a new bridge over the Shannon, in place of the present old bridge, which measure has been found absolutely necessary, no less for the safety and accommodation of the public, than for the proper drainage of the country. The present bridge is built of rubble masonry, and consists of 17 arches of various dimensions, the piers of which occupy nearly one-half of the entire width of the river, the clear waterway being but 205 feet, whilst the total width of the piers is 244 feet. This structure is in a very dilapidated condition, and has lately shown numerous symptoms of its inefficiency as a means of communication between the King's County and Galway. It may however, be considered, (from its having been built in the reign of King John,) if not the oldest bridge over the Shannon, as at all events possessing an age which few other bridges can so satisfactorily trace, and is on that account, a very highly interesting work of antiquity. In its construction we find all that characterizes the early specimens of bridge architecture; the small arches for allowing the passage of the water, and, as before mentioned, unnecessarily wide piers, which have large angular projections not only to throw off the force of the current, but for the purpose of enabling passengers to retire into, to avoid carriages and horsemen when passing along its narrow roadway, the width between the parapets being only 12 feet.

The works of the foundation of the new bridge having been sufficiently advanced on the King's County side of the river, the first stone was laid by Colonel Jones, on Saturday, the 21st August; over which a brass plate was laid, bearing the following inscription:—

"SHANNON COMMISSION."

(Under the Act 2nd and 3rd Vic. Cap. 61.)

"By virtue of an Act passed in the second and third years of the reign of Her present Majesty Queen Victoria, the first entitled an Act for the improvement of the Navigation of the River Shannon, the following are the names of the Commissioners appointed for carrying the works into execution: Major-General Sir John Fox Burgoyne, R.E.K.C.B., K.T.S., &c. &c.; Lieut.-Colonel Harry David Jones, R.E., M.R.I.A., M. Inst. C.E.; Richard Griffith, Esq., C.E., F.R.S.E., M.R.I.A."

"This Bridge over the River Shannon at Banagher, was designed by Thomas Rhodes, Esq., C.E., M.R.I.A., M. Inst. C.E., the Commissioners' principal engineer, and the first stone laid on the 21st day of August, in the year of our Lord 1841.—Henry Buck, Esq., C.E., district engineer; Henry Renton, Esq., C.E. A. Inst. C.E., resident engineer; William Mackenzie, Esq., C.E., M. Inst. C.E., contractor.—Edward Hornsby, Secretary."

Having had an opportunity of inspecting the plans and other documents relative to the bridge, we are enabled to give some particulars which, perhaps, may be acceptable to our engineering readers. It is to consist of six semielliptical arches, of 60 feet span each, with a cast iron swivel bridge, of 46 feet span, to allow masted vessels and steamers an uninterrupted passage at all times. The following are the principal dimensions:—Span of stone arches each, 60 feet; rise of ditto, 16; thickness of abutment, 13; ditto of piers, 9; ditto of swivel bridge pier, 40; total length of bridge, including wings, 721; width of bridge, in clear of parapets, 24; ditto of carriageway, 16; ditto of each footpath, 4; thickness of arch stones at springing, 5; ditto crown, 2 feet 8 inches. The foundations will be all laid on a bed of strong gravel, at a level of about six feet below the bed of the river: the stone of which it is to be built is blue limestone, of a very fine quality, procured from a quarry recently opened adjacent to the works. The contract is stated to be about £23,600, and the whole of the works are expected to be completely finished in two years.

Mr. Faivelle is the contractor for building the much required pier at Kilrush, which is to extend 150 feet into the sea in a westerly direction, and there are 120 men now daily employed in the immediate neighbourhood quarrying stones for the work. The masonry embankment forming on the northern shore close to the present pier is very forward, and will be a great improvement.

Mr. Vignolles, C.E., son of the celebrated engineer of that name, is appointed resident engineer to superintend the construction of the piers or quays at Kilrush and Cahircon.

Mr. Sykes, of York, is declared contractor for building the pier of Cahercon, under the Shannon Navigation Commissioners, and the preparatory works will be commenced immediately.

The new pier, or quay, at Kilteery, between Glin and Loughill, in progress under the Shannon Navigation Commissioners, will be completed against winter, and admit of sailing vessels and steamers coming to there, in 21 feet of water, while the new road from Abbeyfeale, through the interior of the country, will render this a work of great public benefit to the farmer and trader—hitherto deprived of a market for their produce.—*Limerick Chronicle.*

Railway in the Brazils.—A railway has received the sanction of the Brazilian legislature and the support of the government, which is to run from Rio Janeiro to communicate with the provinces of St. Paulo and Matto Grosso. It has only one chain of hills to cross, the Serra de Parahyba.

STEAM NAVIGATION.

The Cairo.—A new steamer bearing this title made her first appearance on the Thames on Friday, 17th ult., and excited general attention. She was built by Messrs. Ditchburn and Mare, of Blackwall, for the Peninsular and Oriental Steam Navigation Company, for the navigation of the Nile, and is intended as a branch steamer to convey passengers and luggage to and from various places on the banks of that river. The Cairo is a remarkably elegant vessel, similar in appearance to those very fast and pretty steamers called the Watermen, running between London and Woolwich, and built by the same firm. The Cairo, however, is four feet longer and flat bottomed, to adapt her for the shallow waters of the Nile, her draught being only two feet. She is propelled by two engines of 16 horse power each, from the factory of Messrs. Penn and Son, of Greenwich. The cylinders are oscillating, and the machinery, which occupies a very small space, is precisely similar to that in the Watermen, and of the same dimensions. The cabins, fore and aft, are tastefully fitted up with bed places and other conveniences for passengers. The Cairo is an iron vessel, and divided into five compartments with water-tight bulkheads separating each, which adds much to the safety of the vessel. The engines and machinery occupy such a small space that 100 persons can be accommodated in the cabins, and there are two spacious stow-rooms for luggage only, between the engine-room and the fore cabin, and the engine-room and after-cabin. The Cairo made a trial voyage from the Blackwall pier to Gravesend and back, and with all the disadvantages attendant upon the working of new engines and machinery, she passed every thing on the river, the Star, a large Gravesend steamer, only excepted, and fully came up to the expectations of the builder and engineer. Mr. Ditchburn and Mr. Penn, jun., who entertained a select party of gentlemen connected with steam navigation on board, have guaranteed the average speed of the Cairo at 15 miles an hour; but for the Nile, a light draught of water is her greatest recommendation. Several other iron steamers, of similar dimensions, are to follow the Cairo to the Nile, and her design and appearance has been so much approved of, that the Watermen's Steam Packet Company intend to augment their fleet by five new vessels of the same size and machinery of the same power, to be in readiness by Easter Monday next. Messrs. Ditchburn and Messrs. Penn have taken the contracts.—*Times.*

Marine Engines.—It may be said that Great Britain is the manufactory for the whole world for marine engines; at one factory alone (Messrs. Maudslay and Field), there are at the present moment going through their various stages of manufacture, engines of 3600 horse power in the gross, viz. the *Devastation*, a government steamer with 400 horse power, fitted with double cylinders, now in the Woolwich basin just ready for action. The *Thames* and *Medway*, each with 400 horse power beam engines belonging to the West India Mail Company; the *Thames* is nearly ready; the *Herculaneum* (sister boat to the Mongebello) with 200 horse power, double cylinders, nearly completed for the Neapolitan government; and the *Memnon* with 400 horse power double cylinders for the East India Company. All the above engines are now being fitted on board of the several vessels—besides the above, in the same factory there are now in progress four pair of 150 horse, one pair of 100 horse for the Danish Government, and a pair of 100 horse for the admiralty all with double cylinders, also two pair of 50 *annular* cylinder engines on Mr. Joseph Maudslay's last patent. In another place we have noticed engines for Egypt and the United States.

The Satellite.—A beautiful iron vessel built by Messrs. Ditchburn and Mair has been running the last two months between the Adelphi and Gravesend with great speed and regularity. She draws but little water, and frequently steams the distance from Blackwall and Gravesend in about an hour; she has a pair of 25 horse *steeple* engines arranged expressly for her, which are a beautiful specimen of Messrs. Miller, Ravenhill and Co.'s workmanship, they occupy a very small space in the vessel and are fitted with expansive gear worked with great simplicity.

Steam Towing.—We learn that during the present fruit season a steamer will tow vessels between Malaga and Gibraltar. It is to be hoped that this system of towing in the sea will be extended.

The Chili.—We regret to learn that this steamer has been wrecked on the coast of the same name.

FOREIGN INTELLIGENCE.

The Mosaic Pavement at Salzburg.—Munich, Sept. 7.—Private accounts from Salzburg state that it is intended to remove the lately discovered Roman mosaics from their present position, and lay them down in another situation, where they may be protected from the influence of the weather. It is said that the place fixed on is the site of Mozart's monument. Besides the large mosaic pavement, the design of which consists only of architectural ornaments and foliage, two smaller pieces were discovered, which are equally devoid of pictorial representation. There are likewise considerable remains of the walls of the chamber to which these mosaics belonged. The paintings on these are similar to those found at Pompeii, consisting of flowers and tendrils of vines on a red ground. The mosaics, as well as the paintings, are evidently of the third or fourth century after Christ. One very striking peculiarity in the smaller mosaics is the frequent introduction of the sign of the cross, which it is scarcely possible to regard as a mere accidental ornament. At the depth of half a foot below the large mosaic pavement, is another of finer workmanship, which, as it is necessarily the more ancient, promises to be an object of still greater interest. The proprietor of the house must have had some motive in thus covering over the old pavement and raising another. If once the upper pavement were removed, there would be [illegible] in uncovering the second.—*Allgemeine Zeitung.*

St. Petersburg, August 26.—800 workmen are now daily employed in rebuilding the Imperial palace in the Kremlin at Moscow, which was pulled down four years ago. The new building is made fire-proof, the very rafters being of iron, and no wood being employed except for the floors. This palace is to be heated by means of 250 metal pipes communicating with every part of the building, and proceeding from a furnace contained in the vaults below. The ornamental gilding alone costs 800,000 rubles.

The great hall of St. George of the winter palace, which had just been rebuilt, had given way, and all the splendid Italian paintings and vases which it contained been destroyed.—The loss is estimated at several millions of francs. No life was lost; and the remainder of the palace was intact. On the day before the accident a chapter of the Order of St. George was held in the hall which has fallen.

Venice.—A bridge is about to be constructed at Venice, intended to unite that city to the Continent, and to connect it with the railroad of Milan. The management of this gigantic undertaking has been conceded to the engineer, Antoine Busetto Pitich; the average expense is estimated at 4,830,000 livres Austrian. The bridge will also contain an aqueduct intended to supply the town with fresh water, which has hitherto been supplied in boats from the Continent; Venice being unprovided with wells and fountains, and having but very few cisterns.

The Improvement of the Seine.—A commission has been appointed by the Prefect of the Seine, to take into consideration a project for improving the navigation of the river within and below Paris. Part of the project consists in establishing this navigation on the left branch, running along one side of the Cité. Another plan attached to it is the construction on the centre of the Pont Neuf of a vast building, from which eight turbines, of the force of 4000 horse power,(?) would throw immense quantities of water into every quarter of Paris.

Russia.—A joint-stock company in England has obtained the Emperor's permission to make an iron railway from Moscow to St. Petersburgh, and will begin its operations perhaps this autumn, but certainly in the spring. Five years are allowed to complete the whole line, which will be 33 miles longer than the common road between Moscow and St. Petersburgh, because it is to pass through to Bybinsk, in the government of Yaroslaw, on the right bank of the Volga, because that town carries on the most extensive corn trade with St. Petersburgh. All the vessels laden with the produce of the south, which comes up the Volga to the north, must stop here.—*Hamburgh papers, Sept. 10.*

The Rhein and Mosel Zeitung of Sept. 4 states. that in the course of the operations in the Cathedral of Cologne for the restoration of the pictures of the Saviour and the Apostles Peter and John, the workmen have brought to light several colossal figures which have been obliterated with whitewash during the last century. It is to be hoped that these figures will be restored along with the others to their original state. The same journal mentions that the two pictures which had been wantonly injured at the exhibition in Cologne have been again hung up in their places, after having been removed for the purpose of repairing them. In spite of every inquiry, the person who committed the malicious act has not yet been discovered, nor is it possible to assign any imaginable ground for so wanton an outrage.

MISCELLANEA.

The Sun Fire-office Building.—The dispute between the city authorities and the Sun Fire-office, is at last terminated by the consent of the latter body to set back their building to the act of Parliament line, and to round the corner at the south-east of Bartholomew-lane. The Commissioners of Sewers will pay, as the value of the land thus appropriated to the public, such a sum as may be determined upon by Mr. Cockerell, the surveyor of the Sun Fire-office, and some surveyor to be appointed by themselves. The directors of the Sun Fire-office have, in the opinion of the citizens, acted most unwillingly and ungraciously, and it would have been much more creditable to these directors to have conceded to general convenience, what was never equitably theirs, than, by persisting in forming this projection, to have compelled the Commissioners of Sewers to appropriate public monies to an improvement in which the Sun Fire-office was really as much interested as the public themselves.—*Times.*

New Mode of Rating the Gas and Water Companies.—Some of the parishes in the eastern districts of the metropolis have lately been making a valuation survey of the length and bores of the various mains and branch services belonging to the Water Companies in their respective parishes, as also the length of the gas-pipes laid down, and all property belonging to them, for the purpose of rating them on a fair and equitable per centage, in the place of allowing the companies to compound for them, by the payment of a stipulated annual sum as heretofore, and which composition has been found in reality to be much beneath their actual value. The companies' profits, it is well known, being very considerable, their property has not been rated in a fair proportion to the general property of the parish. By the adoption of rating the companies after the survey, the parishes will derive a great annual increase of revenue, which will contribute much to relieve the parishioners in general, by adding to the parochial resources. The example is about to be followed by other parishes in the southern districts, who are making surveys for the same purpose, where the source of revenue, increased by rating, will be much more considerable, in consequence of the immense quantity of water and gas-pipes laid down in the southern districts by several companies in rivalry of each other.—*Times.*

Improved Locomotive.—Messrs. Coulthard, of Gateshead, engineers, have just completed a powerful locomotive engine, including all the modern improvements, with also, in one respect, a novelty in construction of great practical advantage. This consists in the rejection of what we may call the "cinder-chamber," so that the bars are exposed to the external atmosphere, and the ashes fall directly upon the ground. Thus, the bars being presented to the cold air on the outside, they do not waste away with that rapidity which is consequent upon the ordinary construction, and considerable economy is the result. The engine being built more for power than for speed, the works are placed chiefly on the outside, and are of peculiarly easy access for purposes of repair. Trial was made of her powers on Thursday week, in the presence of Mr Wood, under whose superintendence she was built, and other gentlemen, who were much gratified by her performances; and after remaining for experiment on the Brandling Junction Railway a few days from this time, she will be removed to the Clarence line, to commence her labours in good earnest.—*Tyne Mercury.*

The Strike at the New Houses of Parliament.—The strike of the two hundred masons is likely to be productive of much injury to the working men, as they could not have chosen a worse plea on which to strike, while they have put themselves in direct contact with government. All combinations are bad, and particularly where they are employed to repress industry for the benefit of idleness. Nothing can be more infamous than a system which fines men for working faster than their fellows. The masters will gain by this imprudence.

Sir William Burnett's patent process for the preservation of timber, canvass &c. is gaining ground with the public; it has already been adopted by the government authorities at the dock yards. For the service of the Portsmouth Dock Yard, there is now being made at Messrs. Fairbairn's, Mill Wall, a large iron tank, 51 feet long and 6 feet diameter, with air and force pumps for the purpose of impregnating timber and canvass with Sir William's solution—it is also to be applied for the preservation of upwards of 6000 yards of felt, and the deal casing to be used for clothing the steam boilers of H. M. War steamer the *Growler*, now having her engines put on board at Messrs. Seawards manufactory at Limehouse.

Hoax by a Bank Clerk.—Last month we transferred into our columns an extract from the *Literary Gazette*, giving a short account of a newly-discovered method of propulsion, by which a common garden or invalid chair could be propelled along a common road by a galvanic power at the rate of 40 miles an hour; and it was further stated that the young man who had discovered this new power daily travelled in his chair from St. Alban's to the Bank of England in half an hour—a distance of 22 miles! Great curiosity was naturally excited by the supposed discovery, and the young man, who is a Bank clerk, was questioned concerning it, both by the governor of the Bank, and also by Mr. Smee, the cashier, &c. He was invited by the latter, and by several other persons, to display the powers of his new machine, but made repeated excuses for delay; he first excused himself on the score of illness, and on being again pressed to exhibit the machine, he stated that he had driven it accidentally against a post, and shattered it to pieces. Upon being, however, more closely questioned, he at last confessed that the whole story was a hoax, and that no such machine had ever existed, save in the fertile imagination of the supposed inventor. This *denouement* was only made known on Thursday, and it has created a great sensation in the Bank of England. The motive of the youth for the above hoax cannot be accounted for. We are informed, however, that some such galvanic power does exist,(?) but that the expense is too great to allow of its being made use of.—*Times, Aug.* 28.

Projected Light on the Goodwin Sands.—The Lords of the Admiralty and the Board of the Trinity-house have finally arranged with Mr. W. Bush, the engineer, that the cast-iron caisson, which he has now nearly completed at Deal, shall on Wednesday, the 15th inst., be floated to its place on the north-east end of the Goodwin Sands. It will be remembered some weeks ago we noticed the progress of this undertaking, which is now about to be sunk and firmly fixed to the chalk rock which Mr. Bush calculates on finding about 30 feet below the surface of the sand. The caisson will then form a base upon which a lofty column of stone will be raised, surmounted with a light, and that from its position and general usefulness to all maritime counties, it will be called "The Light of all Nations," which will be inscribed on the column. This new Goodwin light is not only designed as a beacon to warn the mariner off these sands, which have been so fatal, but is also intended as a guide from the North Sea, through a swashway, hitherto, from its danger, impracticable. This channel is about half a mile wide, and leads into a capacious bay within the Goodwin, having from 30 to 40 feet water, and being sheltered from every quarter, ships will there ride in safety. A very large party are going out on the 15th to view the floating of the caisson, and the Government steamers are ordered to be in readiness. It is expected that his Grace the Duke of Wellington, who takes a lively interest in the undertaking, will be present on the occasion.—*Times, Sep.* 6.

Newly Recovered Land.—Since the opening of the new cut from Eau Brink to Lynn, which took place about 20 years ago, the old channel, which was very wide and spacious, by which the water of the Ouse and its tributary streams were formerly conveyed to Lynn, has been gradually silting up, and much of it has now become firm land, producing rich and flourishing herbage. A few days since a portion of this newly recovered land (containing about 900 acres), which is now embanked and fenced with live quickset fences, and divided into convenient pieces for occupation, was let by auction, at the Globe Inn, Lynn, and the annual rental obtained for it averages nearly 3*l.* per acre. Calculating upon this ratio, were an embankment of the Wash to take place, the annual value of the land which would be obtained by that undertaking we might reasonably estimate at not less than £500,000. At the last quarterly meeting of the Lynn town-council, Mr. F. Lane laid upon the table a copy of a memorial presented to the Commissioners of Woods and Forests, which memorial referred to the inclosure of the Great Level of the Wash, and was accompanied with a letter, stating that the application to Parliament upon that subject was intended to be renewed in the next session. —*Norfolk Times.*

London Bridge.—This bridge is to be closed for the purpose of repaving the road, which is to be done with Aberdeen Granite, not exceeding three inches in width, to be laid in parallel courses.

Windsor Home Park.—Great improvements are going on by order of Her Majesty. A very neat iron bridge has been erected over the Datchet road which has been covered with the Seyssel Asphalte. Other works in Asphalte have also been executed at the castle.

LIST OF NEW PATENTS.

GRANTED IN ENGLAND FROM 24TH AUGUST, TO 23RD SEPTEMBER, 1841.

Six Months allowed for Enrolment.

RICHARD WHITAKER, of Cambridge, machinist, for "*improvements in cutting the edges of books, and paper for other purposes; and in impressing ornaments, letters, and figures on the binding of books and on other surfaces.*" —Sealed September 4.

THEOPHILE ANTOINE WILLHELME COUNT OF HOMPESCH, of Mivart's Hotel, Brook-street, Middlesex, for "*improvements in obtaining oils and other products from bituminous matters, and in purifying or rectifying oils obtained from such matters.*"—September 4.

JOHN BOOT, of Quandron, Leicester, lace glove manufacturer, and JOHN KING, of Henor, lace maker, for "*certain improvements in machinery or apparatus for manufacturing or producing figured or ornamented fabrics in warp and bobbin-net lace machines.*"—September 4.

JOHN GRAFTON, of Cambridge, civil engineer, for "*an improved method of manufacturing gas.*"—September 4; two months.

MICHAEL COUPLAND, of Pond-yard, Southwark, millwright and engineer, for "*improvements in furnaces.*"—September 4.

GEORGE WILDES, of Coleman-street, merchant, for "*improvements in the manufacture of white lead.*" (Being a communication.)—September 4.

WILLIAM HILL DARKER, senior, and WILLIAM HILL DARKER, junior, both of Lambeth, engineers, and WILLIAM WOOD, of Wilton, carpet manufacturer, for "*certain improvements in looms for weaving.*"—September 4.

LOUIS LACHENAL, of Titchfield-street, Soho, mechanic, and ANTOINE VIEYRES, of No. 40, Pall-mall, watch-maker, for "*improvements in machinery for cutting cork.*"—September 4.

JOHN JUKES, of Lewisham, gentleman, for "*improvements in furnaces or fire-places.*"—September 6.

PIERRE PELLETAN, of St. Paul's Church-yard, professor of medicine, for "*improvements in propelling fluids and vessels.*"—September 6.

JOSEPH DREW, the younger, of Saint Peter's Port, for "*an improved method of cutting and rolling lozenges, and also of cutting gun-wads, wafers, and all other similar substances, by means of a certain machine designed by him, and constructed by divers metals and woods.*"—September 6.

LUKE HEBERT, of No. 12, Staple's-inn, London, for "*certain improvements in apparatus and metals used in the manufacture of gas for illumination; also improvements in the apparatus for burning the same.*" (Being a communication.)—September 8.

RICHARD ELSE, of Gray's-inn, Esq., for "*certain improvements in machinery or apparatus for forcing and raising water and other fluids.*"—September 8.

WILLIAM FAIRBAIRN, of Millwall, Poplar, engineer, for "*certain improvements in the construction and arrangement of steam engines.*"—September 8.

JOSEPH COOKE GRANT, of Stamford, ironmonger and agricultural implement maker, for "*improvements in horse rakes and hoes.*"—September 8.

NATHANIEL CARD, of Manchester, candle-wick-maker, for "*certain improvements in the manufacture of wicks for candles, lamps, or other similar purposes, and in the apparatus connected therewith.*"—September 8.

JAMES THORBURN, of Manchester, machinist, for "*certain improvements in machinery for producing knitted fabrics.*"—September 8.

MILES BERRY, of Chancery-lane, civil engineer, for "*a new or improved method or means of, and apparatus for, cleansing typographical characters or forms of type, after being used in printing.*" (Being a communication.)—September 8.

OGLETHORPE WAKELIN BARRATT, of Birmingham, metal-gilder, for "*certain improvements in the precipitation or deposition of metals.*"—September 8.

JOSEPH GARNETT, of Haslingden, dyer, and JOHN MASON, of Rochdale, machine maker, for "*certain improvements in machinery or apparatus employed in the manufacture of yarns and cloth, and are also in possession of certain improvements applicable to the same.*" (Being partly a communication.)—September 8.

EDWARD LOOS DE SCHELLESTADT, engineer and chemist, and [illegible] STERLINGUE, tanner, of Regent's-square, in the county of Middlesex, for "*certain new or improved machinery or apparatus and process for tanning skins or hides, and preparing or operating upon vegetable and other substances.*" —September 8.

GEORGE MANNERING, of Dover, plumber, and HENRY HARRISON, of Ashford, plumber, for "*certain improvements in the means of raising water and other liquids.*"—September 8.

ALPHONSE RENE LE MIRE DE NORMANDY, of Redcross-square, Cripple-gate, [illegible] "[illegible]."—September 8.

WILLIAM CROSSKILL, of Beverley, iron-founder and engineer, for "*improvements in machinery for rolling and crushing land, and in machinery to be used in the culture of land.*"—September 9.

WILLIAM HICKLING BENNETT, of Ravensbourne Wood-mills, Deptford, gentleman, for "*improvements in machinery for cutting wood, and in apparatus connected therewith, part of which may be applied to other purposes.*" —September 9.

CHARLES LOUIS STANISLAS BARON HEURTELOUP, of Albany-street, Regent's-park, for "*an improved manufacture of continuous priming for, and improved mechanism for the application of the same to, certain descriptions of fire-arms.*"—September 9.

CONRAD FREDERICK BRUCKMEYER, of Golden-terrace, Barnsbury-road, Islington, merchant, for "*certain improvements in obtaining and applying motive power by means of winds and waves, for propelling vessels on water, and driving other machinery.*"—September 17.

WILLIAM NEWTON, of Chancery-lane, civil engineer, for "*improved machinery for manufacturing felts or felted cloths.*"—September 20.

JOSEPH HULME, of Manchester, engineer, for "*certain improvements in machinery or apparatus for grinding, sharpening, or setting the teeth of cards, or other similar apparatus employed for carding or operating upon cotton, wool, or other fibrous substances.*"—September 20.

THOMAS HUCKVALE, of Over Norton, Oxford, farmer, for "*improvements in horse-hoes, and in apparatus for treating and dressing turnips, to preserve them from insects, and promote their growth.*"—September 20.

ALFRED ELAM, of Huddersfield, surgical instrument maker, for "*improvements in apparatus for instruments for the relief and cure of procedencia and prolapsus uteri.*"—September 20.

LUKE HEBERT, of Birmingham, for "*improvements in machinery for fulling woollen cloth.*" (Being a communication.)—September 20.

WILLIAM CHARLTON FORSTER, of Bartholomew Close, gentleman, for "*a material, or compound of material, not hitherto so used for preventing damp rising in walls, and for freeing walls from damp, which material, or compound of material, can be applied to other purposes.*"—September 20.

FRANCOIS MARIE AGATHE DEZ MAUREL, of Newington Terrace, Surrey, for "*an improved buckle.*" (Being a communication.)—September 20.

GEORGE SHILLBEER, of Milton-street, Euston-square, carriage builder, for "*improvements in the construction of hearses, mourning and other carriages.*" —September 20.

WILLIAM BUSH, of Deptford, engineer, for "*improvements in the means of, and in the apparatus for, building and working under water.*"—September 21.

COMTE MELANO DE CALCINA, of Nassau-street, Soho, for "*improvements in paving or covering roads, and other ways, or surfaces.*"—September 21.

EDWARD EMANUEL PERKINS, of Weston Hill, Norwood, gentleman, for "*improvements in the manufacture of soap.*"—September 21.

JOHN DUNCAN, of Great George-street, Westminster, gentleman, for "*improvements in machinery for driving piles.*"—September 21.

HENRY BESSEMER, of Baxted House, Saint Pancras, engineer, and CHARLES LOUIS SCHONBERG, of Sidmouth Place, Gray's Inn Lane Road, artist, for "*improvements in the manufacture of certain glass.*"—September 23.

GEORGE SCOTT, of Louth, miller, for "*certain improvements in flour mills.*" —September 23.

JAMES WHITELAW, engineer, of Glasgow, and JAMES STIRRAT, manufacturer, of Paisley, Renfrew, for "*improvements in rotary machines to be worked by water.*"—September 23.

TO CORRESPONDENTS.

Mr. Pilbrow.—*We shall be happy to lay before our readers any new facts he may bring forward in support of his peculiar form of Engine, and when he has got the steam up in the 50 horse engine now constructing on his principle, we shall feel much pleasure in recording the results.*

Mr. Barret and Mr. Brooks.—*We have been again called to account by these two gentlemen, for not publishing their communications; we can assure them that it is our desire to accommodate all our correspondents if possible, but on account of the numerous articles connected with the profession which demand immediate attention, we are obliged to defer controversial articles; we will however endeavour next month to accommodate both Mr. Barret and Mr. Brooks.*

Probably after three years more practice F. will say that we have been merciful.

Books received which must stand over for notice until next month—Elements of Perspective Drawing; Report on Boucherie's Process of Preserving Wood; Dawson's Outline of a Method of Model Mapping; A Letter to the Shareholders of the Bristol and Exeter Railway, by W. Gravatt, C.E., F.R.S.; this letter discloses some suspicious circumstances, which we hope before our next publication appears, the parties concerned will be able to clear up.

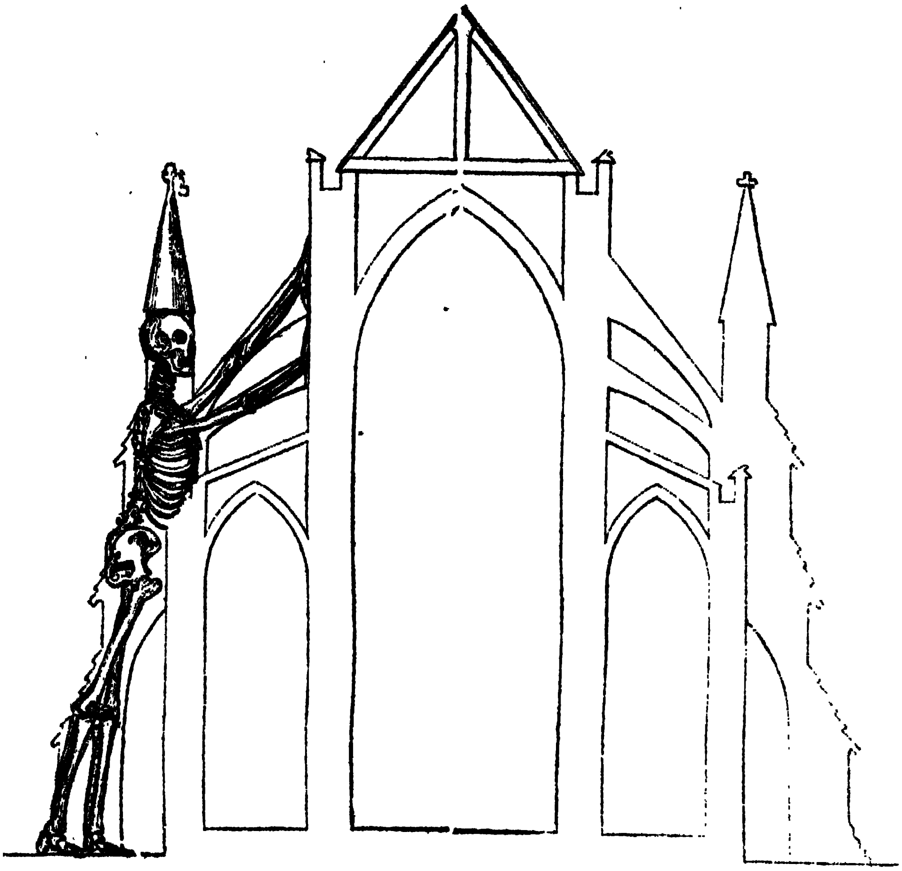
We regret that we have not been able to find room for a very valuable report on the Improvement of Lough Erne, by Mr. Rhodes, E.C.

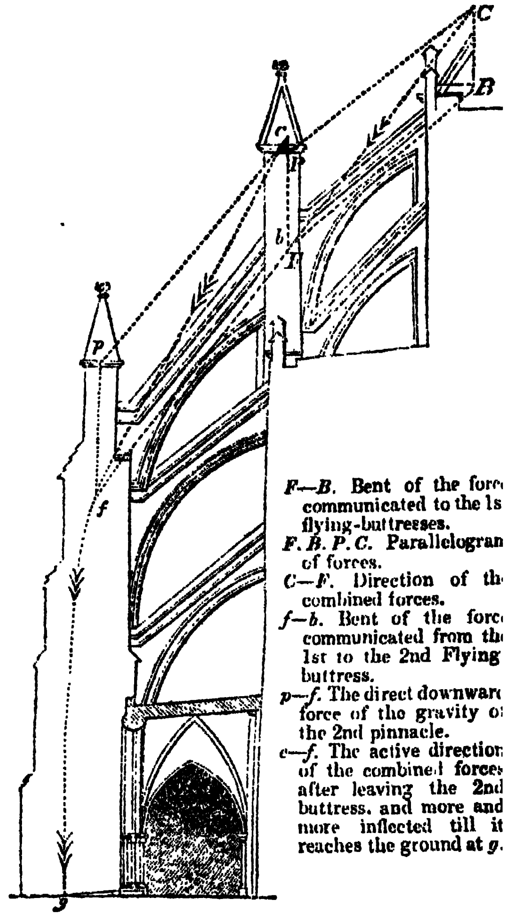
Communications are requested to be addressed to "The Editor of the Civil Engineer and Architect's Journal," No. 11, *Parliament Street, Westminster.*

Books for Review must be sent early in the month, communications on or before the 20th (if with drawings, earlier), and advertisements on or before the 25th instant.

Vols. I, II, and III, may be had, bound in cloth, price [illegible] each Volume.

ON BUTTRESSES, PINNACLES, &c.





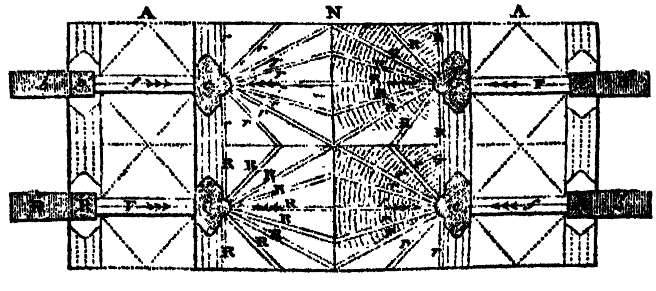
F—B. Bent of the forc communicated to the ls flying-buttresses.
F. B. P. C. Parallelogran of forces.
C—F. Direction of th combined forces.
f—b. Bent of the forc communicated from th 1st to the 2nd Flying buttress.
p—f. The direct downwar force of the gravity o the 2nd pinnacle.
c—f. The active directior of the combined forces after leaving the 2nd buttress, and more and more inflected till it reaches the ground at *g*.

ON BUTTRESSES, PINNACLES, &c.

By Alfred Bartholomew, Architect.*

Were it the author's wish to prove by one example more striking than any other, the falling off of science in the absolute practice of architecture, in these times of pretended superiority, in which the ill-taught practitioner who wishes to pursue the integrity of his art, is obliged, after he is turned adrift by his master, to re-educate himself as far as he is able, by picking up whatever scraps of scientific information may fall in his way, instead of receiving from his master at once the full depth of skill which the free-masons for centuries handed down from father to son, from master to pupil, without diminution and without reserve,—he would fearlessly instance the most singular advancement which the mid-eval architects seem, by nothing short of inspiration, to have made in the most delicate acquaintance with *Architectural Dynamics*; a knowledge which taught them at once to unite in their abutments, strength with economy, use with beauty: while in our ignorance we fancy that strength and economy are enemies of each other and that use and beauty are of necessity opposite qualities. This refined intelligence taught them to render every necessary part of their constructions such exquisite ornaments, that the ignorant modern looking at them, without knowing their use, fancies them to be merely ornamental.

They first began in their vaultings with reducing the lateral thrust of the work to the smallest limits, by cutting out all the otherwise more level and hazardous parts of the vaulting, so that what remained scarcely left its perpendicular bearing upon the walls: they next greatly reduced further the weight of the vaulting, by forming it of small stone ribs, with a mere thin cuticle of lighter materials in short and narrow panels between the ribs; and whereas in our modern brick vaultings, the groin-points are weak by their bond, and are still weaker from the soft and inferior nature of the bricks of which they are composed (vulgarly termed "*cutters*," and wholly unfit for the purposes of any *good* work), and we know scarcely any thing of the *dynamics* of such a vault,—the mid-eval builder put all the strength in the ribs, strutted his ribs across as he deemed necessary, and made every strut a beauty, conducted the active force down those ribs as easily as water is conducted down a pipe, and then, instead of leaving the active force within each rib to expend itself in committing unknown and unrestrained damage to the walls of the fabric, he united their force in one point so that he could deal with it as an active power well ascertained; then knowing by the laws of the resolution of forces the way in which the united thrust of the ribs would move, he counter-acted by the



N, nave. A, A, aisles. R, R, &c., ribs of the vaulting, the several thrusts of which all uniting at the centre C; the dynamic action is confined to one point tending to move from C to F. F, flying-buttress, falling against the point C, in the direction exactly suited for opposing the united thrust of the vaulting-ribs. B, wall-buttress from which the flying-buttress springs. P, pinnacle. The small letters indicate the repetition of sets of the same parts belonging to other divisions of the vaulting.

* We have through the kind permission of the author, taken this paper from a work recently published by him, entitled, "Specifications for Practical Architecture; preceded by an Essay on the decline of excellence in the Structure and in the Science of Modern English Buildings."

smallest possible quantity of materials set in the form of flying-buttresses, pinnacles, and wall-buttresses, that force which unrestrained might have endangered the walls. Thus by making use of only a small quantity of materials, every particle of which was brought into active service, he was enabled to carve ornament and enrich every part of his fabric out of those funds which we ignorant moderns expend in raising coarse masses which perform no duty, or ill-directed either waste much of their weight and strength, or else employ it in rending and dilapidating the fabric.

The author comes now to a department of the dynamic knowledge of the Gothic architects, which, as he believes it outstrips in combination of skill and beauty all other efforts of the architectural practitioner, ancient or modern, affords him matter of surprise, that as far as he knows or remembers, it has not been noticed by any previous writer.

The manner in which the Gothic architects conducted the active force of a vault to one place, and then with practical certainty counter-abutted that force by a small quantity of materials placed exactly in the situation proper for the purpose, has just been shown; it is now proposed to show the wonderful manner in which the flying-buttresses, the wall-buttresses from which they spring, and the surmounting pinnacles, are together disposed so as with the most delicate union of the extreme of beauty, to unite the most wonderful economy and such a knowledge of mechanics as will in vain be sought for in any other description of buildings.

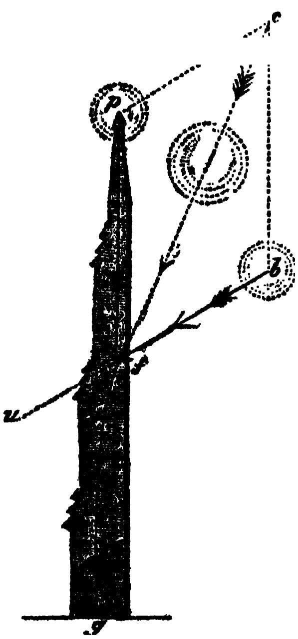
Having found out exactly the precise place where the active force of the vaulting was pressing against the wall, they distended the *flying-buttresses* or *arc-boutant* widely at that part, in the same manner as a modern carpenter, in *temporary-shoring*, places a board flat against a dangerous wall; they then gradually concentrated this distention of the wall-thrust into one point, where the flying-buttress joins the wall buttress; thus they concentrated at the head of the wall-buttress, all the active force communicated by the vaulting, in the same manner as in wrestling all the force received by the arms becomes concentrated in the spine, pressing its vertebræ closely together; but then as the operation of this force, would have required the wall-buttress to be made sprawling out to a vast distance from the wall, in order to prevent the active power from throwing it over, they change the course of the active force, simply by running up the head of the wall-buttress in the form of a pinnacle, which, having only a direct downward gravity, by the *resolution of forces*, so changed the course of the active force, that it could be confined within the body of a buttress of comparatively moderate dimensions,—the downwardly-increasing gravity of the wall-buttress in fact mingling with the force communicated to it, curved the direction of the force more and more inwards, till it was eventually re-diffused horizontally over the broad foundation of the buttress, and was from thence communicated to the earth itself. Thus

f—b. Bent of the force communicated to the flying-buttress by the *drift* of the vaulting, which force would proceed unrestrained to *u*, if the pinnacle were removed, and would consequently drive over the wall-buttress in that direction.

p—f. The direct downward force of the gravity of the pinnacle.

—f. The active direction of the two combined forces above-stated, more and more restrained in its downward course, within the body of the wall-buttress, till it reaches the ground at *g*.

b, p, e. Parallelogram of forces.



pinnacles, which are vulgarly considered merely as ornaments, became the most refined instruments in the economy and security of ecclesiastical and other buildings, and like the position of the human head, had a most material influence upon the stiffness and activity of the whole frame. With this knowledge, it was, that the Gothic architects proportioned the weight and size of their pinnacles, and when we see them assuming an extraordinary altitude, as at Worcester Cathedral, it is not from idle, wild, or luxuriant caprice, but because extraordinary means were required in order to change suddenly the course of an active power, which would otherwise have expended itself beyond the body of the abutment, and by displacing it, have brought to ruin the whole work.*

They did not always stop here, for knowing that there was a portion of the wall-buttress near the ground and adjoining to the side aisles, which received no thrust, and lay as it were dead, this they cut out altogether, as at Gloucester Cathedral, some of our English Chapter-houses, Westminster-hall, and some of the Continental Cathedrals which have chapels set between their wall-buttresses;† so that in fact, the whole form, position, and management of the counter-abutments of Gothic vaultings, were like those of a human skeleton, placed in a leaning posture, with the bones of the legs away from the base, those of the hands and arms pressing against the moving part of the vault, with the skull erect to confirm and steady the spine, and the whole strengthened by sufficient flesh and muscle.

That the true mechanical office of the pinnacles of pointed architecture is as stated above, appeared to the author to be so evident, that it at once struck him after coming to this knowledge, that the double set of flying buttresses on the south side of Westminster Abbey, must be respectively inclined, so as to receive within their solid substance the pressure of the vaulting; and that on account of the operation of the two sets of pinnacles, the lower flying-buttresses must be set more uprightly than the upper ones; this upon examination proved to be the case, showing that if the original builders were not fully versed in the subject (which may be greatly doubted), Wren, who restored these buttresses, was so, and probably by his great scientific knowledge, was enabled to adjust them more accurately to their proper positions. The great masters who had to do with this fabric, could not avoid the great extra consumption of materials which arose from removing the great buttresses away from the wall out into the cloister-green, in order to leave room for the north avenue of the cloister; but having a difficult task to perform, they performed it with admirable skill, and knowledge greater than is exhibited in many of the Continental Cathedrals, some of which have two sets of buttresses in order to admit side chapels.

With what humility should we look upon our modern use of buttresses, pinnacles and abutments, which we pretend are the results of a far outstripping science, and of an improved taste,—while men whom we have been in the habit of calling barbarians, have in a dark age (more enlightened in many things than the best ages of Greece and Rome) at once mingled in their works, poetry, economy, taste, strength, and invention.

Geometrical Survey.—The officers of the engineers appointed to conduct the survey of the island have been for the last six weeks stationed upon the top of Ben Volich, a high and peaked mountain in Rannoch, east of Lochgarry. They had spent the greater part of the summer on Schihallion, but the severity of the weather of late has both both impeded their operations and rendered the station very uncomfortable. For the last fortnight the snow has been lying some inches deep around their very superficial temporary dwelling, and the carriage of fuel from the surrounding districts is at once expensive and precarious. The view from this moutain, as well as from Schihallion, is very extensive from their commanding altitude, and enables the engineers to take a very wide observation.—*Scotch Paper.*

* Rondelet in his "*Traité Théorique et Pratique de l'Art de Bâtir*," shows that he had sagacity enough to find out the beauty of the whole management of the dome of St. Paul's, and that he saw plainly the consolidating effect which the weight of the covering of the dome has upon the hollow cone; but it is singular that this sagacity did not preserve him from in some sort deprecating the oblique meeting of the cone with its supporting piers; he did not perceive, that besides the enormous collection of surrounding abutments which the great cone possesses, the perpendicular extension of the external peristylium above the foot of the cone, acts so as by the resolution of forces to materially change the direction of any expanding thrust which the base of the cone may possess, and to confine it strictly within the bodies of the first set of piers.

† Mr Savage, at the New Chelsea Church, has omitted the nactive parts of the wall-buttresses in order to admit a *free passage* in the dry areas which surround the basement-story of the edifice; but he has not changed the *drift* in the flying-buttresses by placing pinnacles over the wall-buttresses; allowing the present wall-buttresses of the church to be sufficient, the [illegible] combustible ceilings over the galleries of the church might be exchanged for groined roofs of stone, and the addition of pinnacles would still [illegible] drift within the present wall-buttresses, notwithstanding the added drift of the new side vaults.

ON CLOTHING OF STEAM BOILERS.

Report upon the advantages to be derived from Clothing Steam Boilers, Pipes, Cylinders, &c., with the Patent Felt, manufactured by Messrs. Borradaile, Whiting, and Company.

By Thos. Wicksteed, Mem. Inst. Civil Eng., Hon. Mem. Roy. Cornish Polytech. Soc., &c. &c.

[We feel much pleasure in being able through the kindness of Messrs. Borradaile and Co., to give to our readers the following very valuable report on Clothing of Steam Boilers and Cylinders, and which we are sure will be perused with much interest. We must here observe that too much praise cannot be given to those gentlemen for the spirited manner they have had the experiments made, which could not have been done excepting at a very large outlay. We think after a careful study of this report by those who have a steam engine not already clothed, they will hesitate no longer in adopting that very essential requisite, which we are sorry to say has been, heretofore, most shamefully neglected. The experiments were conducted under the direction of Mr. Wicksteed, the eminent engineer of the East London Water Works, whose abilities are too well known to the profession to need any praise on our part for the very elaborate manner he has performed his task.]

Upon the 25th of April last, Mr. Francis Whiting called and requested me to give an opinion as to the advantages of using Borradaile's Patent Felt as a non-conductor; and to state what I considered was the actual amount of saving in fuel obtained in the use thereof as a clothing for steam-boilers, cylinders, &c. I stated that, although I never had had the opportunity of trying experiments, I was satisfied it was a good non-conductor, and as the amount of saving stated as having been obtained by those that had used it varied from 6 to 17 per cent., I thought it would be advisable to try a series of experiments upon a large scale, continued for so long a time that the *experience* obtained should put at rest all question as to the actual amount of saving.

Mr. Whiting approved of this suggestion, and gave me instructions to try any experiments I thought proper.

In pursuance of these instructions I determined to ascertain the quantity of water evaporated by a given weight of coals, when the boiler, steam-pipes, and flues were exposed, or not clothed, and also when they were clothed with one, two, three, and four coats of the Patent Felt respectively; having been in the habit also of using hop sacking as a covering for the boilers, I determined to ascertain the evaporative power of the boiler when clothed with three and five coats of hop-sacking respectively, these experiments would give me the proportionate amount of fuel required to evaporate a given weight of water under the different circumstances before stated.

To ascertain the saving obtained by the use of the Patent Felt in clothing the cylinder, nozzle, and steam-pipes, I determined to ascertain the quantity of water that was required to pass through the cylinder in the form of steam, to do the duty of one horse, when the cylinder, steam-pipes, &c., were exposed, or not clothed, and when clothed partially, or wholly, with Patent Felt, as described in Table No. IV. appended to this report.

The boiler on which the experiments were tried was made by Boulton & Watt; it was of that form called wagon-headed, with a flue passing through the centre, the fire being underneath; the dimensions were as follow:

	Ft.	In.
Length of boiler	24	0
Depth	8	8
Width in widest part	5	11
Width of flue passing through the centre	2	6
Depth of ditto ditto	3	0

The engine, which was a single pumping-engine, was made by the same parties, the cylinder 60 inches in diameter, and average stroke 7ft. 11in.; the cylinder had a steam jacket around it.

A long series of experiments was made, the details of which are given in Tables Nos. 1, 2, 3, and 4, appended to this report.

Before commenting upon the experiments, I will give an explanation of the Tables, to show in what way the different results have been arrived at.

Table No. I.

The columns 1 and 2 require no explanation.

Column No. 3, shows the number of hours the engine was at work per diem of 24 hours.

Column No. 4, gives the bushels of coals consumed, which were accurately weighed, each bushel weighing 84 lb., being the weight of the imperial bushel.

Column No. 5, gives the weight of water in hundred weights introduced into the boiler every 24 hours, the way in which this was ascertained was as follows:—There were two cisterns of given dimensions placed one above the other, the top one communicating with the feed pump of the engine, having an overflow, or waste water-pipe attached to it, and a valve in the bottom to let water into the lower cistern when required; the lower cistern communicated with the boiler, supplying it in the ordinary way adopted for low pressure boilers; the lower cistern was gauged, the gauge being divided into hundred weights, the divisions being obtained by actually weighing the water into the cistern; the lower cistern was filled with 21 cwts. of water, and when that was exhausted in feeding the boiler, the feed valve was closed, and the cistern was refilled with 21 cwts. more, so that the actual quantity evaporated was most accurately obtained.

Column No. 6, represents the mean temperature of the water in the lower cistern before evaporation, and was thus obtained: the temperature of the water each time the cistern was filled was taken, and again when it was nearly empty, the mean of all these temperatures is represented in column No. 6. The mean temperature in the line of Totals was obtained by multiplying each weight of water, given in column No. 5, by the corresponding temperature in column No. 6, the products being added together, and divided by the total weight of water, which gives the true mean temperature of the whole water evaporated.

Table No. II

Column No. 1, refers to the totals in Table No. 1.

Columns Nos. 2, 3, 4, 5, & 6, require no further explanation than has been already given.

Column No. 7, represents the pounds weight and decimals of a pound of water evaporated by the consumption of one pound of fuel; the water before evaporation being at the corresponding temperatures given in column No. 6.

Column No. 8, represents the cubic feet and decimals of a cubic foot of water evaporated by the consumption of 112 lb. of coal, under similar circumstances to those given in column No. 7.

Column No. 9, represents the cubic feet and decimals of a cubic foot of water, that would have been evaporated, if the temperature of the water admitted into the boiler had been equal to 212° of Fah., and is obtained thus:* The latent heat of steam was stated by Mr. Watt to be equal to 950°, the sensible heat at the boiling point is 212°, the sensible and latent heat together being equal to 1162°, but as the water to be evaporated (see experiment No. 1,) had already 80·9° of heat in it, the number of degrees of heat required to be communicated to the water to convert it into steam would be 1081·1° only, and if the temperature of the water had been 212°, it would have required only 950° of heat (equal to the latent heat) to be communicated to it to convert it into steam, hence

	Heat.		Coal.		Heat.		Coal.
As	1081·1°	:	112 lb.	: :	950°	:	98·4 lb.

Thus if the temperature of the water had been 212° Fah. before it had been admitted into the boiler, 98·4 lb. of coals would have evaporated as much water as 112 lb. of coals would have done, the temperature being 80·9, hence

Coal.		Water.		Coal.		Water.
98·4 lb.	:	13.43 cubic feet	: :	112 lb.	:	15·28 cubic feet,

in other words, 112 lb. of coal will evaporate 15·28 cubic feet of water from 212° Fah., and only 13·43 cubic feet from 80·9° Fah.

The object of column No. 9, is to show a fair comparison between all the experiments, reducing them to one standard, which is rendered necessary from the circumstance of the temperatures given in column No. 6, varying in each series of experiments.

Column No. 10, shows the amount of saving in fuel under different states of clothing, or exposure of the boiler, steam-pipes, &c., as described in column No. 11.

Table No. III.

Columns Nos. 1, & 2, require no farther explanation than has already been given.

Column No. 3, represents the weight of water passing through the cylinder, or into the steam jacket in the form of steam, in the time stated in column No. 2.

Column No. 4, represents the number of strokes made by the engine in the time stated in column No. 2, which is necessary to be recorded, that the power of the engine may be ascertained.

Column No. 5, is the pressure under which the engine worked, or the height to which the water was raised, and was obtained by noting down every 15 minutes during the time the experiments lasted, the pressure, indicated by a mercurial syphon-gauge attached to the pump, then taking the mean of the pressures so noted down, and adding to it the height from the level of the water in the engine well to the datum line of the mercurial gauge; the mean pressure in the line of totals was obtained by multiplying the figures in columns No. 4 and 5 together, and dividing by the total number of strokes, which gives the true mean of the observations made every 15 minutes.

Table No. IV.

Column No. 1 refers to the totals in Table No. 3.

* Vide Mr. Parke's paper on the evaporation of water from steam boilers ...

Columns No. 2, 3, 4, 5, and 6, require no farther explanation than has been ...ady given.

Column No. 7, shows the average number of strokes made by the engine ... minute during the time of the experiments.

Column No. 8, shows the effective power of the engine, and is obtained by ...ltiplying the weight of water lifted each stroke (which was equal to $20\frac{44}{100}$) by the pressure shown in column No. 6, and by the strokes per ...nute shown in column No. 7, the product being the number of pounds ...ight raised 1 foot high per minute, which, divided by 33,000lb., will give ... horses' power indicated in column No. 8.

Column No. 9, shows the quantity of water (in decimals of a cube foot) ...quired per hour to pass through the cylinder and steam jacket in the form ... steam to produce one horse's power, and is obtained by reducing column ... 4 to cubic feet, and dividing by the hours given in column No. 3, and ...ain dividing the quotient by the horses' power represented in column ...o. 8.

Column No. 10, shows the proportional quantity of water in the form of ...eam required per horse's power under different states of clothing or ex...sure of the cylinder, &c., as described in column No. 12.

Column No. 11, shows the proportionate saving of water by clothing the ...linder as described in column No. 12.

Upon examination of the results shown in the Tables, a description ...f which has just been given, it will be seen in Table No. 2, that when ...he boiler was clothed with *one* coat of Borradaile's Patent Felt, that ...he evaporation was a little greater than when clothed with five coats ...f hop sacking. When clothed with *two* coats of felt it was not su...perior to *one* coat of felt, but when clothed with *three* coats, the evapo...ration was $1\frac{1}{10}$ per cent. greater; and when one coat of felt had been ...aid on the top of the flues, on the flag stones round the boiler, the ...evaporation was increased $3\frac{6}{10}$ per cent., and when the boiler was ...clothed with four coats, and the top of the flues with two coats, the ...evaporation was increased $\frac{7}{10}$ per cent. only: from this it would ap...pear that to produce a considerable saving in fuel, it is necessary to have at least three coats of felt, and that the top flues should be coated with at least one coat of felt.

Upon examination of Table No. 4, it will be seen, that to obtain the greatest effect of saving from casing with Patent Felt, that not only the steam-jacket and steam-pipes should be clothed, but also the cylinder-cover, and steam-nozzle. The result of these experiments, which an examination of the tables will prove to have been carried on upon a large scale, each trial being continued for several days, shows that by properly clothing the boilers, steam-pipes, and flues, with Borradaile's Patent Felt, a saving of fuel of $10\frac{6}{10}$ per cent. may be effected; and by properly clothing the cylinder-steam-jacket, steam-pipes, nozzle and cylinder-cover, a saving of 15 per cent. is effected in the quantity of water converted into steam to produce a given effect: and consequently, the combined result is equal to a saving of fuel of $25\frac{6}{10}$ per cent.

Although the saving in fuel effected may be considered as the greatest advantage in using the Felt, yet there are others of no slight importance which should be noticed.

1st. The saving in the repairs of the boilers; supposing two boilers equally well made, of equally good materials, under which the same quality of coals is burnt, and in which the same quality of water is used, it is very certain that the wear and tear of the two boilers will be in proportion to the quantity of fuel burnt under them; now if the same effect can be produced by using 25 per cent. less fuel under one than under the other, the wear and tear will be 25 per cent. less in one than in the other; now although the actual amount of saving cannot be estimated, as it must depend upon the quality of materials and workmanship employed, which varies in almost every boiler, nevertheless, that it is a matter of importance will strike every one who has had to do with repairs of boilers.

2ndly. In steam-vessels it must be remembered that a reduction in the weight of coals is equivalent to an increase of tonnage, or in other words, supposing a foreign vessel whose cylinders, steam-pipes, and boilers are unclothed, carries in the course of twelve months 4000 tons of coals as fuel for the engines, a reduction in the fuel of 25 per cent. will enable them to carry 1000 tons extra weight of cargo.

3rd. Reduction in the cost of labour in working the engines, especially on board steam-boats. Upon this point it is not necessary to say more than that, by reducing the quantity of fuel to be used, and reducing the temperature of the engine room, and stoke hole, the labour of the engine men and stokers will be considerably less, and it is very evident a considerable saving may be made in this item of expenditure.

4th. If judiciously applied, the felt will prove a great safe-guard against fire, as it will be seen, by reference to Mr. Aikin's experiments, an account of which is appended to this report, that it may be exposed ... without being affected.

EXPENCE OF CLOTHING.

This, of course, must vary according to the size of the engine and boilers, whether land or marine, engines, &c. &c.; the cost, however, of clothing the engine upon which the trial was made, and *two* boilers with four coats of felt, the engine work covered with green baize oil-cloth, and the boiler with canvas, as herein-before described, was £96; the engine working 12 hours per day exposed, or not clothed, would consume 1100 tons of small Newcastle coals per annum, which, at 17*s*. per ton would be equal to £935; 25 per cent. saving on this would be £233 15*s*. or 251 per cent. profit upon the outlay of £96.

DURABILITY OF THE FELT.

It has been the general practice to coat the boilers, pipes, and cylinders with a mixture of white lead, alum, Paris white, and linseed oil, before the first coat of felt is laid upon it, with the intention of preventing the felt from being scorched from direct contact with the heated metal; and it has been said that the fire which occurred in the Great Western steam ship when in the Thames, on her first voyage, was occasioned by the oil in this composition catching fire; to ascertain how far the use of this paint was necessary, and also what heat the felt would bear without being injuriously affected, I requested Mr. Arthur Aikin to try some experiments, and favour me with his opinion on this matter, and beg to refer you to his letter, which is appended to this report, and which to me appears most satisfactory; I also beg to draw your attention to his valuable suggestion of a new mixture to be applied in the place of that used at present in places where it may be found necessary, as being much more efficacious. With a view of showing the saving which may be effected by the use of the patent felt, I have calculated the Table No. V., shewing the saving in annual expence in proportion to the consumption of coals per annum, and the price per ton.

In conclusion, I beg leave to say that I had not, before I tried these experiments, an idea that the saving would be so great as it proves to be; the experiments have been, however, conducted with so much care, each series has been continued for so long a time, and the coals used having been from the same cargo, that I have not the slightest doubt any person clothing their boilers and engines in the *same manner, and to the same extent hereinbefore described*, will at once effect 25 per cent. saving in fuel, or in case of a boiler and steam pipes alone where an engine is not used, a saving of 10 per cent.

THOMAS WICKSTEED,
Civil Engineer.

Old Ford, August 14th, 1840.

REPORT OF ARTHUR AIKIN, ESQ., F.L.S., F.G.S., &c.

MY DEAR SIR—You inform me that it is customary to cover the outside of steam boilers with a paint composed of lead, oil and alum previous to applying the coating of felt. This you say is done with the intention of preventing the felt from being scorched by direct contact with the heated metal of the boiler. You require my opinion if it is necessary to interpose any substance in order to avoid injury to the felt, and likewise inform me that in one instance a fire was said to have originated from the oil paint becoming overheated.

With the view of answering your inquiries in a satisfactory manner, my first object was to ascertain the utmost degree of heat which felt is capable of bearing without injury. For this purpose I put several pounds of mercury in an iron basin, and then placed another smaller basin on the mercury—in the smaller basin I put a layer of felt, and applied pressure to the upper surface of the felt sufficient to force the bottom of the iron basin in which it was contained, so deep in the mercury that there was only about half an inch of mercury between the two basins. A pot of burning charcoal was then placed below the larger basin, and a mercurial thermometer graduated to 600 Fah. was dipped from time to time in the mercury to ascertain the temperature. When the heat had risen to 300 Fah. a small piece of felt was immersed in the mercury between the two basins, and was withdrawn occasionally as the heat increased, in order to observe the effect produced on it. Up to the temperature of 440° or 450°, the felt appeared to suffer no injury, the colour remaining unaltered; but from 450° to 480° the colour first became deeper, the elasticity of the fibre was destroyed, it then became nearly black, and at the same time gave out the odour of burning hair. The hot charcoal was then removed, and on examining the felt which was in the small basin, it gave out, while warm, a burnt odour, and the surface in contact with the iron had become of a dark brown colour, as you may see in the specimen which accompanies this report. I consider therefore the heat of 440 Fah. as the highest to which felt can be exposed without injury, even for a short time (for my experiment did not continue above an hour), and if the heat were continued for several days, it probably ought not to exceed 400 Fah. If therefore the external heat of a steam boiler is liable to rise to 400 Fah., it would be prudent to interpose some substance between the surface of the boiler and the felt, but for this purpose oil paint with a basis of litharge, red lead or white lead is not to be recommended; for the oxides of lead are, all of them, especially the second, very easy of decomposition when mixed with oil and heated. While decomposing, that is, while the oxygen of the lead is combining with the combustible ingredients of the oil, a considerable increase of heat is excited, and this may, under favourable circumstances, be so great as to produce actual combustion of the oil.

In making experiments with the intention of discovering a composition free from the objections to oil paint, and at the same time cheap, the following occurred to me, and I find on trial that it adheres perfectly well when dry to the surface of iron, and will bear a heat of between 500° and 600° without material injury; it also retards considerably the efflux of heat, and will therefore, I think, be found a very good protection for the felt. It is made as follows:—

Take very stiff clay and sand (that of a bright yellow colour is best), dry them separately at a heat not much exceeding that of boiling water; reduce them to powder and pass them through a moderately fine sieve. Of the sand take four measures, and of the clay two measures, and mix them well; then add one measure of linseed meal, and one measure of horse dung, mixing them with the other ingredients as accurately as possible. Pour into any convenient vessel boiling hot water, and shake into it the above composition by small quantities at a time, observing that the last added quantity is thoroughly soaked before another is put in; there will thus be obtained a slippery semi-gelatinous mass which is best applied to the surface of the boiler by means of a trowel.

The first layer should be very thin, and care must be taken that it does not slip down while wet, when it has become dry it will adhere firmly, and if its surface is left rather rough, the second layer may be applied without any hazard of its slipping.

A. Aikin.

7, Bloomsbury Square, Aug. 6, 1840.

TABLE No. I.

Detail of Coals consumed and water evaporated in the course of 72 experiments, during which there were 4275 bushels of coals consumed, 1287 tons and 8 cwts. of water evaporated.

COMPETITION DESIGNS.

Mr. Sparke in reply to K. P. S.

Sir—In your number of this present month appeared a letter signed K. P. S., containing a charge against the persons who are engaged in building a New Church in this town. I have to request that you will give insertion in your forthcoming number to some observations in reply to those charges.

Your correspondent K. P. S. refers to a letter, dated Oct. 29, 1839, addressed by the Subscribers to the New Church to six Architects, inviting them to send designs for the proposed building, upon certain terms therein specified.

This letter is designated by K. P. S. as "most offensive." But surely it is impossible to conceive that the subscribers* *intended* an offence to the gentlemen with whom they sought communication. The letter indeed contained a clause, obliging the architect, whose design should be selected to carry the work into execution for the specified sum of £3,000, if required by the subscribers so to do. The subscribers, however, learnt that this arrangement was contrary to the practice of the profession, and therefore they at once altered the terms of the proposition to meet the wishes of the architects, who [so far as the subscribers are informed] were perfectly satisfied with the terms as amended, to which they all assented.

Let me now address myself to that point which has led the subscribers to think it proper to take notice of this letter of K. P. S., namely, the charge of bad faith towards the architects.

The substance of this complaint is, that the subscribers selected a

* K. P. S. criticizes the expression "Subscribers," and says "the business was of course conducted by a committee." He is as ill informed on this as on other points connected with this church. The subscribers at large, and not a committee transacted the business K. P. S. speaks of. The building committee was not appointed till after the design was selected.

design, the execution of which will cost £700 or £750 more than the sum mentioned in the instructions given to the architects.

Your correspondent K. P. S. says, "having selected the design, the subscribers proceeded to receive tenders for its execution; and it having been whispered that the estimates of the builders greatly exceeded the stipulated sum, the result was—not that the subscribers rejected the design and chose another—but that the tenders were returned to the builders unopened, and the designs referred back to the architect, for the purpose of being altered, so as to bring it within the means of the subscribers."

This statement is totally at variance with the truth. The first tenders were not returned to the builders, and the design was not referred back to the architect for the reason stated. This course was taken solely on account of an objection to the mode of constructing the roof, made by the Incorporated Society for building Churches; and the objection of the Society was communicated to the subscribers after the first tenders were received.

Your correspondent proceeds, "how the subscribers have fulfilled the conditions they dictated, may be seen by the following statement: The accepted tender amounted to £3550 in round numbers."

This Sir, is not in accordance with the fact: the sum for which the Church is to be completed is £3,353.

K. P. S. continues, "in addition to this, extra foundations, to the amount of £150 to £200, were found to be necessary, not in consequence of any unforeseen difficulty, such as might arise from the nature of the soil, &c."

The fact, Sir, is, that the "extra foundations were required by the nature of the soil." It was necessary to remove a very considerable body of earth for every part of the foundations, and in the site of the tower, the ground was excavated to the depth of 13 feet; and the foundations was made of the best concrete, comprised of lime and gravel, brought from a distance of nearly 3 miles.

"The cost of the building," continues K. P. S., "is therefore to be from £3,700 to £3,750."

This inference is very far from the truth. The sum for which the Church is be completed is, as I have before observed, £3,353. But from this gross sum is to be deducted the amounts of the drawback on the duties upon the customable and exciseable materials used in the building, as was expressly stated in the directions to the architects in the letter dated Nov. 30, 1839. This drawback is estimated at £350.

The cost of the Church, therefore, will amount as nearly as possible to £3,000, the sum which the subscribers have always stated that they intended to expend.

K. P. S. continues, "neither plastering nor painting are included in the contract."

This is opposed to the fact. The walls indeed are not to be plastered, but all the plastering which the subscribers think fit to do, *is included in the contract*; and so also is the painting.

K. P. S. continues, "*instead of 650 sittings in pews on the ground floor, there are but 360; 180 more in open seats, and the remainder on benches.*"

The subscribers have thought fit to substitute for pews of three different widths, seats of uniform width throughout the body of the Church, some close pews, some open pews, and along the middle aisle, benches.

K. P. S. continues, "*instead of stone quoins, there is not an atom of stone in the building but what may be indispensable.*"

This statement also is opposed to truth. There is much more stone in the building than would have been indispensable in making stone quoins: all the weatherings are of stone, as are also the string courses.

K. P. S. continues, "the window jambs, &c., are of moulded brick, not gauged brick, but bricks from the kiln, with good ⅜ joints between them. The side roofs are to be covered with zinc."

I have only to observe that there was nothing in the instructions to the architects which rendered it improper to build in the way that has been adopted.

K. P. S. continues, "the side walls are 2½ bricks thick, but, to save materials, are built hollow, the construction of the rest of the building being in strict keeping."

The inference which an incautious reader might be induced to adopt from this statement, would perhaps be this—that the walls are hollow throughout. Nothing could be further from the fact. There are no chambers, but in those parts of the walls where there is little weight to be supported. In the latter part of the last clause, K. P. S. has been more guarded and prudent than in the rest of his letter, because it is only an insinuation and therefore does not admit of any direct contradiction.

K. P. S. continues, "whether all this is quite acting up either to the letter or the spirit of the instructions of the Incorporated Society, may admit of a doubt at least."

The doubt, Sir, is soon resolved; for the subscribers have the approbation of the Incorporated Society testified by the signature of their secretary upon the plans; and indeed the quantity of materials used in the walls is greater than is required by those approved plans.

"It will admit of a doubt," continues K. P. S., "whether a building with bare walls of ordinary brick, and fittings of naked deal inside, can be exactly said to maintain an ecclesiastical character."

How far the New Church can be said to maintain an ecclesiastical character, must be a matter of taste of opinion; but it is believed that no one has seen the designs of Mr. Ranger, the architect, without admiration of their beauty and their perfect adaptation to the purposes for which the building is required; and that no one has seen the building itself, so far as it has already been executed, without approbation of the mode in which the work is done.

So great a discordance between the statements of K. P. S. and the facts of the case, the subscribers conceive can only have arisen from this cause—that K. P. S. has seen neither the contract nor the building, and therefore neither knows what has been done, nor what it is intended to do. He might have seen both by applying either to me, or to the clerk of the works, and he is quite welcome to do so whenever he pleases.

I am, Sir, your obedient servant,

J. SPARKE, *Hon. Sec.*

Bury St. Edmund's, Oct. 19, 1840.

RANGELEY'S SAFETY ROTATION RAILWAY.

(With an Engraving, Plate XVII.*)*

In the September number of our Journal we gave a short description of this invention, and also in the present number will be found an abstract of a paper read at the British Association, but as we thought many of our readers might feel interested in the proposed novel mode of transit, we have prepared the accompanying plate illustrative of the subject, and which, with the following description, will fully enable our readers to judge of its practicability.

This system consists in the adoption of two parallel lines of fixed wheels along the proposed road, at any moderate gauge, and at a short distance longitudinally from centre to centre of each wheel. These are termed the bearing wheels, which, together with a double pulley, are cast or keyed on to a common axle marked *d* and *e* in the engraving. The axles of these bearing wheels and pullies work in plummer blocks *c*, fixed on to cast-iron beds or bearing frames *b*, which are proposed to be in 12 feet lengths, and secured to three wood sleepers and to each other in the way shown in fig. 3; but to prevent elevating these iron beds much above the surface of the ground, a chamber of masonry or iron is necessary to enable the bearing wheels to revolve free from obstruction. Over every pulley is passed an endless band working into the adjoining pulley each way, so that for any distance that the road may be carried there would be an equal distance of band, but in a series of lengths, equal to the distance from each other, of pulley from pulley. Having proceeded so far in our description, we will now explain the method of action:—A steam engine, water wheel, or other motive power being connected with the pullies at each end of such a series of wheels, and motion given thereto, it would in a short time communicate it throughout; and each wheel revolving in the same direction, it is evident that any body placed on the upper periphery of the wheels, so that it could not quit the track, would be in a short time carried from one end to the other, and in greater or less time according to the greater or less rapidity with which the wheels revolve.

By referring to figs. 1 and 2, it will be perceived that the carriage is without wheels, and in fact a kind of sledge; an iron rail is fixed in the underside of the bearing frame to prevent the rapid wear which would otherwise take place from the friction of the wheels in progressing the carriage.

The safety of this mode of transit arises from a considerable portion of the carriage depending between the wheels, and which is termed the baggage box *k*, and the steady motion of the carriage will in a great measure depend on the load which may be stowed therein. To prevent lateral friction against the wheels on beds, guide wheels are fixed at each end of the baggage box, which will prevent the carriage at any time from quitting the track, and also assist in its passage round curves; a break at each end (for regulating the speed, or stopping the carriage, by slightly raising it, and of course diminishing the friction or bite of the wheels on the carriage), is shown in figs. 1 and 2.

CANDIDUS'S NOTE-BOOK.

FASCICULUS XX.

"I must have liberty
Withal, as large a charter as the winds,
To blow on whom I please."

I. It is somewhat odd that those who profess so greatly to admire St. Paul's, Covent Garden, should not have cared to aim at the same kind of effect, as regards one peculiarity in it. It is almost doubtful, however, whether the circumstance alluded to has been taken into account at all, since it has never been especially pointed out, as deserving to be noted and studied. What I mean is, the projection of the pediment as seen in profile, and the bold shadows—or rather depth of shadow in the tympanum of the pediment. Perhaps I shall be told that this is a circumstance attending the peculiar kind of entablature and cornice there employed, and that consequently the same effect cannot be obtained in the pediment of a portico whose columns are of the Grecian Doric, or Ionic order. Most undoubtedly not, if we are determined merely to copy Grecian authorities, yet not only so slavishly, but so blindly, as not to study such modifications of the originals as shall in some degree give us a tolerable equivalent for what is unscrupulously abandoned in the professed copy, however essential it may be to resemblance. There is no occasion whatever for impoverishing Grecian architecture, yet we do so continually without the slightest compunction, making naked entablatures and pediments, with scanty cornices, absolutely *starving* our buildings, yet congratulating ourselves all the while on the classicality and purity of our taste, and fancying that we are perfectly Grecian, whereas we are no better than architectural paupers, dressed up in old finery of which the trimmings and embroidery have been cut away.

II. Should future generations form their ideas of Grecian architecture from our modern English imitations, prodigious will be their wonder at the praises bestowed upon it; for they will be greatly puzzled to discover in them any of its spirit, or any adherence to its principles—aught of refined taste and artistical feeling. In his recent work on *Kunst-Sinnbilder*, Menzel makes some remarks on the ancient orders and the modern versions of them, that architects would do well to take into consideration. He condemns the recipes and prescriptions for making Doric, Ionic, &c., given by Vignola, Palladio, Serlio, Scamozzi and others, as leading only to the most servile and blind imitation of the patterns so set, and which are certainly not the very best in themselves. Of even the very best examples, too, the continual repetition not only becomes wearisome in itself, but also tends to check all invention in design,—at least as regards detail, and so far degrades the architect from an artist to a mere parrot or automaton. Yet in this as in other matters over-strictness is apt to lead to the opposite extreme of licentiousness: and those who would be shocked at the idea of any innovation in Greek detail, even though it were perfectly in accordance with Greek feeling, feel no scruple whatever in reverting for the sake of variety, to such deformities as the Italian Ionic,—which would be reckoned positively detestable after Greek, were it not, that there is precedent for it, and it is not an invention of our own. Out upon the *servum pecus* of pedants, whose dislike to originality arises from their own incapacity to originate any thing whatever, and who therefore bolster up their own imbecillity by a most convenient veneration for precedent.—In the grounds of Mr. Anderson's villa in the Regent's Park, there has lately been executed a small building, the capitals of whose columns would scandalize such *pseudo-legitimates*, for the very reason that they must charm every one whose taste is any thing better than mere prejudice. Ionic in character, though unlike any existing example, they display genuine artistical feeling, and a perfect knowledge of architectural principles with a thorough contempt for ready-made architectural patterns, and for those who make use of them. By all means, let the Institute procure a cast of that capital; and were the two Professors of Architecture to do so likewise, they might get from it something they now seem to be terribly in lack of.

III. In an article on Modern Churches, British Critic, No. LII, there are many remarks worth attending to, and among others what is there said in regard to the excessive quantity of light admitted into churches generally, in consequence of painted glass having been destroyed or removed from the windows of the older buildings, and its not being introduced into those of modern ones, notwithstanding that the apertures are made as large, and the spaces between them as narrow, as if it were intended to damp the light, and hinder the effect of rawness generally, by glazing the windows with rich material. "Nearly all our ancient churches," says the writer, "from the cathedral to the smallest oratory are now considerably *overlighted*. They are not now seen in their proper dress; but are like the face of nature in winter without leaves or flowers. Thus the interior of Salisbury Cathedral is as light as the open air; nay, in a sense, it is lighter; for out of doors, there is an infinite variety of light and shade, and still greater variety of hue; but in that building, as reformers and puritans have left it, there is no relief, no repose: with inconsiderable exception, all is one equally monotonous, shadowless, colourless medium: nothing recedes, nothing stands out. The proportions suffer; for neither height nor length are felt in the glaring mass of day-light.—The cathedral is reduced to one great airy room. The aisles are no longer depths of shade; the lofty pillars and arches no longer stand out in bold relief, bathed in copious streams of light and colour from the high clerestory windows, every stone from the vaults above to the pavement under our feet seeming instinct with life."—"Our churches having been nearly all built or altered with a view to painted glass, as soon as this essential part of their plan was destroyed, there was immediately found to be double or treble the quantity of aperture sufficient for light. In spite of bad glass, windows wholly or partially blocked up, curtains, galleries, and staircases, lofty screens, and all the other numberless accretions of the last three centuries, they are still greatly too light. The restorations of the present age, by opening windows, substituting larger panes of clear white glass, clearing away heavy screens and partitions, and lowering pew-walls, have in fact accidentally increased the evil, and rendered the glare of our churches, especially those of the later styles, quite intolerable, not only to the mental feeling, but to the bodily eye."

IV. In speaking of Vestries, the writer just quoted is of opinion there is little occasion for them in country churches. Such a place "is useful of course to the *crack* preachers of the metropolis, some of whom sit there and *comfort* themselves during the service, that they may come forth fresh as giants to the event of the day—the sermon." It is said also that Dr. Parr used to illustrate his attachment to rural psalmody, by "*smoking in the vestry* during the performance of the choir"! Considering the character of the publication in which the article appears, these remarks are somewhat freely satirical, though certainly not without foundation; for I myself have been in an exceedingly snug vestry, where there was a delightful blazing fire, and every thing vastly *comfortable* indeed, so much so that I should have mistaken it for the parson's own parlour, had not the sash windows been much higher up from the floor than they are in modern houses; which certainly did not diminish the appearance of comfort, inasmuch as it afforded comfortable assurance that there was no danger of any one's accidentally peeping in.

V. Whether I be censured or not for my last comment, the passage which I shall now quote from the same writer, is so excellent, that I shall be thanked for here introducing it.—"Mere novelty is not *originality*. Many things have never been done; some things have never been thought of, simply because they are unnatural and out of the way. *True originality* is a power of invention or discovery; but whether employed in the regions of science or of poetry," (or of art) "it only discovers or invents what is, in some sense, natural and true. It does not so much *make* new ideas, as *find* what have escaped the minds of others. It conceives ideas which strike us at once as having a sort of self-evident propriety and beauty. Its creations are at the same time like and unlike what we know already,—like, in that they accord with our existent taste and notions;—unlike, in that they seem each to have an individual essence."—This last expression, indeed, is not altogether a happy one: perhaps it would be better to say—unlike, in that some new modification is presented to us, for which there is no actual precedent, but which recommends itself so strongly, and withal appears so obvious that we wonder no one should have hit upon it before.

VI. Shall I venture to quote another observation from the same source? Yes; for what the writer says in regard to the notion of Grecian architecture requiring greater attention to study and rules than Gothic does, is well worthy of attention. "There cannot be a greater mistake. Gothic architecture *appears* less formal and less regular than its ancient rival, only because it embraces *more* elements of calculation,—because it has *more forms and rules of art*." True, most true! A person may go through the whole of Grecian architecture—may learn all the Five Orders, *secundum artem*, in less time than he can make himself acquainted with the varieties of Gothic doors or windows, or any other single feature belonging to that style. Carpenter's Gothic indeed,—or even the Jemmy-Wyatt Gothic is a different matter;—that is *regular* enough, all done *by rule* without any study, and therefore regularly bad, or at least insipid.

ON LONG AND SHORT STROKE STEAM ENGINES.

By John Seaward, C.E.

A popular notion has for a considerable time past prevailed, that a long stroke engine is much superior to a short stroke engine; and it will consequently be found that the practice of most, if not all engineers, is greatly regulated by this idea. On very careful consideration, however, it does not appear that this alleged superiority can be satisfactorily proved. That a long stroke engine, under certain circumstances, may be much more advantageously employed than a short one, is undoubtedly true, but considering the steam engine *per se*, that is without reference to adventitious or extraneous circumstances, it would be difficult to show that the former has any advantage whatever over the latter.

For let a careful comparison be made of a long stroke engine with a short stroke engine; let there be two beam engines of thirty horses power each, both equally well made, but the one having a stroke of eight feet, while the stroke of the other is only four feet, the cylinder of the latter being double the area of that of the former; it being understood that both engines shall make the *same* number of revolutions per minute; the steam passages and valves to be of the same area and capacity; and the two engines in all other respects to be well proportioned and made without any limitation as to space or weight.

Now as regards the mere mechanical effect of the moving power (*i. e.* of the steam) it is perfectly clear that it must be precisely the same in both engines, because the same volume of steam must produce the same mechanical effect whether it is let into a long narrow cylinder or into a short wide one; therefore, if there be found any difference in the efficient duty or economical working of these two engines, that difference must arise from circumstances quite unconnected with the mechanical effect of the steam power.

The only circumstances which really can make any essential difference in the efficient duty or economical working of these two engines are these:—First, the greater or smaller quantity of friction in the various parts of the machines. Second, the greater or lesser radiation of heat from the cylinders and passages; third, the greater or smaller loss of steam by the clearance of the piston at the top and bottom of the cylinder. Fourth, the *inertia* and the impulse of the parts of the machine in motion on the surrounding air.

First, then of the *friction*. It will be found in the working of a well made engine of the proportions of the short stroke engine under comparison, that more than four-fifths of the whole friction are due to the packings of the piston and air pump bucket, and of the piston rod and bucket rod,* and less than one-fifth to the main gudgeons, the end gudgeons, the crank pin and other moving joints about the engine. But the friction of the piston packing will vary as the circumference of the piston, multiplied into the distance which the piston travels. Now in the long stroke engine the piston supposing it to be 30 inches diameter, will move eight feet, and the friction of the packing be therefore as 24, while in the short stroke engine the piston will be about 42·4 inches diameter, will move only four feet, while the friction of the packing will be only as 17. In the same way it can be shown that the friction caused by the packing of the air pump bucket, of the piston rod, and of the bucket rod, is also respectively in the ratio of 24 to 17, in the two engines. With respect again to the friction due to the main and end gudgeons, &c., it is clear that it will be less in the long stroke engine, because in the latter engine, the force acting upon these parts will be one-half what it is in the short stroke engine. Assuming therefore 100 to be the whole quantity of friction in an ordinary engine then, 80 of these parts in the short stroke engine, will be due to the piston, air pump, bucket, &c., while in the long stroke engines the friction of these parts will be as 113 that is $= \frac{24}{17} \times 80$, but the friction on the main and end gudgeons in the former engines will be as 20, and in the latter only 10, making the total friction in the short stroke engine 100, and in the long stroke engines 123, or one-fourth more.

Second.—The *radiation of heat* will be in proportion to the extent of surface, but the surface of the long stroke cylinder, is much greater than that of the short cylinder, whence it follows that the loss by radiation in the former, must be greater than in the latter.

Third.—The *clearance of the piston* at the top and bottom of the cylinder, which will evidently be greater in the short stroke engine than in the long stroke engine. Because the area of piston in the former is double that of the latter, some persons would be disposed to say, that the loss by clearance in the former must be double what it is in the latter; but this is not quite certain, for it is not required to give so much clearance in a 4 feet stroke cylinder as it would be advisable to give in an 8 feet stroke cylinder, the reason of which is obviously that the spring and elasticity of the parts in the long stroke engine, must be much greater than in the short stroke engine, and that they must therefore require more clearance. However, it is probable that there would be more loss in the latter engine than in the former.

The loss of steam by filling the passages and nozzles, as also by the radiation of heat from those parts, must evidently be the same in both engines.

Fourth.—*The inertia and impulse of the moving parts on the surrounding air.* The loss in a steam engine occasioned by these two causes may not be very considerable; indeed as regards what is called the *inertia* of matter in the moving parts, it is doubtful whether any such source of loss really exists; however if it does exist, it is clear that the amount of loss must vary in proportion to the *momenta* of those parts of the machine which are in motion, but as the *momenta* must be as the mass of matter in motion multiplied by the velocity, and as these are evidently much greater in the long stroke than in the short stroke engines, (because the parts in the former, are if any thing, of greater weight than in the latter, and also move at a double velocity,) it follows that whatever loss may arise from the *inertia*, must be much greater (double?) in the long stroke engine than in the short stroke engine. With regard to the loss occasioned by the impulse of the moving parts on the air: it must be admitted that in very slow motions it cannot be very important; nevertheless with a material increase of velocity this source of loss becomes serious; it varies as the extent of surface of the moving parts multiplied into the *square* of the velocity. It is tolerably manifest however that the surface of the moving parts in the long stroke engine, will be, if any thing, greater than in the short stroke engine, and that the velocity of the former will be twice that of the latter; therefore the loss by impulse on the air in the long stroke engine, must be four times that in the short stroke engine.

Beside the foregoing causes, it is doubtful whether there are any others that can produce any material difference in the efficient duty or economical working of a steam engine; at least none that can in any way influence the question now under consideration. In estimating therefore, the advantages of the short and long stroke engines, we have in favour of the former a diminution of loss occasioned by friction, by radiation, by *inertia*, and by impulse on the air; while on the other hand, we have in favour of the long stroke engines, a diminution of loss in the clearance of the piston at the top and bottom of the cylinder. It may be difficult to strike an exact balance between these several sources of loss; but there can be no doubt that in a steam engine the loss by friction is much greater than the loss by all the other causes before mentioned put together; and it is past dispute that the balance of loss as regards these causes, is decidedly against the long stroke engine. (The advantages offered by the short stroke engine as regards diminution of space and weight, although of vast importance, are not here adverted to, because they form no part of the immediate inquiry.)

It may be objected that to select an engine with an 8 feet stroke and a cylinder of only 2½ feet diameter for comparison, is not a fair proceeding, because an engine of such proportions is unusual; and it may be also asked whether, if the principle is further extended by making the stroke only 2 feet, and again doubling the area of the piston, whether the advantage would still be in favour of the short stroke engine?

To this it may be answered that although an engine of 8 feet stroke and 2½ feet diameter of cylinder, may be unusual in this country, it is not so in America; in that part of the world, many engines are employed of very nearly the above proportions, for purposes of steam navigation; and in which engines it is not unusual for the piston to travel at the rate of 300 or 400 feet per minute. Again, as regards the carrying out of the principle by still farther reducing the length of stroke, say to two feet, and increasing the diameter of cylinder proportionately, say to 5 feet; there is no doubt whatever that such an engine would have precisely the same mechanical effect as either of the other two; but the balance of advantages would be against an engine of such proportions; because it would be verging to an extreme on one side as much as the 8 feet stroke engine may be thought extreme on the other side. It may, however, be safely affirmed that the principle applies most powerfully to the case where the diameter of cylinder is the same as the length of stroke; because in that case the proportions are most favourable for the diminution of friction and of radiation, and offer the minimum of disadvantage under the several heads of loss above enumerated.

As it is manifest, therefore, that in all particulars which more immediately affect the beneficial employment or working of a steam engine, the long stroke has no manifest superiority over the short stroke; it may appear strange that so decided a preference should have hitherto been given to the former by the generality of engineers.

* The friction of the slide is not included, as that will obviously be the same in both engines. See remarks on Friction at the end.

Perhaps this is chiefly to be attributed to the circumstance of the long stroke offering on most occasions greater convenience than a short stroke. Much may be due also to fashion. The earliest application of steam power was for the purpose of pumping water in the course of mining operations, and in this sort of work a good long stroke was found to be attended with considerable convenience and advantage. In blast engines, and many other of the earlier applications of steam power, the same result was manifest; the earlier habits and ideas of engineers were therefore naturally associated with long stroke engines. Moreover, the earlier manufacturers of steam engines had neither good machinery nor good workmen; they could neither depend upon the correctness of their proportions, nor upon the exactness of the workmanship: besides, timber and other inefficient materials were formerly employed to a considerable extent in the construction of engines; from all which causes imperfections and irregularities were numerous in the earlier engines, and they were consequently very inefficient. As all these sources of imperfection and inefficiency operated much more extensively against short stroke engines than against long, it is no wonder that the latter soon obtained a preference, and that the prejudice should still continue to exist, notwithstanding the same causes are no longer in operation. At the present day, with our good materials and workmanship, exact proportions and adjustments, a short stroke engine will be found to work as accurately and as perfectly as a long stroke engine.

There is one very important circumstance to be kept in view as regards long and short stroke engines; which is, that whenever an engine of the latter description has hitherto been made, it has always been considered necessary to keep the cylinder nearly of the same diameter, as in the long stroke engine, and to cause the engine to make a greater number of revolutions in proportion to the shortness of the stroke, so that the piston in every case might travel at a nearly uniform speed of about 200 feet per minute. Now, to a short stroke engine, made on this plan, there may undoubtedly be many objections. The more frequent alternation of the stroke—the greater loss of steam by the more frequent filling of the passages and nozzles, and the clearance at the top and bottom of the cylinder—the much greater angular motion of all the bearings and moving joints, thereby materially increasing friction and wear—are all circumstances tending to lessen the efficiency of a short stroke engine made upon this plan. It is clear however that an engine made upon the principle, herein before laid down, is not open to the same objections.

And, as regard the speed of the piston in engines, whatever may be the length of stroke, being regulated to the uniform standard of about 200 feet per minute, there can be no valid reasons given for such rule; no one can prove that double the above speed, or only one-half that speed, might not be employed with equal or greater advantage; it is certain that in many steam engines of the transatlantic world the pistons move at a speed of 300, 400, and even as much as 500 feet per minute, and no substantial reason can be alleged why such engines should not do good duty; indeed it may be safely affirmed, that whether the speed of an engine be 100 feet, 200 feet, or 300 feet per minute, it matters nothing; provided all the parts of the engines are well proportioned for the proposed speed, the efficient duty and economical use of the engine will be much the same: keeping this always in mind, that *the slow speed will be more favourable for the easy and pleasant working of the engine, and for durability.*

This question may however be asked—Since it is shown that the long stroke has no superiority over a short stroke, but on the contrary that the balance of advantage is rather in favour of the latter, is it intended to recommend the invariable adoption of a short stroke engine to the total exclusion of a long stroke? By no means. All that is contended for is, that in every case a length of stroke should be adopted whether long or short that shall prove to be most convenient, and best adapted to the object for which the engines are to be employed; and that an engineer should not be fettered and cramped by any fallacious abstract notions, that what is termed a long stroke engine must necessarily be more efficient than an engine with a short stroke; and that he should not therefore be obliged to sacrifice many other far more important considerations, for the sake of obtaining in every case the longest possible stroke.

The application of steam power for the purpose of navigation has had such wonderful results, the character of the steam engine has become so greatly changed, and the proportions so altered, that a marine engine of the present day, and a land engine of former times can scarcely be recognised as belonging to the same class of machines. The length of stroke of marine engines is probably not more than half what used formerly to be given to engines of similar power for mining and manufacturing purposes, but still no one can say that this departure from old rules and maxims has been attended with any disadvantage; on the contrary, it can be shown to have been most beneficial and glorious in its results; and if a still further departure from old established notions can be proved advantageous for steam navigation, we can have no reason whatever to regret the change.

There is no question that the ordinary beam engine as employed in steam vessels has proved most efficient, and that in its application it has been productive of vast benefit. If however, by a modification of the existing steam engines, these benefits can be still further augmented, and that in an eminent degree, no consideration ought to stand in the way of the proposed improvements. The great and paramount objects to be aimed at in the construction of steam engines for navigation are the following, viz., the greatest saving of fuel, the greatest saving of space, the greatest saving of weight, and the greatest durability of the machinery. The more eminently the marine engine shall combine the above important qualities, the more nearly will it have arrived at perfection; and much as may be advanced in favour of the beam engines generally used for marine purposes, it cannot be considered presumptuous to declare that the system of engines employed in the "Cyclops" and "Gorgon" Frigates is far superior in all the qualities before enumerated.

It only remains to be stated, that the real question is, not whether the stroke of an engine shall be 8 feet or 4 feet; but relates to a difference of stroke, of probably from 7 feet to 6 feet: that is, whether the reducing of the stroke of a 200 horse engine *one foot*, with a proportionate increase of diameter in the cylinder, can be attended with such injury and inefficiency as shall wholly neutralise or outweigh all the important advantages of the Gorgon Engines.

In conclusion, it should be observed that as regards the ordinary beam engines, there are many circumstances of convenience which render it advisable to make the stroke as long as practicable, *i. e.*, the adopting a tall narrow cylinder instead of a short and wide cylinder; for in the arrangement of the ordinary beam engine for marine purposes, it is evident that a considerable space lengthways is required for conveniently placing the slide jackets and passages, the condenser, the hot-well, and the air pump; this necessarily causes a great elongation of the side levers or beams; there is therefore much local convenience in making the stroke long, and thereby having a tall narrow cylinder instead of a short wide cylinder, less strain is thrown upon the beams; the beams become more close and compact, and afford more space for a passage between and on the off-sides of the pair of engines: the cross-heads and fork-heads become shorter, and have much less strain thrown upon them; these are all very important considerations which clearly indicate the convenience and possible advantage of having as long a stroke as possible in the ordinary beam engine. But in the Gorgon Engine none of these considerations have any influence whatever; here there are neither beams nor cross heads; we can increase the diameter of the cylinder to almost any extent without any local inconvenience whatever.

We shall conclude these observations with the remark, that as it cannot be proved that there is any superiority in a long stroke engine, over a short stroke engine, and as it is also evident that there is no disadvantage whatever in employing a short connecting rod, it is therefore clear that the two objections are decidedly absurd and groundless.

OF THE FRICTION IN STEAM ENGINES.

In the preceding pages we have offered an investigation of the comparative merits of the Gorgon, and of the common beam engine; in the course of our remarks it became necessary to advert to the important subject of friction; it will not therefore be deemed misplaced to add a few general remarks upon the nature of the friction, which occurs in a steam engine of the usual construction.

To attempt anything like a correct estimate of the absolute quantity of friction in an engine, would we conceive be very fallacious, because there are so many circumstances which affect the quantity of friction, which are quite beyond the reach of calculation; as for example, the uncertain degree of tightness to which the several bearings or packing may be screwed down—the state of the rubbing surfaces, as to smoothness, polish or roughness—the perfect or imperfect state of the lubrication, &c., all of which are circumstances which have a vast influence on the quantity of friction in a steam engine. From observations which the writer has made he is induced to believe, that in a well made engine, in good working condition, the total amount of friction does not exceed five or six per cent. on the whole power of the engine; but that with no very great change of circumstances this quantity may be increased readily to as much as 10 or 12 per cent.

It happens however that in the preceding investigation, the consideration of the absolute quantity of friction in the engine, is not required; all that is wanted is an estimation of the relative proportions of friction which are due to the several parts of the engines; now this sort of estimation is not very difficult, at all events we can arrive at an approximation sufficiently near for practical purposes.

For, if we assume that all the moving or rubbing surfaces throughout the engine are equally smooth, that all the packings and bearings are uniformly secured down, that all parts are well lubricated: then the comparative quantity of friction in the several parts will be, as the area of one of the rubbing surfaces, multiplied into the distance which it moves up on the other rubbing surface.

We obtain thus the following rules:—

1. For the relative quantity of friction due to the piston, multiply the circumference of the piston by the depth of the packing, and by the distance which the piston moves up and down in the cylinder.

2. For the friction of the main shaft bearings, multiply the square of the circumference by the length of the bearing.

3. For the friction of those bearings which do not revolve entirely round, but oscillate backwards and forwards, as the beam, gudgeons, &c., multiply the area of the bearing into the angular distance moved backwards and forwards during one revolution of the engine, &c.

4. It should be observed, however, that when one of the two rubbing surfaces is hemp packing, the amount of friction will be at least double what it will be when both surfaces are metal.

5. Furthermore, there are certain bearings which receive the direct strain of the engine, while others do not. The following receive the direct strain, viz.; the crank pin, the fork head gudgeons, the main gudgeons, the upper and lower bearings of the side rods; now the quantity of friction upon these several bearings will be considerably more than that which is simply due to the tightening down of the bearings, as before assumed; it is difficult to say what may be the increase of the friction from this cause, but it will be safe to assume that the friction on these bearings will be three times greater than what is due to the other bearings.

Upon the foregoing principles therefore, is calculated the following table of the comparative friction of the different parts of an engine, having a 40-inch cylinder, a 3½-feet stroke, and furnished with the common D slide.

Table of Comparative Friction of the moving parts of a Steam Engine.

2 (rule 4)	125½ in. circum. 4 in. deep. 84 in. dist.	84·336	Piston, with hemp packing 4 in. deep, moving a distance of 84 in.
2	13 in. circum. 4½ in. deep. 84 in. dist.	9·828	Piston rod, hemp packing 4½ in. deep, moving 84 in.
2	82 in. circum. 3 in. deep 42 in. dist.	20·262	Air pump bucket, hemp packing 3 in. deep, and moving 42 in.
2	8 in. circum. 3½ in. deep 42 in. dist.	2·352	Bucket rod, hemp packed 3½ in. deep, moving 42 in.
2·2	12 in. circum. 3 in. deep 42 in. dist.	6·048	Two plunger poles, with hemp packing 3 in. deep, moving 42 in.
	15 in. wide 8 in. 2 faces deep 14 in. dist.	Flat face 1·680	The slide face metal and metal back hemp packed, 6 in. at top, 6 in. at bottom, moving 7 in. each way.

3 (rule 5)	15¼ in. circum. 6 in. long 15¼ in. dist.	4·323	Crank pin, moving entirely round and receiving the direct strain of the engine.
3-2—	10 in. circum. 3½ in. long 2½ in. dist.	·525	The two fork head joints moving at an angle of 45° each way, but receiving the direct stain of the engine.
3-2—	10 in. circum. 3½ in. long 2½ in. dist.	·525	Two lower bearings of side rods same as fork head joints.
3-2—	18 in. circum. 7 in. long 9 in. dist.	6·804	The two main gudgeons receiving the strain of the engines and moving 90° each way.
	45 in. circum. 13½ in. deep 45 in. dist.	3·543	Eccentric ring moving quite round.
		1·000	Sundry small joints.
		163·123	

Therefore, if it be assumed that the total quantity of friction in a steam engine is as 163·123, then will the relative quantity of friction in the several parts be nearly as is represented by the numbers in the preceding table.

ON THE THEORY OF TOLLS UPON CANALS AND RAILWAYS.

Sir—As I am aware that Mr. Ellett's remarks on Canal and Railway Tolls, extracted in your Journal for September, have attracted some attention, and have been received as sound and judicious principles by some persons, who are in a position which enables them to carry out these principles into practical operation, I beg to offer a few observations, with the view of pointing out what I conceive to be erroneous in Mr. Ellett's statement.

Mr. Ellett's object is, so to regulate the charge of toll upon a canal or railway, as that every part of the country through which the line passes, near or remote, may derive from the improved mode of conveyance the same advantage, an equal share of trade. And he contends that this cannot be effected by the system of tolls that generally prevails, namely, a fixed mileage, or a certain rate per ton per mile; and he therefore recommends the adoption of the directly opposite method, viz., that the lowest charge should be levied on the trade that is brought from the greatest distance, and increasing gradually as we approach nearer to the mart or place of consumption, that the heaviest toll should be charged on that which comes the shortest distance. And Mr. Ellett then proceeds to show that this plan would produce the largest trade, (that is, would command the largest extent of country,) and the greatest amount of revenue.

Now all Mr. Ellett's argument depends upon one little assumption, which he quietly introduces, without remark or explanation, quite unconscious that it contains the grossest fallacy. The market price of any commodity at the place of consumption may be said to be fixed, (for our present purpose,) and, in order to obtain a sale for this commodity brought by the canal or railway, the cost of production and the expense of conveyance must not exceed the fixed market price. Mr. Ellett takes for granted that *the cost of production* is fixed also, and on this rests the whole theory of tolls. "Let us also assume that the cost of producing this article (lumber) is 6 dollars per ton," and the market price being fixed (10 dollars,) he consequently assumes that the extreme cost of carriage which the article can bear, so as to be sold in the market, is fixed too, that it must not exceed 4 dollars, in the instance given. But he assumes also, and it follows in like manner from the preceding assumption, that *the cost of production is fixed*, that the article can always bear this fixed charge of 4 dollars, that whether the commodity be brought from near or far, whether it is carried 100 or 400 miles, it can always bear the full charge of 4 dollars for carriage, and cannot, in any case, afford more. And on this assumption Mr.

Ellett builds his theory,—that as the cost of carriage consists of two parts, the actual expense of conveyance, including the maintenance of the canal or railway, called *the freight*, and the profit of the canal proprietors, called *toll*; and as the freight must necessarily be directly proportional to the distance, the toll (their sum being fixed) should be inversely proportioned thereto.

Even were this principle correct in theory, it would in practice be exceedingly unjust, and therefore injurious. For nothing can be more unreasonable than that the trade which passes along the canal but 50 miles, should pay three times as much toll as that which comes 150 miles, thus paying actually *nine times* its due proportion. Let it be observed also that Mr. Ellett's system is one that can be fully carried out only on such a canal or railway, as has to sustain no competition with common roads. On the latter the charges of conveyance will always be directly proportioned to the distance, and being lowest for the nearest parts, will of course successfully compete with the canal or railway, whose toll is *here* the highest. The maximum charge for conveyance being 4 dollars, and supposing with Mr. Ellett that land carriage is five-fold more expensive than by the "improvement," it will, according to the scale given by him, be cheaper than the canal for the first 40 miles, (one-tenth of its whole length,) and from so much of the country, therefore the canal will derive no trade. With us the proportion of the cost of land and canal carriage is much nearer, perhaps greater than two to one; and the portion of the country commanded by the superior cheapness of land carriage, under Mr. Ellett's system of tolls, will be proportionately larger. Wherever there is the competition of another conveyance, on which the charges are made according to the distance, the inverse system of toll will be impracticable.

Leaving, therefore, for the present, the practical objections to Mr. Ellett's proposed system, I turn again to that which forms the basis of his whole theory, and which I conceive to be a most fallacious assumption. I am indeed surprised that any one writing upon such a subject, who ought to have some acquaintance with the principles of Political Economy, should hazard, or should carelessly make, an assumption so opposed to the mere elements of that science, as well as to ordinary experience. So far from *the cost of production* of any article being a fixed sum, throughout an extensive district of country, it is dependent upon, and varies exceedingly with, a great many circumstances. Every one knows that there is a difference of prices in many markets throughout the kingdom, and the price *at the place of production* is, *generally*, the actual cost of production, added to the usual profits. For reasons which will be noticed hereafter, the cost of production, and consequently, prices differ less in an improved country like England, than in one possessed of fewer artificial advantages, such as America or Ireland. But the fact is notorious to every one, that differences do exist in the expenses of production, at different places, of commodities of the same quality, and of equal value at the place of consumption.

The cost of production is made up chiefly of rent, the wages of labour, and the profits of the producer, (and, in manufactures, of the price of the raw material.) *Rent* is well known to vary exceedingly in different parts of the country, even for lands of the same kind, and equal fertility. *Wages* differ too, not only between the manufacturing and agricultural districts, but also between different districts engaged in the same occupations. Profits differ likewise, but being nearly in a fixed proportion to the total cost, they need not be considered separately. As, then, the component parts of the cost of production thus vary throughout the country, their sum, the total cost, cannot be said to be fixed. Yet Mr. Ellett seems to have forgotten these facts, palpable as they are to every man's observation.

There are, however, certain articles whose value is very small, and the cost of production of which consists merely of the wages of the labour employed upon it; and this labour being of the coarsest kind, its wages vary but little. Of such commodities the expense of production cannot differ much, and may be said to be fixed. Such are stone, lime, and, in a wooded country like America, timber, and perhaps coal, ores, &c. It is to such products Mr. Ellett chiefly applies his theory, but he does not confine it to them. He intimates that some other principles come into operation with reference to the more valuable articles of trade. But as I have not seen his observation on that part of the subject, and as it appears to me that his principle, if correct, must be equally applicable to every branch of trade, and as I know that it has been so interpreted and applied by some of his readers, I have discussed the subject generally, endeavouring to refute the theory in its application to either division of canal trade. In certain cases, then, it would appear that Mr. Ellett's assumption is correct, that the cost of production is fixed (or nearly so). But it so happens, that in these instances, our author's system of tolls would be altogether impracticable. The commodities are of such little value as to be scarce worth removing, unless at a very small cost; they cannot, in general, be brought from a distance, the necessary charge for freight, even if there be no toll, acting as a prohibition; and to have any trade, even from the nearest places, you must levy only the lowest rate of toll. Thus on the Irish Grand Canal the toll on stone is 6*d.* per ton, and on manure 4*d.* per ton for any distance,—because at higher rates they would scarcely be carried at all. And here, it is evident, there is no room for graduation according to Mr. Ellett's plan.

But resuming the consideration of the cost of production, where it is not fixed, let us examine into the causes of the differences that exist; why rent is high in one district, and low in another, and why wages vary so much as they are found to do in different parts of the country. Of course they all depend upon the economical principle of the relation of supply and demand. But in the same country, all parts of which are subject to the same laws and conditions of trade, and all contribute to the supply of the same great market, this relation between the supply and demand, that is the different values of rent and wages in the various parts of this district, depends mostly upon their respective distances from the place of consumption, and the facilities of conveyance thither. Near a large town, rent and wages, and consequently the cost of production, are high, because there the great demand can be most easily supplied, and with very little expense for carriage. Farther off, as the cost of conveying the products to the markets increase with the distance, both rent and wages are lower. And if a canal or railroad be made into the country, as it cheapens the cost of conveyance, and thereby facilitates its supplying the market, it raises rent and wages, or the cost of local production. Thus the true state of the case is very different from Mr. Ellett's theory. The cost of production is not fixed; it is found to depend on the charges for conveyance, varying inversely with them, (not in the same ratio,) that is, with the distance. Of course I speak here of the natural charge for conveyance, which consists of *freight* only, and is always proportionate to the distance. Such is the cost of carriage upon common roads, and as these are generally the first modes of conveyance, and the most universal, it is by the principles and circumstances that relate to them the cost of production is generally governed. In England the facilities for transport are so great, and so equally diffused throughout every part of the country, that the difference in the cost of production in different places is small, as I before mentioned. But in countries where the improved methods of conveyance are few, the difference of price, or the cost of production, at places at unequal distances from the market, or not having the same facilities, is often very striking. In Ireland, the price of potatoes, for instance, is frequently found to differ to an astonishing degree, in various parts more or less remote from the large towns; and the only cause appears to be the expense of carriage, which being in proportion to the distance, increases or diminishes the cost of production and the facility of removal.

If, then, the cost of production is found to vary, and inversely with the distance, the difference between it and the market price is not fixed, but varies directly with the distance; and the total sum which the commodity will bear as the cost of conveyance to the market is a varying quantity, increasing with the distance. The freight, one of its parts, is proportioned to the distance, and the other portion, the toll, should also, in general, be regulated by the same proportion. There are, of course, many circumstances which modify this law, at least in practice; but looking at the abstract question, I think that the theory of tolls, which the principles of economy and the laws that govern the relations of value and price indicate, is the simple, natural, and just system of charging according to the distance, in proportion to the benefit conferred, or to "the value given."

This is not only the true theory, but it is also the only system that is practicable, wherever there is the competition of common roads; it is easy to show that, in all cases, it would be the most profitable system also,—the most productive of revenue to the proprietors of the canal or railway; and at the same time the most impartial, and the most equally advantageous to every part of the country. Each district has its own advantages, in which it is superior to the others, and, under a natural system, its facilities for production and transport are proportioned duly to its means; while the retrograde principle must have the effect of encouraging the remoter districts, and depressing the nearer,—by destroying the natural and equable balance, which prevails in the social commonwealth.

I cannot trespass on your space, Sir, by entering further on the proofs that the natural system is also the most productive; neither could I do so without introducing diagrams, which would be found to differ very much indeed from those of Mr. Ellett. I shall only add, that I hold the true and most effectual mode of gaining for a canal or railroad the largest amount of trade and revenue to be MODERATE TOLLS, charged fairly according to the distance. I am convinced that the charges upon most canals and railways are much too high; that considerably lower rates would greatly increase their prosperity, and add vastly to the resources and commercial facilities of the country. Wherever the experiment of reduction has been tried, I believe it has proved successful, in augmenting the trade and its profits; and I have no doubt that soon the proprietors of many public works will be compelled, for their own sakes, to resort to such measures; and it is, therefore, of much importance that the principles of "the theory of tolls" should be clearly understood; and, conceiving that those advocated by Mr. Ellett are fallacious, unjust, and injurious, I have endeavoured to refute them,—and regret that the task has been so feebly and hastily performed.

C. E. B.

ON COMPETITION DESIGNS.

We receive many letters on the subject of Competition, which are almost unanimous in complaining of the UTTER WANT OF GOOD FAITH on the part of those who invite architects to send in designs. And though we are sorry there should be room for such complaint in any instance whatever, we are glad to find that the evil itself prevails to so shameful an extent, because it is now likely that the profession will be stirred up to adopt some decisive measures to correct it. They certainly ought to do so; and we should advise a public meeting to be convened by them for that purpose. In the meanwhile our own pages shall be open to the exposure of the impositions now practised under the mask of Competition; and no doubt, many a strange tale might be unfolded that would open the eyes of the public to the mysterious doings of those Secret Tribunals which exercise an arbitrary and irresponsible power, and generally no less injuriously to the interests of architecture and good taste, than unjustly towards individuals in the profession.

From among the letters addressed to us on the subject, we give the three following as being well worthy of the attention of our readers, though we dare not promise the writers that their remonstrances will produce any effect.

Sir—The exposure made by your correspondent K. P. S. relative to the Bury St. Edmund's affair, ought to produce some good effect, yet that any is likely to result from it is more than can reasonably be anticipated; for not only are committees—even though composed of "all honourable men," perfectly callous to any thing like shame, but there is a sad want of energy in architects themselves, or they would even now have taken some decided steps to check the scandalous abuses—I may say, the barefaced impositions and deceptions attending competitions.

If there is positively no remedy for the evils complained,—why then in the name of common sense let them be endured, without any pitiful whining on the part of those who choose to lend themselves to a system of humbug.—Well, I have said *humbug*, and although that word is certainly not the most delicate, there is hardly another in the language that would be so appropriate, unless it were one more offensive still.—But remedy I am persuaded there is—at least to a very great extent, provided we choose to adopt such measures as will secure it. No doubt, there are many difficulties to be first overcome; but that, I conceive is a reason the more, why they should be boldly encountered, and the task of reform be set about with fearless resolution. Such reform ought to have been carried through by the Institute; because that Body might have taken up the matter actively without incurring the invidiousness and risk to which individuals might expose themselves by so doing. There was, indeed, an attempt of the kind, and a most feeble one it was,—amounting to nothing more than a little *palavering*. It would therefore have been greatly more to the credit of the Institute, had the subject never been brought forward at all; because now it looks as if the present vile system of competition was formally acquiesced in by those who ought to leave no stone unturned until they correct it. But there have been two other opportunities which, had they been properly turned to account, might have gone far towards bringing about the so-much-desired reform. As you will perhaps anticipate, I allude to the Nelson Monument and Royal Exchange Competitions, in both of which those who engaged in them, suffered themselves to be more injuriously and contemptuously treated, without venturing to protest against it. With regard to the first one, nothing could be a more insulting piece of mockery than the pretended Second Competition—without any warning on the part of the Committee, that they were decidedly in favour of some kind of Column;—although the result too plainly shows that they were predetermined to adopt Railton's design;—for had they not been so predetermined, they would at least have decently expressed their regret that they should have been driven into so particularly awkward a situation, being under the necessity of confirming their first choice, though aware that it would be in opposition to public opinion. No explanation, however, was offered—and what is much more, none was demanded by the Competitors.—Pity would be thrown away upon such pusillanimous creatures; for they have shown that they deserved to be kicked.

Had a bold and resolute stand been made then,—and the public would almost to a man have supported them;—had they called the Nelson Committee to account, and let the latter know that they were not wholly irresponsible: there can be no doubt but that it would have served as a most wholesome warning to the Gresham Committee, and the Royal Exchange competition would have been conducted very differently from what it has been. But in that, too, the Competitors have allowed themselves to be kicked like spaniels; and the authors of the Eight Designs which obtained the approbation of the professional umpires, suffered themselves to be set aside, and not permitted to try their strength again!

Tame, spiritless, pluckless! they have been served rightly, but THE CAUSE!—that has been most cowardly betrayed. Had those competitors been firm, the Committee would have chaunted *Peccavimus* in full chorus. Had not those Competitors been milk-livered the Committee would have blushed like boiled lobsters. But now, *Actum est! Perii!* And with such a memorable example—such a fatal precedent before them, future Committees may laugh at both competitors and the public.—There is but one chance left: and that is to urge Reform in Competition, incessantly; to discuss it in every possible shape, and without intermission;—and, not least of all, to insist in future upon Pre-exhibition of Designs,—not for merely a day or two, but for sufficient length of time, according to the number of drawings.

I remain, &c.

P. S.

Sir—Apropos to the subject of Competition there is an anecdote now circulating of so extraordinary a nature that it ought to be either publicly confirmed, or publicly contradicted. Reporting it, just as I heard it, the case is this: from among the designs sent in for the Protestant Memorial at Oxford, that by Mr. Blore was *unanimously* chosen, consequently whether such selection was actually the very best or not, it is evident that it was judged to be so by those who made it. But they afterwards discovered to their astonishment and mortification that they had clapped the saddle on the wrong horse, for misled by the name, they had decided in favour of that design, taking for granted that it was by *the* Mr. Blore who has been employed at Buckingham Palace, &c. As soon therefore as they detected their error, and ascertained that *their* Mr. Blore was a different individual, and one comparatively unknown in the profession, they came to the worthy resolution of setting aside the design, which had previously been approved of by them merely through *mistake!* Is not this a most delicious anecdote? Does it not speak volumes as to the sort of discrimination, and the kind of integrity and good faith, displayed by *gentlemen* on such occasions? And mark you, I pray, this extraordinary tergiversation was not manifested in a paltry hole-and-corner competition in some obscure town and village, but in—Oxford!—the seat of learning, and of orthodoxy.

Unless the matter is altogether misrepresented—in which case it becomes the duty of those who are concerned in it, to clear themselves from so highly injurious a charge,—Mr. Blore has sufficient grounds for bringing his action for damages against his quondam judges; and would no doubt obtain them to a very heavy amount, because he has not only suffered pecuniarily, but may be said to have been stigmatised in his professional character, having been formally set aside as incompetent, consequently placed in a very different situation from the other unsuccessful competitors.

Delenda est Carthago: the Humbug and Deception now attending Competition must be blown up,—the present system must be entirely reformed; and as the Institute will not exert itself at all in the cause, so much the more manfully must individuals do so. The pen and the press must bring the subject continually before the profession and the public, until both shall be completely roused: and then, perhaps, when the needed reform shall have been commenced by others, the Institute will valiantly proffer their services, and come forward to share in the merit of the victory.

I remain, &c.

J. P. M.

Sir—In the No. for this month of your excellent Journal, there is an article on Architectural Competition signed "K. P. S.," in which some "facts" are detailed relative to that subject, especially as relates to a church to be built or now building at Berry.

If "K. P. S." was aware of how these matters are managed with us in Ireland, it might excite his honest indignation still more, as the system generally adopted here is to place all the competition designs submitted into the hands of a favoured architect, from which to choose and model such plans as the committee may direct, who *kindly* indulge the favourite with the necessary time.

It may be supposed that the writer is a disappointed candidate, and that this is merely the ebullition of his chagrin and mortification from defeat. Not so; for having had the benefit of seeing the fate of others on these occasions, he has invariably steered clear of this species of competition.

An instance of the flagrant injustice done in this way took place a short time since, wherein architects were invited by public advertisement to send in plans for an edifice to be erected near Dublin, to be appropriated as a place of worship. After the plans, &c., had been sent in, considerable shuffling took place on the part of the committee. At length, after frequent postponements and delays, it was announced that none of the designs, in their judgment, were suitable to the required building, although they numbered upwards of a dozen designs, some of which were shown to me previously, and possessed (in my opinion) very great merit, and were in strict accordance with the rules laid down in the advertisement. In a short time afterwards the building was begun, after the design and inspection of an architect who had not competed, and as the building is now nearly completed, I can, without fear of contradiction, assert that it is a "fac simile" (as far as I have been able to examine it) of one of the designs I had been shown, and which was sent in to the committee.

The profession of an architect is completely degraded in Ireland; for instance, in the erection of any county public building (the architect, if indeed any be engaged at all) is merely a subordinate to the county surveyor, who, with very few exceptions, know nothing of our profession, and until the clause which relates to this subject in the present Grand Jury Act is remedied, things must remain in this state. At present every public work is placed in their hands, and, generally speaking, when anything architectural (or at least what should be architectural) is to be done, they attempt it themselves, and a pretty finish they make of it, instances of which are but too numerous.

Again, a paragraph is now going the round of our papers, eulogizing a new Saving's Bank erected in Limerick, "*by Sir Thomas Deane, the* EMINENT ARCHITECT, *the progress of the work was superintended by William H. Owen, Esq.*, CIVIL ENGINEER, *whose professional taste and skill are so highly appreciated.*"

Not wishing to occupy too much space in your valuable journal, I have merely glanced at some of the strange doings perpetrated here, which, if properly "*shown up*," would undoubtedly throw the grievances complained of by K. P. S. into the shade.

I am, Sir,
Your very obedient servant,
J. A., Architect.

Dublin, Oct. 12, 1840.

LAND SURVEYING.

SIR—I should not trespass on your very valuable time, and on the pages of your most deservedly popular Journal, did I not know that you make it your study to give publicity to every thing, however trifling, which may be of use to any member of the profession, whose interests you so very ably advocate on all occasions. Should this obtain your approval, your insertion of it will much oblige the writer.

It has, I dare say, occurred to every one engaged in an extensive survey, that there is a great danger of mistakes taking place in the change of pins in a long chain line; as the number of changes or removes must be kept in memory, and one is very likely to become confused if there are a great many of them. To obviate this inconvenience, I would beg to propose a very simple plan, viz., that the leader should be provided with a small bag, containing a number of common marbles, such as school-boys employ in their games; and that on giving up his pins to the follower, or hind chainman, at every remove, he should give him one of these marbles, to be kept by the follower in another bag provided for the purpose, until they arrive at the end of the line; when each marble will stand for 10, and the pins in the follower's hand, as usual, for single chains.

By this method nothing is left to the memory, and of course a greater degree of certainty is obtained.

I have the honour to remain, Sir,
Your most obedient servant,
E. WILLIAM MANSELL.

Dublin, Oct. 2, 1840.

LAND SURVEYING.

SIR—I observe in your last Number an extract from Mr. Bruff's Treatise on Engineering Field Work, wherein he says, in describing the new instrument for measuring the contents of maps, that "the principle of the plan has been long known to some few surveyors, but that they prudently kept it to themselves, &c." Now, Sir, I should very much like to know the names of any surveyors to whom the instrument was known before its introduction into the Tithe Office, and perhaps Mr. Bruff will be good enough to afford this information through the medium of your Journal, as it is certainly important to know to whom surveyors are indebted for the invention of this instrument, which most justly deserves all the praise that can be bestowed upon it.

I beg it to be understood, that in seeking this information from Mr. Bruff, I am actuated by no hostile or cavilling spirit, on the contrary, I think generally the contents of his work are most valuable, and strictly to be depended on; in this instance, however, I think he is misinformed, and believing that Mr. Bruff would not wish to deprive the inventor of his due share of credit, I trust he will have no hesitation in stating publicly, who are the parties to whom he alludes, as having long known the principle of the plan.

I am, Sir, your obedient servant,
AN OLD SURVEYOR.

London, Oct. 15, 1840.

THE NELSON AFFAIR.

MR. EDITOR—I send you some stanzas which you may, if you like, suppose were intended to have been put into the foundation stone of Railton's Column, but somehow or other escaped that honour; allow them therefore to be preserved in one of your columns.

ANTI-STYLITES.

NELSON *loquitur*:—

You see that I stick to my *post*,
Stuck up here on the top of a peg,
And having before but one arm,
I am now left to stand on one leg.

Though not on a leg made of wood,
Oh no!—'tis a leg built of stone;
And so wondrous tall too it is,
That I stand "all aloft and alone,"

Just after that whimsical fashion
Old Simeon adopted of yore;
But then he was a saint most sublime,
And his practice a bit of a bore.

Yes, my case is confoundedly hard,
Tho' some other folks' heads are quite soft,
So I wish they had left me *alone*,
Before they had left me *aloft*.

For Wightwick I see there is sneering,
While others are laughing outright,
And folks seem myself to be queering,
While they gape at my pitiful plight.

O! were but the stick I am stuck on,
A good walking-stick—by my fay,
I would not stand here to be quizzed at,
But with stick and all *walk away*.

PNEUMATIC OR ATMOSPHERIC RAILWAY.

SIR—The fairness that should guide a public Journalist, and a scientific one especially, will doubtless induce you to afford me a place to reply to an invidious article contained in your Journal for July, which does me great injustice—has an injurious tendency, and at the same time confers approbation on Messrs. Clegg and Samuda, who are endeavouring to avail themselves of the result of information communicated to them, whilst they were confidentially employed by me in 1836-7-8, in the construction of works and machinery designed for carrying into practical operation the pneumatic or atmospheric railway, which was intended to be applied on the Birmingham, Bristol, and Thames Junction Railway at Wormwood Scrubs, as the first prospectus of that railway (1835) will show, and on which line my invention is now pirated by Clegg and Samuda.

The article in your Journal appears intended as a disparagement of my invention. I have before publicly accused those persons of the conduct complained of in the Sun newspaper of the 17th and 19th June last. I am preparing to stop their proceedings through the medium of a court of justice, but that is no ground for my sustaining in the mean time injurious remarks, and the public mind abused through the columns of public journals.

I am prepared to prove that the system carried into effect, even in all its minute details, is wholly my invention; as well as the more improved applications of the same principle, as specified in my patents of 1834 and 1836, all of which are legally held by me under the authority of the Patent Laws, which forbid those persons or others from using any portion of that which is described in the article inserted in your Journal.

In regard to the remarks that "the idea of employing the power of the atmosphere against a vacuum created in an extended pipe laid between rails, and communicating the moving power thus obtained to propel carriages travelling on a road, we believe originated with Mr. Medhurst, in 1827, and that in 1812 he published some ideas on this method." And that "about 1835 some experiments were made with a model in Wigmore-street, by Mr. Pinkus, very similar to those described by Mr. Medhurst; these experiments, however, failed from the same cause probably, which prevented Mr. Medhurst from carrying his into effect, viz., the impossibility of making an air tight communication from the inside of the pipe to the carriage, tight enough to allow a useful degree of rarefaction to be produced."

Now, Sir, I have to complain that not even so much as one particular of all the allegations in the above quotations is true, and declare that I can disprove them all by documentary evidence of record, and printed publications of old dates. Myself an humble labourer in the field of science, I trust I shall never be guilty of that meanness of mind that would detract from another the merit justly due to him for any mental production, and I will contend for equal justice to myself.

First, then, the merit, and it is a high one of "employing the power of the atmosphere against a vacuum," and transmitting that power, as well as the suggestion of obtaining a similar power by plenum (the latter though impracticable) is due to the celebrated Papin, who suggested them 120 years ago, and not Mr. Medhurst.

Second. The suggestions and the experiment "employing the power of the atmosphere against a vacuum, and by impelling a piston through a tunnel," is due to Mr. Valance, who did it at Brighton in 1824, and not to Mr. Medhurst, who in 1810 only proposed the *impractical part of Papin's plan of forcing air under the compression of many atmospheres*, as several others before him had done; and added at a subsequent date the idea of moving a piston through *an underground tunnel*, by forcing in *air behind it*, from distances of 20 miles apart, and so impel goods and passengers therein. In 1824 Mr. Valance took out a patent for his method of an *underground tunnel*, and the *more correct and practical principle* of rarefaction and atmospheric pressure.—Mr. Medhurst, who held no patent, made claim to Mr. Valance's invention of transmitting a piston through an underground tunnel.—Mr. Valance in a pamphlet of that date, answered Mr. Medhurst, and pointed out in what his invention differed from the other's claims; thus both Papin and Valance went before Mr. Medhurst.

In 1826, not 1835 as is alleged, I proposed to apply Papin's principle by a new method, combination of apparatus and machinery, whereby I was enabled to transfer the power generated under *partial vacuum to the exterior of extended* mains or pipes laid on the margin of a canal or railway, and transmitting the power so generated along such main. I combined the main with a canal, and proposed to use Brown's Gas Vacuum Engine as the prime mover, my plans and specifications were recorded, my models constructed and exhibited: these contained such a mechanical arrangement for effecting a propelling power under rarefaction, *as alone admits of its application at all*; subsequently they became the subject of the first patent (1834) ever taken out for that object. As I was for the first time informed in 1836, Mr. Medhurst in 1828 reprinted his pamphlet of 1810, for the Underground Tunnel and the application of a *Plenum*, and with it, now for the first time proposed to transfer the power to the outside of the underground tunnel, and to have stationary engines 20 miles apart for forcing in air, he shewed a lithographic drawing of the method, and having 4 years before claimed the plan of Valance, and 3 years before of my method of transferring the power of partial vacuum to the exterior of a main he proposed a long box and a pipe suspended over a channel of water in order to make a water-joint; these suggestions made at that late date, were nevertheless so crude and undigested, as to be utterly impracticable as they show. His calculation based upon them he can in no way obtain. He never made an experiment, as I am well informed, and his pamphlet was in the hands only of private friends; I saw one, for the first time, in 1836. Having been engaged until 1830, I in that year again prepared fresh plans and specifications, such as are now enrolled, and exhibited them to friends. In 1833 I commenced my patent, sealed in 1834, and in that year constructed a large working model that was publicly exhibited, *and upon its success in 1836* an association for working my system was formed, which is now extant; contracts were made for works to demonstrate the principle with my subsequent improvements, for which patents also were taken out in various countries. The works were designed to be applied on the Birmingham Bristol and Thames Junction Railway, at Wormwood Scrubs; those works were nearly completed, the line half a mile in length formed on the margin of the Kensington Canal, which was united with that line of railway. Samuda and Hague were the contractors for the engines, the former as well in the construction of the pneumatic mains and valve, and Samuel Clegg was confidentially employed and consulted, and witnessed the progress of the experiments during such employment, learned from me all the minute details that they have now carried into effect, but which are nevertheless held by me under patents. Clegg and Samuda saw my experiments in 1835-6 made upon rough models, but which were attended with perfect success, only some of the details were purposely omitted until further patents were sealed.

Not only, therefore, is the invention in all its details my own, and legally held by my patents, which embrace such mechanical combinations, as without which that well known principle cannot possibly be carried into effect, but I shall, when my interest best requires it, stop their further progress.

I am, Sir, your obedient servant,

H. Pinkus.

11, *Panton Square, Aug.* 20, 1840.

MUSEUM OF ECONOMIC GEOLOGY,

CRAIG'S COURT, CHARING CROSS, LONDON.

(Extract from the President's Address of the Geological Society of London.)

Among the most important of the remarkable events of the past year, we recognise with gratitude and confident anticipation of great advantage, both to science and the arts, the establishment by her Majesty's government of an institution hitherto unknown in England, namely, a Museum of Economic Geology. This is to be freely accessible to the public at stated periods, in the department of her Majesty's Woods and Forests, and Public Works, for the express object of exhibiting the practical application of geology to the useful purposes of life. In this Museum, a large store of valuable materials has already been collected and arranged, chiefly by the exertions, and under the direction of Mr. De la Beche. In it will be exhibited examples of metallic ores, ornamental marbles, building stones and limestones, granites, porphyries, slates, clays, marls, brick earths, and minerals of every kind produced in this country, that are of pecuniary value, and applicable to the arts of life. Information upon such subjects, thus readily and gratuitously accessible, will be of the utmost practical importance to the miner and the mechanic, the builder and the architect, the engineer, the whole mining interest, and the landed proprietors. The establishment will contain also examples of the results of metallurgic processes obtained from the furnace and the laboratory, with a collection of models of the most improved machinery, chiefly employed in mining. A well-stored laboratory is attached to this department, conducted by the distinguished analytical chemist, Mr. Richard Phillips, whose duty it already is, at a fixed and moderate charge, to conduct the analysis of metallic ores, and other minerals and soils submitted to him by the owners of mines and proprietors of land, who may wish for authentic information upon such matters.

The pupils in this laboratory are already actively employed in learning the arts of mineral analysis, and the various metallurgic processes.

A second department in the Economic Museum, will be assigned to the promotion of improvements in agriculture, and will contain sections of strata with specimens of soils, sub-soils, and of the rocks from the decomposition of which they have been produced.

To this last-mentioned collection, proprietors of land are solicited to contribute from their estates labelled examples of soils, with their respective sub-soils; and all persons who wish for an analysis of any sterile soil, for the purpose of giving it fertility, by the artificial addition of ingredients with which nature had not supplied it, may here obtain at a moderate cost, an exact knowledge of its composition, which may point out the corrective additions which it requires. This portion of the Museum will more especially exhibit the relations of geology to agriculture, in so far as a knowledge of the materials composing the sub-strata may afford extensive means of permanent improvement to the surface.—*Phil. Mag., October*, 1840.

St. James's Park.—An ornamental building in the Swiss style, consisting of a small room, bridge, and keeper's cottage, is now building in St. James's park for the Ornithological Society of London. The site is nearly opposite the Horse Guards, and the design, approved by the Board of Works, has been prepared by Mr. Watson, under whose direction it will be completed.

AN ACT FOR REGULATING RAILWAYS.

PASSED AUGUST 10, 1840.

No railway to be opened without notice to the Board of Trade.—Whereas it is expedient for the safety of the public to provide for the due supervision of railways: be it therefore enacted by the Queen's most excellent Majesty, by and with the advice and consent of the Lords spiritual and temporal, and Commons, in this present Parliament assembled, and by the authority of the same, that, after two months from the passing of this Act, no railway, or portion of any railway, shall be opened for the public conveyance of passengers or goods until one calendar month after notice in writing of the intention of opening the same shall have been given, by the Company to whom such railway shall belong, to the Lords of the Committee of Her Majesty's Privy Council appointed for trade and foreign plantations.

Penalty for opening railways without notice.—And be it enacted, that if any railway, or portion of any railway, shall be opened without due notice, as aforesaid, the Company to whom such railway shall belong shall forfeit to her Majesty the sum of 20*l.* for every day during which the same shall continue open, until the expiration of one calendar month after the Company shall have given the like notice as is herein-before required before the opening of the railway; and any such penalty may be recovered in any of her Majesty's courts of record.

Returns to be made by railway companies.—And be it enacted, that the lords of the said committee may order and direct every railway company to make up and deliver to them returns, according to a form to be provided by the lords of the said committee, of the aggregate traffic in passengers, according to the several classes, and of the aggregate traffic in cattle and goods respectively, on the said railway, as well as of all accidents which shall have occurred thereon, attended with personal injury, and also a table of all tolls, rates, and charges from time to time levied on each class passengers, and on cattle and goods conveyed on the said railway; and if the returns herein specified shall not be delivered within thirty days after the same shall have been required, every such company shall forfeit to her Majesty the sum of 20*l.* for every day during which the said company shall wilfully neglect to deliver the same; and every such penalty may be recovered in any of her Majesty's courts of record; provided always, that such returns shall be required, in like manner and at the same time, from all the said companies, unless the lords of the said committee shall specially exempt any of the said companies, and shall enter the grounds of such exemption in the minutes of their proceedings.

Penalty for making false returns.—And be it enacted, that every officer of any company who shall wilfully make any false return to the lords of the said committee shall be deemed guilty of a misdemeanor.

Board of trade may appoint persons to inspect railways.—And be it enacted, that it shall be lawful for the lords of the said committee, if and when they shall think fit, to authorize any *proper* person or persons to inspect any railway; and it shall be lawful for every person so authorized, at all reasonable times, upon producing his authority, if required, to enter upon and examine the said railway, and the stations, works, and buildings, and the engines and carriages belonging thereto: *provided always, that no person shall be eligible to the appointment as inspector as aforesaid who shall within one year of his appointment have been a director or have held any office of trust or profit under any railway company.*

Penalty on persons obstructing inspector.—And be it enacted, that every person wilfully obstructing any person, duly authorized as aforesaid, in the execution of his duty, shall, on conviction before a justice of the peace having jurisdiction in the place where the offence shall have been committed, forfeit and pay for every such offence any sum not exceeding 10*l.*; and on default of payment of any penalty so adjudged, immediately or within such time as the said justice of the peace shall appoint, the same justice, or any other justice having jurisdiction in the place where the offender shall be or reside, may commit the offender to prison for any period not exceeding three calendar months, such commitment to be determined on payment of the amount of the penalty; and every such penalty shall be returned to the next ensuing court of quarter sessions in the usual manner.

Copies of existing bye-laws to be laid before the board of trade: otherwise to be void.—And whereas many railway companies are or may hereafter be empowered by Act of Parliament to make bye-laws, orders, rules, or regulations, and to impose penalties for the enforcement thereof, upon persons other than the servants of the said companies, and it is expedient that such powers should be under proper control; be it enacted, that true copies of all such bye-laws, orders, rules, and regulations made under any such powers by every such company before the passing of this Act, certified in such manner as the lords of the said committee shall from time to time direct, shall, within two calendar months after the passing of this Act, be laid before the lords of the said committee; and that every such bye-law, order, rule, or regulation, not so laid before the lords of the said committee within the aforesaid period, shall, from and after that period, cease to have any force or effect, saving in so far as any penalty may have been then already incurred under the same.

No future bye-laws to be valid till two calendar months after they have been laid before the board of trade.—And be it enacted, that no such bye-law, order, rule, or regulation made under any such power, and which shall not be in force at the time of the passing of this act, and no order, rule, or regulation annulling any such existing bye-law, rule, order, or regulation which shall be made after the passing of this Act, shall have any force or effect until two calendar months after a true copy of such bye-law, order, rule, or regulation, certified as aforesaid, shall have been laid before the lords of the said committee, unless the lords of the said committee shall, before such period, signify their approbation thereof.

Board of trade may disallow bye-laws.—And be it enacted, that it shall be lawful for the lords of the said committee, at any time either before or after any bye-law, order, rule, or regulation shall have been laid before them as aforesaid shall have come into operation, to notify to the company who shall have made the same their disallowance thereof, and in case the same shall be in force at the time of such disallowance, the time at which the same shall cease to be in force; and no bye-law, order, rule, or regulation which shall be so disallowed shall have any force or effect whatsoever, or, if it shall be in force at the time of such disallowance, it shall cease to have any force or effect in the time limited in the notice of such disallowance, saving in so far as any penalty may have been then already incurred under the same.

Provisions of Railway Acts requiring confirmation of bye-laws repealed.—And be it enacted, that so much of every clause, provision, and enactment in any Act of Parliament heretofore passed as may require the approval or concurrence of any justice of the peace, court of quarter sessions, or other person or persons, other than members of the said companies, to give validity to any bye-laws, orders, rules, or regulations made by any such company, shall be repealed.

Board of trade may direct prosecutions to enforce provisions of Railway Act. Notice to be given to the company.—And be it enacted, that whenever it shall appear to the lords of the said committee that any of the provisions of the several Acts of Parliament regulating any of the said companies, or the provisions of this Act, have not been complied with on the part of any of the said companies, or any of their officers, and that it would be for the public advantage that the due performance of the same should be enforced, the lords of the said committee shall certify the same to her Majesty's attorney-general for England or Ireland, or to the lord advocate for Scotland, as the case may require; and thereupon the said attorney-general or lord advocate shall, by information, or by action, bill, plaint, suit at law or in equity, or other legal proceeding, as the case may require, proceed to recover such penalties and forfeitures, or otherwise to enforce the due performance of the said provisions, by such means as any person aggrieved by such non-compliance, or otherwise authorized to sue for such penalties, might employ under the provisions of the said acts: provided always, that no such certificate as aforesaid shall be given by the lords of the said committee until twenty-one days after they shall have given notice of their intention to give the same to the company against or in relation to whom they shall intend to give the same.

Prosecutions to be under sanction of board of trade, and within one year after the offence.—And be it enacted, that no legal proceedings shall be commenced under the authority of the lords of the said committee against any railway company for any offence against this act, or any of the several Acts of Parliament relating to railways, except upon such certificates of the lords of the said committee as aforesaid, and within one year after such offence shall have been committed.

Punishment of servants of railway companies guilty of misconduct.—And be it enacted, that it shall be lawful for any officer or agent of any railway company, or for any special constable duly appointed, and all such persons as they may call to their assistance, to seize and detain any engine-driver, guard, porter, or other servant in the employ of such company, who shall be found drunk while employed upon the railway, or commit any offence against any of the bye laws, rules, or regulations of such company, or shall wilfully, maliciously, or negligently do or omit to do any act whereby the life or limb of any person passing along, or being upon the railway belonging to such company, or the works thereof respectively, shall be, or might be injured or endangered, or whereby the passage of any of the engines, carriages, or trains shall be or might be obstructed or impeded, and to convey such engine-driver, guard, porter, or other servant so offending, or any person counselling, aiding, or assisting in such offence, with all convenient despatch, before some justice of the peace for the place within which such offence shall be committed, without any other warrant or authority than this act; and every such person so offending, and every person counselling, aiding, or assisting therein as aforesaid, shall, when convicted before such justice as aforesaid, (who is hereby authorised and required upon complaint to him made, upon oath, without information in writing, to take cognizance thereof, and to act summarily in the premises), in the discretion of justice, be imprisoned, with or without hard labour, for any term not exceeding two calendar months, or, in the like discretion of such justice, shall for every such offence forfeit to her Majesty any sum not exceeding 10*l.*, and in default of payment thereof shall be imprisoned, with or without hard labour as aforesaid, for such period, not exceeding two calendar months, as such justice shall appoint; such commitment to be determined on payment of the amount of the penalty; and every such penalty shall be returned to the next ensuing court of quarter sessions in the usual manner.

Justice of the peace empowered to send any case to be tried by the quarter sessions.—Provided always, and be it enacted, that (if upon the hearing of any such complaint he shall think fit) it shall be lawful for such justice, instead of deciding upon the matter of complaint summarily, to commit the person or persons charged with such offence for trial for the same at the quarter sessions for the county or place wherein such offence shall have been committed, and to order that any such person so committed shall be imprisoned and detained in any of her Majesty's gaols or houses of correction in the said county or place in the mean time, or to take bail for his appearance, with or without sureties, in his discretion; and every such person so offending, and convicted before such court of quarter sessions as aforesaid (which said court is hereby required to take cognizance of and hear and determine such complaint), shall be liable, in the discretion of such court, to be imprisoned, with or without hard labour, for any term not exceeding two years.

Punishment of persons obstructing railway.—And be it enacted, that from and after the passing of this Act every person who shall wilfully do or cause to be done any thing in such manner as to obstruct any engine or carriage using any railway, or to endanger the safety of persons conveyed in or upon the same, or shall aid or assist therein, shall be guilty of a misdemeanor, and being convicted thereof shall be liable, at the discretion of the court before which he shall have been convicted, to be imprisoned, with or without hard labour, for any term not exceeding two years.

For punishment of persons obstructing the officers of railway company, or trespassing upon any railway.—And be it enacted, that if any person shall wilfully obstruct or impede any officer or agent of any railway company in the execution of his duty upon any railway, or upon or in any of the stations or other works or premises connected therewith, or if any person shall wilfully trespass upon any railway, or any of the stations or other works or premises connected therewith, and shall refuse to quit the same upon request to him made by any officer or agent of the said company, every such person so offending, and all others aiding or assisting therein, shall and may be seized and detained by any such officer or agent, or any person whom he may call to his assistance, until such offender or offenders can be conveniently taken before some justice of the peace for the county or place wherein such offence shall be committed, and when convicted before such justice as aforesaid (who is hereby authorized and required, upon complaint to him upon oath, to take cognizance, thereof, and to act summarily in the premises,) shall, in the discretion of such justice, forfeit to her Majesty any sum not exceeding 5*l*, and in default of payment thereof shall or may be imprisoned for any term not exceeding two calendar months, such imprisonment to be determined on payment of the amount of the penalty.

Proceedings not to be quashed for want of form, or removed into the superior courts.—And be it enacted, that no proceedings to be had and taken in pursuance of this Act shall be quashed or vacated for want of form, or be removed by certiorari, or by any other writ or process whatsoever, into any of her Majesty's courts of record at Westminster or elsewhere, any law or statute to the contrary notwithstanding.

Repeal of all provisions in railway Acts that empower two justices to decide disputes respecting the proper places for openings in the ledges or flanches of railways.—And whereas many railway companies are bound, by the provisions of the Acts of Parliament by which they are incorporated or regulated, to make, at the expence of the owner or occupier of lands adjoining the railway, openings in the ledges or flanches thereof (except at certain places on such railway in the said Acts specified), for effecting communications between such railway and any collateral or branch railway to be laid down over such lands, and any disagreement or difference which shall arise as to the proper places for making any such openings in the ledges or flanches is by such Acts directed to be referred to the decision of any two justices of the peace within their respective jurisdictions: and whereas it is expedient that so much of every clause, provision, and enactment in any Act of Parliament heretofore passed, as gives to any justice or justices the power of hearing or deciding upon any such disagreement or difference as to the proper places for any such openings in the ledges or flanches of any railway, should be repealed; be it therefore enacted, that so much of every such clause, provision, and enactment as aforesaid shall be repealed.

Board of Trade to determine such disputes in future.—And be it enacted, that in case any disagreement or difference shall arise between any such owner or occupier, or other persons, and any railway company, as to the proper places for any such openings in the ledges or flanches of any railway (except at such places as aforesaid), for the purpose of such communication, then the same shall be left to the decision of the lords of the said committee, who are hereby empowered to hear and determine the same in such way as they shall think fit, and their determination shall be binding on all parties.

Communications to the board to be left at their office.—Communications by the board how to be authenticated. What shall be deemed good service on railway company.—And be it enacted, that all notices, returns, and other documents required by this Act to be given to or laid before the lords of the said committee shall be delivered to or sent by the post to the office of the lords of the said committee; and all notices, appointments, requisitions, certificates, or other documents in writing, signed by one of the secretaries of the said committee, or by some officer appointed for that purpose by the lords of the said committee, and purporting to be made by the lords of the said committee, shall, for the purposes of this Act, be deemed to have been made by the lords of the said committee; and service of the same upon any one or more of the directors of any railway company, or on the secretary or clerk of the said company, or by leaving the same with the clerk or officer at one of the stations belonging to the said company, shall be deemed good service upon the said company.

Meaning of the words "railway" and "company."—And be it enacted, that wherever the word "railway" is used in this Act it shall be construed to extend to all railways constructed under the powers of any Act of Parliament, and intended for the conveyance of passengers in or upon carriages drawn or impelled by the power of steam or by any other mechanical power; and wherever the word "company" is used in this Act it shall be construed to extend to and include the proprietors for the time being of any such railway, whether a body corporate or individuals, and their lessees, executors, administrators, and assigns, unless the subject or context be repugnant to such construction.

Act may be repealed this session.—And be it enacted, that this Act may be amended or repealed by any Act to be passed in the present Session of Parliament.

THE THAMES EMBANKMENT.

ABRIDGEMENT OF THE EVIDENCE.

(Concluded from p. 360.)

Mr. *Stephen Leach* stated, that he is clerk of the works on the river Thames, from Staines to Yantlet Creek; 39 years in all he has been in the service of the corporation: nine years assistant to his predecessor, and 30 years since. Very considerable improvements have taken place under his direction in the navigation of the Thames between Putney and Staines; when he came into the office, the navigation there was in a very bad state; it was no unusual thing for 50 or 60 barges to be aground in one place, and some of them he has known to be a fortnight working through the city jurisdiction. At present they get up with tolerable certainty, from the Pool to Staines, in 16 or 18 hours, and down from that place in less time; those improvements have been made under his direction. The improvements consist of the building of six pound-locks and five weirs, in different places, where the impediments were the greatest: the removal of a number of shoals, and the raising of towing-paths with the ballast so removed. He has considered the plan now before the Committee for embanking the river Thames from Vauxhall Bridge to London Bridge, on the north side; he considers it certainly as calculated to effect an indispensable improvement, by a very obvious and usual mode of improving river navigation, namely, by contraction; it is much too wide in several places to preserve a uniform depth, and a convenient one for navigation. The object of this embankment would be to equalize the section of the river, to regulate the velocity, and thereby to displace and enclose the large quantities of mud which are at present on the shores, and which receive the noxious contents of the sewers. The embankment begins at Vauxhall Bridge, where there is a short length, not very important. With regard to the navigation that joins from Vauxhall Bridge to Millbank, opposite the Penitentiary, there the embankment is complete, which is carried out to the full extent; there is no intention in that part of carrying it further out; he considers it as a specimen of what the embankment would be if it were continued in a similar way. The line is taken to the Horseferry-road. Horseferry-stairs, in front of the Marquess of Westminster's property: that would be a very beneficial improvement in his opinion. No part of that is embanked at present: the proposition is, to come flush with a very old wharf, which has been there for many years, now in the possession of Mr. Johnson, a stone wharf, a line with the embankment at the Parliament Houses, which completes it to Westminster Bridge; below Westminster Bridge the embankment is proposed to be continued to Scotland-yard; and there, on account of the particular nature of the business, and the number of coal barges, it is proposed to discontinue the embankment, and adopt a low embankment of some two or three feet above low water, so as to form a dock for the more convenient carrying and entering those barges; that is Mr. Walker's plan, and it is one in which he (Mr. Leach) quite concurs, according to the present occupation. From Scotland-yard, in front of the Hungerford Market estate, the York-buildings' estate, the Savoy, and so on, he thinks there is a length of about 1,400 feet, and an average width of about 300 feet; the mud on part of this ground is already so grown up as to have a pretty large vegetation upon it in front of York-buildings, already embanked with an accumulation of mud. From Waterloo Bridge the embankment is proposed to be continued in front of Somerset House and King's College, about 600 feet in length, and an average width of 130 feet; and at no place, in his opinion, is an embankment so much needed as in front of Somerset House, where there is a very lofty heavy pile of building immediately on the brink of the river, and he thinks it wants something to defend it in front of it, which would be a protection to the building; there is a depth of water in front of it, at the upper end of it particularly; the set of the current is immediately in that direction: that violent current has so deepened the water at Waterloo Bridge, that the late Sir Edward Banks recommended a deposit of about 3,000 tons of stone to protect the Bridge. From King's College the embankment proceeds about 460 feet in length, with an average width of about 190 feet to Water-street, from whence, the occupation of the wharfs being principally by coal merchants, the open-dock system of low wharfing is proposed; there must be an open dock there to accommodate the coal trade; then the embankment would be continued to the end of Temple Gardens; it is then intended to adopt the open-dock system and the low wharfing below the Temple, from Whitefriars-dock to Blackfriars Bridge. There is nothing particular between Blackfriars and Southwark Bridges, only to correct the present irregularities, and make a fair and straight line. It goes on to London Bridge; at the bridge it wants no contraction whatever, it is already quite small enough.

Mr. *James White Higgins* was examined; he is a surveyor of long standing; has been engaged both in the service of the Commissioners of Woods and Forests, and of the City of London, on very many occasions. The quantity of land to be embanked is 595,400 feet, that is, reclaimed by solid embankment; that I have from Mr. Walker's estimate, and that is independent of the Cro[illegible] property. The amount of Crown property is 436,150 feet. With re[illegible] is an exceedingly difficult question to deal with, and one not often occur; and as practice and experience are the best test of value, he has felt a good deal of difficulty in dealing with it. He has made it a matter of inquiry, and having had a great deal to do with wharf property, perhaps more than most professional persons he has endeavoured to bring the experience he possesses and the information he could gain to bear upon the subject; the conviction of his mind is, that 2*d.* a superficial foot, which was talked of, the property could not bear; he thinks it would be excessive; but he thinks 1*d.* a foot superficial might be borne, which would yield nearly 2,500*l.* per annum upon the solid embankment; he thinks so, as he has already stated, from the experience he has, from the advantages it is calculated to afford. It involves the improvement of the navigation of the river, which the persons using the wharfs would be benefited by; it gives them an increased quantity of freehold property; and with regard to that freehold property, if, as was done in a former case, he believes, and that to some considerable extent, at the time of building Blackfriars Bridge, the freehold property was made also free from rates and taxes, it would afford another advantage. That property so reclaimed at Blackfriars Bridge was charged at 1*d.* a foot, he finds; as far as he has been able to learn, it was found to work well; and one advantage that would be afforded here is, that in some cases persons with bad wharf walls would get good ones. In other cases, the general property would be secured by this embankment, and a great public highway, the Thames, would be benefited, and persons using it. Persons possessing themselves of freehold land, he thinks, would have no just ground of complaint in paying 1*d.* a foot for the property reclaimed; but there would be this difficulty about it, and one which the honourable Committee will feel perhaps to be considerable, a penny a foot on some portion of the property would be much too little, and on others it would be too much; in some cases persons would get the more valuable part of the property in Thames-street; he knows that they would be very glad to pay 2*d.* a foot; but in other cases he knows persons would not be willing to pay a penny per foot. The honourable member for Lambeth has alluded to cases in which the advantages now possessed by individuals would be lessened. Those points all want consideration. Every individual case, to do what he is quite sure the Committee are desirous to do, viz. to do justice, would require a matter of consideration; that is an affair which he has not entered upon except in this way, he has judged from his own experience. He has valued a good deal of wharf property; he has lately had to buy a good deal for the Crown at the enormous price that was invariably asked; we were then told that a few feet were worth nobody knows what money. He has also had to value with reference to a good deal of the parish assessments along the river, Hungerford Market and other parts; now he is quite satisfied that in some cases it would be an extraordinary boon at a penny per foot; but in others 1*d.* per foot could not be borne. How the separate cases are to be met he must leave to the Committee; but, in going from wharf to wharf, (he does not mean the Committee to understand that he has been on every wharf, he has been on many), he has put down what each wharf would bear, and that comes nearly to 1*d.* per foot, so that he feels warranted in saying that 2,500*l.* a year might be charged for the whole line of embankment, from one extremity to the other, where a solid embankment exists; but it is a matter of considerable difficulty. He has endeavoured to do it as honestly and impartially as he could, and bring all the experience which he has to the subject. Then as regards the dwarf piling, that is 725,700 feet; the superficial quantity enclosed by the dwarf piling, a halfpenny per foot has been talked of for that; he has more difficulty in this than in the other case, in saying what is right. There are advantages with reference to the navigation and security of buildings, and the possession of freehold instead of what, so far as he has heard of the evidence, appears to be a doubtful property, the city claiming a right over it, which would be abandoned, he takes it, in this case. But he has not, as in the case of Blackfriars Bridge, any test here, and after thinking of it a good deal, he has taken an annual sum for it of 1,133*l.*, that is, between a halfpenny and a farthing, the intermediate sum, as an annual sum; a halfpenny per foot was mentioned; he thought it too much, for it gave larger rent in some places than it appeared to me they could bear, though they have advantages in this case; by becoming their own freehold they would have a right to embank at any future period; but it is a matter of so much difficulty, that to give his evidence as he could upon some subjects, to say that he knows from experience that the property would produce such results, he could not pretend to do. It is open to much doubt. His impression is, that in both cases he has been moderate; he intended to be so. It would be worth to sell, twenty-five years' purchase. He would not be warranted in putting it at 25 years' purchase unless it was connected with the other portions of the property. Freehold land connected with buildings is generally at 20 years' purchase only. A ground-rent, amply secured, has sold for 30 or 31 years' purchase. This is an intermediate case of 25 years' purchase. He thinks 30 years would be too much, as there is some speculation in it, or else it is a ground-rent, and therefore he thought 25 was safer.

The following is the Report of Mr. Walker made in 1821, referred to in his evidence given in the last month's Journal.

"From the recent, and, we believe, accurate surveys that have been made, it appears that the difference of level in the water above and below bridge, towards the latter end of the ebb of a spring tide, is from 4 feet 4 inches to 5 feet 7 inches; the water is therefore at present dammed up to that extent at the bridge; we find, by calculation, that this pen will be reduced from, say 5 feet, to about 3 inches, by the proposed alterations; and the water above bridge, at low water, will therefore be 4 feet 9 inches lower than at present. But as the velocity of the stream above bridge will be increased by a greater quantity of water having to run through in the same time, both on account of the water flowing higher at high water, and ebbing lower at low water, the inclination of the surface will also be increased; and this lowering of 4 feet 9 inches, above referred to, will decrease as the distance from the bridge increases. Now, by the survey above referred to, the present rise in the surface of the water from London Bridge to Westminster Bridge, at low water, is 12 inches, being 6 inches, per mile; and supposing the velocity, after the alterations, to be increased so as to produce twice the inclination, or 12 inche.. , the surface of the water at Westminster Bridge will be lowered, at low water, 4 feet 9 inches, less one foot (the increase of fall), or 3 feet 9 inches below its present level at spring tides. Again, from the best information we can collect, the rise of surface from Westminster to Fulham is about 8 inches per mile; and as the effect of the alterations of London Bridge will be less sensibly felt here than nearer the bridge, we assume that the inclination, after the alterations, will be 12 inches per mile, and the distance being nearly 6 miles, the water at Fulham will be lowered at low water 3 feet 9 inches less 2 feet, or 1 foot 9 inches, which will increase as we descend towards West- ... idge, when (as before stated) the depression will be 3 feet 9 inches. ... at Fulham, the surface will be lowered 1 foot 9 inches, this depression will decrease upwards; but as in any given length upwards, the effect of the proposed alterations will also decrease, this depth (1 foot 9 inches) will be felt a considerable way up the river; for we think it probable that the effect of the alterations may be sensible, in point of the navigation, for 6 miles above Fulham Bridge, or at Kew Bridge; and that though it will really extend higher, we apprehend that its effects will not be of any consequence above that point. We believe there is no speculation in any of the above numbers, excepting in the assumed increase of declination of surface; for the correctness of which we cannot vouch, but we have been guided by the consideration that 4 feet 9 inches at low water, and about 9 inches at high water, making together 5 feet 6 inches, will be added to the depth of water which will pass through the bridge at every spring tide; and by allowing an increase of fall in proportion to the square of the increase of velocity or quantity, and also by referring to the inclination in the upper part of the river, say between Mortlake and Teddington, as shown upon Mr. Whitworth's survey, and making such allowance as from the difference of situation appeared to us reasonable, we apprehend that we are not far from being correct, particularly between Fulham and London Bridge; and it is hardly necessary, after the above, to say that we agree in opinion with Mr. Smeaton, that, by this reduction of fall at the bridge, 'the navigation of that part of the river will be materially affected.' It appears to us, from our own knowledge, and from the statements that have been given to us, that although the increased velocity of the river would have a tendency to restore the river to its ancient depth, and in course of time would probably effect that object, yet that so great a lowering at once would be productive of great temporary inconvenience, unless artificial means were resorted to, to deepen the shoals, which, even in the present state of the river, are attended with considerable hindrance to the navigation. Mr. Smeaton's opinion on this subject goes beyond our ideas of time; but, as great respect is due to his opinion, we extract it in his own words: 'If this difference of bed,' that is, the difference above and below bridge, 'is original, we must expect it to remain after the bridge is taken away; but if an effect, the cause being removed, the river would gradually restore itself; but as this might probably take up 700 or 800 years (the time it has probably been gathering), the work of restitution would go on far too slowly to answer the demands of the present generation.' Our opinion is, that the difference of level in the bottom of the river, above and below bridge, is caused, in a great measure, by the pen of the bridge; and although we think that the work of restitution would be complete in less time than stated by Mr. Smeaton, unless where the accumulation has got cemented into a solid mass, which we have no doubt is in many places the case, yet, both for the purposes of present trade, and to prevent the shoals from being moved down the river by the current, and forming obstructions lower down the river or below bridge, we think that ballasting to a great extent will be expedient and requisite; as, in addition to the above reason, the stuff that is excavated from the upper part may be applied to raise the towing-paths and banks, so as to meet the increased height of the high water, which will occasionally be from 1 to 2 feet above the present level. One principal shoal is close above London Bridge, on the Surrey side; it extends almost half-way across the river, and is even now occasionally above low water. This must therefore be deepened to a considerable extent; and to prevent the opening of any of the proposed widened arches, which will be opposite to it, from washing any part of it into the Pool, and settling upon the shoals below bridge, it, as well as the other shoals, ought to be ballasted away before the proposed arches are opened. In regard to the navigation through London Bridge, we are of opinion that it will be very essentially improved by the proposed alterations, and that the cause of the losses, accidents, and dangers to which the passage is at present subject, from the great fall or shoot in the arches, will be almost entirely removed. We have mentioned, that the velocity of the current above bridge will be increased. This will take place during both the flood and ebb tide, but will be greatest in the latter; and the increase of velocity will, as before stated, be greatest between Westminster and London Bridges. In our calculation of the fall, we have supposed that the increase of velocity will amount to one-half of the present velocity. This will, in many cases, be important, not only as regards the velocity itself, (as to which it will sometimes be found of advantage to craft and sometimes probably otherwise), but as the water will ebb sooner from all the wharfs, the time in each tide during which the barges are afloat at the wharfs and when they can float to and from them, will be decreased. This will, so far, be a disadvantage, but will occur only during the ebb of tide. It is evident, however, that it will not be compensated by the increased velocity of the flood-tide bringing the barges sooner to the wharfs above bridge, as the velocity of the flood will not be so much increased as that of the ebb-tide, and although barges may come up opposite to the wharfs sooner in the tide than they do at present if the channel is deep enough, they will not be able to get close to the wharfs until about the same time of tide they do at present, unless a general artificial deepening takes place opposite to each wharf. In some cases, however, barges which may get opposite to the wharfs early in the tide, will be enabled by having done so to draw in to the wharfs so soon as there is depth enough of water to float them in, and, so far as this goes, the effect of this proposed alteration will be useful. The great cause of shoals is the unequal velocity of currents, and this inequality increases as the velocity increases; for therefore it is that floods, or great velocities, are always found to add to the shoals of navigable rivers, and to deepen what was too deep before. The increased current through the narrow parts disturbs and carries down the materials of the bottom through those narrow parts or deeps, and they are lodged ...

the shoals below, where the decreased velocity, caused by the widening of the river, has not force enough to carry them along with it. There can be no more striking illustration of this general theory, than the effect of floods upon the river near London Bridge, which is invariably to deepen between the arches, and at the same time to raise the shoals below the bridge: therefore, although the natural effect of the increase of current is upon the whole to deepen its channel, it does it so partially that it has also the effect, in rivers of unequal current, such as the Thames is, of forming and increasing shoals, and unless guarded against by proper means may therefore be injurious to the navigation. Now the effect of opening London Bridge will be, that the ebb-tide and land-floods, not being checked by the pen of London Bridge, will increase in velocity to the extent *up the river* that the effects of this pen are felt, and produce the consequences we have mentioned, so that an increase of expense in deepening the shoals after floods, and a greater inequality of level in the bottom, will be the consequence, and this will be a lasting expense unless means are taken to prevent it. The means we should recommend are, the nearer approximation to an *uniform velocity*, which would best be accomplished by producing an *equality of area*, such as contracting the *width* of the river abreast of the shoals, *by means of embankments or otherwise*: as this cannot, however, be done in many places to the required extent without enormous expense, ballasting must be had recourse to until a new regimen corresponding to the existing circumstances is obtained. Finally, although we think it might have been desirable that the great change, which the proposed opening of the arches in London Bridge will certainly produce in the navigation, had been made, so that their effects might have been felt, and things conformed to the new state by degrees, yet when called upon to give an opinion without these experiments, we feel little hesitation in saying that if effectual means are taken for preventing the evils to which we have referred, then the proposed alterations will be beneficial to the navigation above bridge, but that without those effectual means they will be injurious."

Now, the fact is, that the alterations have been made to the full extent stated in this report, and the consequences have been to the full extent of what is stated, but as yet no means have been taken to remove the evil which was anticipated, and is now felt.

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

INSTITUTION OF CIVIL ENGINEERS.

April 14.—The President in the Chair.

"*Description of a Dynamometer, or an Instrument for measuring the Friction on Roads, Railways, Canals, &c.*" By Henry Carr, Grad. Inst. C. E.

The object of Mr. Carr's modification of the dynamometer is to obviate the irregularity of the common indicator arm, caused by the jerking motion of the tractive power or any inequality of resistance. The instrument consists of a cylinder half filled with mercury, and containing a piston connected with the spring of the dynamometer, so as to be lowered or raised as the tractive power is increased or diminished. Two tubes of glass, connected by a passage with a regulating valve, stand in front of the cylinder, one of them communicating freely with it, and in this tube the mercury is raised or lowered proportionally to the power applied; while in the other, an average of the variations is obtained as the facility of communication between the tubes is increased or diminished by the opening or closing of the stop-valve. The instrument must be graduated by actual experiment, and the results of the average power may be read off from the scales placed behind the tubes. The paper is illustrated by a detailed drawing of the machine.

"*An account of a proposed Suspension Bridge over the Haslar Lake at Portsmouth.*" By Andrew Burn, Jun., Grad. Inst. C. E.

The usual calculation for the maximum load on each superficial foot of the platforms of suspension bridges is 70 lb.; but, as in the event of a crowd of persons assembling the pressure may increase to nearly 100 lb. per foot, and by the passage of soldiers marching in regular time the strain may be greatly augmented, the projector assumed 200 lb. per superficial foot as the amount of load to which the platform might be subjected. The peculiar feature of this bridge is the substitution of cast-iron chains for the wrought-iron ones generally used. This deviation from the usual practice is adopted as a measure of economy, and with a view of increasing their stability and durability, cast-iron being much less influenced by atmospheric action than wrought-iron. Cast-iron beams, when well proportioned, will bear a very considerable tensile strain. As these chains would be proved beyond the weight they are intended to bear, no doubt is entertained by the author of their security. The platform, which is formed of transverse iron girders carrying cast-iron plates ⅜ of an inch thick, with dovetails falling into holes cast in the girders, is suspended by wrought-iron rods 1¼ inch square from two lines of chain only, as the strain is more easily brought to bear on them than on a greater number of chains. They are trussed laterally to prevent oscillation, and the balustrade is so constructed as to prevent the undulation so prejudicial to suspension bridges generally. To insure a perfect bearing, each pair of links of the chains are in manufacturing cramped together, and the holes bored out to receive the pins which are turned to fit them accurately; they are of a larger size than usual, being 4 inches diameter, and a less number are employed. The piers on which the chains pass are of cast-iron, 33 feet high above the level of the roadway.

		Feet.
The extreme length of the bridge is	. . . .	632
The breadth of the roadway	. . . . .	17½
The clear waterway between the piers	. . .	300
The clear headway of the platform above the high water line	. . . .	18½
Ditto ditto above low water line	. .	33

The tension on the chains is calculated as equal to 991·4143 tons. To sustain this tension, the section of the chains is 256 square inches, and taking 7 tons per square inch as the elastic limit of cast-iron, the resistance of the chains will equal 1792 tons, leaving a surplus of 800·6 tons after the calculated strain has been deducted from the real strength of the chains. Three elaborate detailed drawings accompany this paper.

Mr. Smith, of Deanston, *explained a new system of Lockage for Canals proposed by him, a model of which he presented to the Institution.*

To avoid the present expensive construction of locks and their waste of water, the author proposes to divide the canal into a series of basins, the water levels of which should be from 12 to 18 inches above each other. The extremity of each basin is so contracted as to permit only the free passage of a boat; in this is placed a single gate, hinged to a sill across the bottom, the head pointing at a given angle against the stream, and the lateral faces pressing against rabbets in the masonry. The gate is to be constructed of buoyant materials, or made hollow so as to float and be held up by the pressure of the water in the higher level; on the top is a roller to facilitate the passage of the boats. When a boat is required to pass from a higher to a lower level, the bow end, which must be armed with an inclined projection, depresses the gate as much as the depth of the immersion of the boat, and as much water escapes as can pass between its sides and the walls of the contracted part of the basin. The same action takes place in ascending, except that a certain amount of power must be expended to enable the boat to surmount the difference of level between the basins. The quantity of water wasted by each boat would be in proportion to its immersion and the speed at which it passed over the gate. In case of different sized boats passing along the same canal, it is proposed to have a small gate forming part of the main gate, so as to avoid the loss of water which would ensue from the whole width being open for the passage of a small boat.

This system has only been tried by models; but it is proposed to make an essay on an extensive canal next summer, when the results will be communicated to the Institution.

May 5.—The PRESIDENT in the Chair.

The following were balloted for and elected:—Angier March Perkins, St. George Burke, and Beriah Botfield, as Associates.

"*Description of the Engines on board the Iron Steam Tug, the Alice.*" By J. Patrick, Inst. C. E.

The speed of this boat having far exceeded the constructor's expectations, induced the author to send a description of her proportions, and of the construction of the engines. The chief peculiarity in the engines is their being placed in the centre of the vessel, with the two cylinders in a line with the keel, and placed at an angle of 45°, inclining inwards towards the paddle shaft, to which the motion is communicated direct (without the use of side beams) by long connecting rods attached to the cross heads, which are placed at the lower ends of the cylinders, instead of being on the top as in the usual manner; the connecting rods are thus enabled to be three times instead of twice the length of the stroke, as is usually the case. The framing is entirely of wrought-iron on the tension principle, and appears to resist the tendency to vibration better than cast-iron framing. For the two cylinders of 31 inches diameter, there is only one air pump of 22½ inches diameter, with 19½ inches length of stroke, instead of the usual complement of two air pumps, 18 inches diameter each; this is found to be sufficient, as a vacuum of 13¾ lb. per square inch is maintained. One of the advantages proposed by this mode of construction is the reduction of weight; these engines only weighing 9 cwt. per horse power. The small space occupied leaving more room for passengers, they are particularly adapted for river navigation, where the breadth of beam must be limited. The simplicity of their construction renders them less liable to expensive repairs.

The principal proportions of the Alice are—

	Feet.	Inches.
Length between perpendiculars	95	
Breadth of beam	20	
Draft of water	4	6
Diameter of wheel	14	
Size of engines	two 30 horse power	
Diameter of cylinder	0	31 inches
Length of stroke	3	3

The engines were constructed by Messrs. Davenport and Grindrod, of Liverpool. Drawings of the boat and engines accompany this communication.

"*Description of an Apparatus for preventing the Explosion of Steam Boilers.*" By Robert M'Ewen.

The frequent explosions of steam boilers, caused in many instances by the steam being confined until it acquires a density greater than the boiler can resist, induced the author to invent a simple, self-acting apparatus, intended to warn the engineer whenever the pressure exceeded the proper degree of safety.

The apparatus under consideration is constructed on the principle that steam, in proportion to its density, will support a column of water or mercury, of a given height, and that any fluid will find the same level in two or more vessels, provided there be a free communication between them. It may be called a mercurial safety valve, and consists of a cylinder, within which are two cups, with two pipes dipping into them of a length proportioned to the pressure of the steam; these pipes are connected at the top with two valves on one spindle, so arranged, as that when one is open the other must be closed. On the top is a waste steam pipe open to the atmosphere. One pipe being filled with mercury, and the valve connected with it being open, the mercury remains stationary until the pressure of the steam exceeds its proper point. It will then be blown out and fall into the empty cup, allowing the steam to escape by the waste pipe, and giving warning to the engineer by its noise. When the pressure is again reduced to its proper point the valve is reversed, and the mercury will, on the next occasion of an increase of pressure, be blown back again, still giving warning on either side.

Plans and sections of this apparatus accompanied the paper.

"*On setting out Railway Curves.*" By Charles Bourns, Assoc. Inst. C. E.

Mr. Bourns having been engaged in setting out the Taff Vale Railway through a country presenting circumstances of more than ordinary difficulty, which rendered it necessary to vary the radii and the flexure of the curves frequently, his attention was particularly directed to the subject; and he has treated it in this paper clearly and successfully, demonstrating the several cases geometrically, and generally in a plain and satisfactory manner. He calls attention to the inaccuracy of applying a square to the setting out of segmental curves, particularly those of short radii, and recommends an offset staff as theoretically correct and practically much more convenient. The general rule to find the offset is—"Divide the number of inches in the chain used by the number of such chains in the radius of the required curve, the quotient is the offset in inches." The paper is accompanied by a table of offsets for curves of different radii; which the author found extremely convenient for use in the field.

The paper being altogether mathematical is not adapted for publication in abstract; but it will be given at length, with examples and diagrams, in the Transactions of the Institution.

"*Description of an Instrument for describing the Profile of Roads.*" By Henry Carr, Grad. Inst. C. E.

The object of the author was the construction of a machine, which, being drawn along any road of moderately even surface, should describe the section of the line over which it passed. It is evident, that if a pendulum be suspended from a frame standing perpendicularly when the machine rests on a horizontal plane, on passing over a plane inclined at any angle with the horizon, the pendulum must form the same angle with the frame the tangent of which angle in terms of the radius will be the rise or fall of the plane. The duration of the tangent will be determined by the paper on which the section is drawn being made to traverse at a speed proportionate to the distance passed over; and the extent, by the difference of the speeds of a nut and screw which are made to revolve in the same direction—the nut turning at a constant velocity, and the screw at a speed differing from that of the nut in proportion to the tangent, slower or faster as the tangent is *plus* or *minus*, raising or lowering the nut according to the deviation of the plane from the horizontal line.

The machinery is set in motion by the wheels of the carriage, and a series of wheels and pinions of given diameters cause the ground line and datum line to be drawn simultaneously by two pencils on a paper which gradually unfolds itself from one drum, and is transfered to another at the rate of 16 inches per mile passed over, or on a scale of 5 chains to the inch. A profile of a line of country may thus be obtained with sufficient accuracy for a preliminary survey.

A comprehensive perspective drawing accompanies the paper, and explains the construction of the machine.

May 12.—The PRESIDENT in the Chair.

"*Photography, as applicable to Engineering.*" By Alexander Gordon, M. Inst. C. E.

The object of the author in this paper is to direct general attention to the advantages which may be expected to result to the profession of the Civil Engineer from the discoveries of Mons. Daguerre and others, in enabling copies of drawings, or views of buildings, works, or even of machinery when not in motion, to be taken with perfect accuracy in a very short space of time and with comparatively small expense. This system of copying not only the outline, but the tints of light and shade, united with accurate linear perspective, he contends may be easily adapted to the purpose of the engineer, as well as to all those professions in which the art of drawing is used. The photographic apparatus has already been employed to bring before us exact copies of the most interesting monuments of antiquity, the French antiquarians and artists having found it more easy and correct to Daguerreotype the Egyptian monuments and decipher the hieroglyphics at their leisure, than to labour over the originals.

The subject is divided into two branches: the first being the art of copying drawings and plans by the transmission and absorption of light by prepared paper. The drawing to be copied is placed between two pieces of plate glass, held down in close contact with a sheet of photogenic paper, prepared by being washed over on both sides with a neutral solution of nitrate of silver of a spectfic gravity of 1·066, and afterwards with a solution of common salt and water (1lb. of salt to 25 pints of water). The paper thus prepared must be dried and kept in the dark, on account of its peculiar delicacy. The rays of the sun are then permitted to pass through the white portions of the drawing or print, while they are interrupted by the black lines, and more or less by the tinted portions. The rays of light thus act upon the prepared paper, and produce, in a few minutes, a reversed copy, reproducing the lights of the original in shadows; this can be remedied by taking a second copy from the first, and thus the shadows are restored to their original positions. To destroy the sensitiveness of the prepared paper, and preserve the copy, it is soaked in pure water, which carries off the excess of nitrate of silver, then covered with a solution of hypo-sulphite of soda of a specific gravity of 1,055, and again washed in pure water, so that when dried it is permanently fixed. It is evident that a copy thus obtained must be exactly like the original, and the value of such a process may be readily estimated by engineers.

The second branch, which is named "Daguerreotype," after the distinguished artist who brought it to its present state of perfection, is of a much higher order. This is the art of fixing and preserving on the surface of a polished silvered plate the images collected in the focal plane of a camera obscura.

The process is rather complicated, but may be thus briefly described. The surface of the silvered plate being cleaned and polished very perfectly by means of finely levigated pumice stone, olive oil, and cotton, is rubbed lightly over with diluted nitric acid, in the proportion of 1 pint of acid to

16 pints of distilled water; it is then subjected to the heat of charcoal or a spirit lamp until a firm white coating is formed all over the surface of the silver. The plate is then suddenly cooled. This process is repeated three times. It is placed in a dark chamber with the face or silver surface downwards, where it is acted upon by the spontaneous evaporation of iodine; this condenses upon the silver, and produces a fine gold-coloured surface, extremely sensitive to the impressions of light. It is then placed in a camera obscura, the light having been until then perfectly excluded from it. It there receives the impression of any images brought within the focal plane; and by subsequently exposing it in a dark, close chamber, with its silver surface downwards, to the fumes of heated mercury, the images are rendered visible; to fix the images so received, the iodine is removed by dipping the plate in pure water, and then washing it either with a weak solution of hypo-sulphite of soda or a saturated solution of common salt, and finally dipping it in distilled water and drying it. It should then be framed and glazed to preserve it from external injury, and the picture will remain unchanged.

Attempts have been made to use this process for preparing the plates for engravers, as much time and cost would thereby be saved, but hitherto it has not been done to any extent.

The author presses upon the Institution the applicability of these processes to engineering uses, and quotes the remark of Mons. Arago—"That photographic delineations having been subjected during their formation to the rules of geometry, we may be enabled, by the aid of a few simple data, to ascertain the exact dimensions of the most elevated parts of the most inaccessible edifices."

Mr. Cooper, Senior, introduced the subject of photography by explaining, and illustrating by instruments and diagrams, the principles of the division and dispersion of the rays of light, according to the Newtonian theory, as well as the most recent researches into the subject. He described the chemical properties of light—its affinity for certain combinations, such as chloride of silver—its heating powers—the different effects of the rays on vegetation—and the application of these known principles to photography. He then explained the chemical properties of the chloride of silver, iodine, and other substances used in the process. In alluding to the probable uses of the Daguerreotype, he observed that the process might be employed to make drawings of machinery, as graduated scales might be fixed to certain parts of the objects, and they would be copied in their relative proportions to the machine.

Mr. Cooper, Junior, illustrated Mr. Gordon's communication by explaining the photographic apparatus, and the process of obtaining a specimen of Daguerreotype by means of the oxy-hydrogen light. He described, among other points, the difficulty of obtaining pure silver upon the copper plates, as, for the advantage in rolling, the manufacturer will introduce an alloy of ½ to 1½ per cent. On this account, acid is used so repeatedly in cleaning the plates, that any particles of copper which have been rolled into the surface may be carried off. He explained his improvement to the iodine box, which consists in spreading the iodine all over the bottom of a tray lined with glass, and covering it with a piece of card-board, which becomes saturated with the fumes of the iodine, and on the silvered plate being placed over it, acts equally over its surface, instead of partially, as in the old system of placing the iodine in a mass in the centre of the tray. He had found this to be a great improvement. The shortest time in which he had obtained a photographic picture in England was 11 minutes: while, during a gloomy day in November, it took an hour and a half to procure a moderately good one.

"*An Universal Screw-Jack.*" By George England.

This machine, a model of which was presented to the Institution, is intended for raising heavy weights and moving them in any required direction; the vertical motion is similar to that of a common screw-lifting jack, and the lateral motion is communicated by a ratchet lever to a horizontal screw, working in bearings on a strong cast-iron bed with planed surfaces through a double nut attached to the base of the jack. The jack has been found useful for erecting heavy pieces of machinery, and for replacing railway carriages and locomotives on the rails when they have been accidentally thrown off.

"*Description of a Traversing Screw-Jack.*" By W. J. Curtis.

The screw-jack is attached to a plank with a rack in it, and slides in a groove in another plank which is placed beneath it, across the railway; in the lower plank is a rack, by means of which and a hooked lever, the jack, with the engine or any other weight resting upon it, is drawn easily across the rails and lowered to its proper position. By this apparatus, engines and carriages of considerable weight have been replaced on a railway by two men in a very short space of time.

A model of the machine was presented to the Institution.

May 19.—The President in the Chair.

Peter Bruff was balloted for and elected an Associate.

"*Description of a new Gas Regulator.*" By James Milne.

The object of this instrument (which the inventor exhibited in action, and presented to the Institution) is to regulate the supply of gas to burners, so that any variation in the pressure, arising from extinguishing the adjacent lights along the line of the street main, or in the different floors of manufactories, shall not affect those lights which are supplied through the regulator.

The regulator consists of a cylindrical outer case, to which is affixed a water gauge to show the pressure; to the top is attached an inner cylinder, open at the lower end and reaching nearly to the bottom of the outer case; the gas is introduced from beneath by a tube in the centre, terminating in a conical valve at the top; the male part of the valve is fixed by three arms to the top of a float, which moves freely in the space between the inner cylinder and the centre tube; the areas between the outer case and the inner cylinder, and between the inner cylinder and the centre tube, being alike, the pressure of the gas acts upon the water within the inner cylinder, and causes it to rise in the outer case just as much as it is depressed in the inner space. This depression carries down the float with the male part of the valve attached to it, and thus diminishes the aperture of the supply pipe, until the pressure is relieved by other burners being lighted, and enables the supply of gas to be in proportion to the demand. The pressure may be regulated at will by increasing or diminishing the quantity of water in the cylinders, and it is shown correctly by the graduated glass gauge. This apparatus has been found, in an experience of two years, to effect a saving of about 20 per cent., independent of its ensuring a perfect equality to all the burners in action. Drawings of the instrument accompanied this communication.

Mr Lowe believed the "gas regulator" to be an efficient instrument. It was of the utmost importance that the light from gas should be steady and equal, as the nerves of the eye were more injured by an unsteady than by an intense light. In large establishments, the greatest care would scarcely prevent constant variation in the lights, so that an efficient means of producing regularity must be valuable.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

Tenth Meeting.—*September*, 1840.

(From the Athenæum.)

Section G.—Mechanical Science.

Mr. Dircks gave an account of *a railway wheel with wood tyre*, which was exhibited in the museum. It was one of a set which had been in use for two months, carrying five tons each day. The construction of the wheel will be understood by imagining an ordinary spoked wheel, but with a deep-*channelled* tyre. In this channel is inserted blocks of African oak, measuring about 4 × 3½ inches, prepared by filling the pores with such unctious preparations as counteract the effects of capillary attraction in regard to wet or damp. The blocks are cut so as to fit very exactly, with the grain placed vertically throughout, forming a kind of wooden tyre. There are about thirty blocks of wood round each wheel, where they are retained in their places by bolts, the two sides of the channel having corresponding holes drilled through them for this purpose; each block of wood is thus fastened by one or two bolts, which are afterwards well rivetted. After being so fitted, the wheel is put into a lathe, and turned in the ordinary manner of turning iron tyres, when it acquires all the appearance of a common railway wheel, but with an outer wooden rim, and the flange only of iron. Mr. Dircks proposes the use of either hard or soft woods, and of various chemical preparations to prevent the admission of water into the pores of the wood: he also contemplates the using of wood well compressed.

Mr. Jeffrey *on a New Hydraulic Apparatus.*—It comprised an improvement on the ancient endless chain of buckets, which he considers of Egyptian origin. This apparatus has hitherto never acquired the value it admits of, on account of a defect having remained in its construction, opposed to geometrical principle—the buckets which bring up the water being fixed outside instead of within the rope. The effect of this is such an acceleration of the bucket, when it is carried round the wheel at top, as causes it to overtake the water and carry much of it down again. But, by placing the buckets on the centre side of the ropes, that is, within them, the bucket when passing round the wheel, being very near the centre, is much retarded, and the momentum of the water causes it to ride out of the bucket very effectually into the trough. A peculiarity in the form of the bucket also prevents the spilling of the water in cases where the motion is very slow.

Sir J. Robison stated that, although the methods in India are rude, yet they give a greater return of work done for power applied than other methods known.—Mr. Jeffrey stated that he had tried this method on a large scale, each bucket containing 1½ cwt. of water. A small valve at the bottom of the bucket allows the air to enter, and the bucket is thus quickly emptied.

"*Additional Notice concerning the most economical and effective proportion of Engine Power to the tonnage of the hull in Steam Vessels, and more especially in those designed for long voyages.*" By Mr. Scott Russell

Large power or small power? has always been a disputed question. The early steam boat engines had but a small power proportioned to the tonnage. The *Comet* had 25 tons burden, and only three horses power—being a proportion of power to tonnage amounting to ⅛. On this subject modern practice and opinion seem to offer no guide. The East India Company have used low proportions of power to tonnage, and in this they appear to have adopted the general maxims of Southern engineers. The Government appear also to have followed the same course, but without going to the same extreme. The Clyde engineers adopt the opposite maxim, and place as much power in their vessels as can be conveniently applied. There appears at present to be a feeling in favour of a high proportion of power to tonnage. It has been found by some of the best mercantile companies that a high proportion of power to tonnage is not only better for expedition, but also more economical of fuel and of capital; and instances are frequent of an increase in the power of a steam vessel, producing a diminution in the consumption of fuel. As this question is becoming every day of greater importance, it is proper to examine it carefully. In the first place, it is known that the proportion of power must be very much increased to gain a given increase of speed;—thus, if ten horses power propel a vessel through water five mile an hours, it will require forty horses power to propel the same vessel ten miles an hour; since it will require a quadruple power to obtain a double speed, in like manner it will require a ninefold power to triple the speed. A large power of engine, it may be said, occupies much useful space which might be filled with cargo. It consumes much coal, and the speed is by no means proportioned to the expense of fuel and machinery. But this is a limited view of the subject. If time, as an element, and a very important one in the value of mercantile conveyance, be calculated, then it will be found that in many cases the effects of high speed, at any expense of fuel, will compensate for that expense. But it is not on the value of speed at the present day that we proceed in this inquiry. We are to ascertain what may be the best proportion of power to tonnage in sea-going vessels. We have seen that the lowest speed is the most economical, and that it requires expensive additions to give high velocities. But in arriving at this conclusion, we have taken only the case of smooth water: here it is obvious that the smallest power will be most economical. But it should be remembered that the great purposes of steam are generally of a different nature from the mere generation of motion through a quiescent fluid. The force of adverse winds, waves, and tides are to be overcome,—and it is the success of steam in obtaining regularity and speed, in spite of these, which constitutes its superiority. Now, if we take a simple case of one of these, we shall soon find that a higher proportion of power to tonnage may be essential not only to speed but even to economy. Suppose, a steam-boat with a small proportion of power, capable of propelling the vessel at the velocity of three miles an hour through still water, to be applied to stem a current of three miles an hour, or a proportionately strong breeze,—is it not plain that the vessel would make no headway? This extreme case of too little power shows that there is at least one proportion of power which is too small for economy of fuel. We may now proceed to investigate the question of best proportion, or the point where the attainment of high speed is accompanied by absolute saving of fuel, as compared to lower velocity. For this purpose we merely take it for granted, that the speed through the water will be nearly as the square root of the former, according to the general law of the resistance of fluids; that the resistance offered by adverse winds, &c. has been ascertained, and is determined on a particular station, that is, that it is known that on a given station, a given vessel, with a given power, makes a voyage in adverse circumstances in, suppose, double the time of her most prosperous voyage, say her prosperous voyage in fourteen, and her adverse voyage in twenty-four days, being a retarding power of ten days out of twenty-four; we take this retardation of ten days as the measure of the retarding power of adverse weather in the given circumstances. By working out the result, we obtain the very simple rule for finding the best proportion of power to tonnage: from the square of the velocity of any given vessel in good weather, subtract the square of the velocity of the same vessel in the worst weather, divide the difference by the square of the velocity in good weather, and the quotient multiplied into double the horses' power of the said vessel, will give the power which would propel the same vessel in the same circumstances, with the smallest quantity of fuel. It further appears, that the consumption of fuel in the worst voyage, will not exceed that of the best voyage, in a greater proportion than 10 to 7—that is to say, for 70 tons of fuel burnt on a good voyage, it will not be necessary to carry more than 100 tons, in order to provide against the worst. Let us take, as example, a Transatlantic steam-ship, which has a proportion of 1 horse power to 4 tons of capacity; her unfavourable voyage being, between England and America, twenty-two days, and her favourable voyage fourteen days, being a comparative velocity 7 and 11.

$$\text{Then } h' = 2\,h'\,\frac{v^2 - v'^2}{v^2} = 2.\ \frac{121 - 49}{121} = 2\ \frac{72}{121} = \frac{12}{10} \text{ nearly.}$$

Hence the power should be increased in the ratio of 6 to 5—that is to say, the engines at present capable of exerting a power of 500 horses should have been capable of exerting a power of 600 horses, and would, in this case, consume less fuel, as well as produce greater regularity. The following result also follows:—The vessel of less power burns 30 tons per day, performs the distance in fourteen days, consuming 420 tons of coal in fair weather. The vessel of less power burns 30 tons, performs the distance in twenty-two days, consuming 660 tons in foul weather. The vessel of greater power burns 36 tons, performs the distance in twelve and a half days, consuming 468 tons in fair weather. The vessel of greater power burns 36 tons, performs the distance in 17·5 days, consuming 630 tons in foul weather; being a consumption of 64 tons less fuel, and performing the journey in four and a half days less than the other. It is manifest, that the store of fuel carried in the vessel with less power, must, on all occasions, be equal to the greatest consumption, that is to say, at least 660 tons, whereas 630 tons will be sufficient for the vessel of greater power, and, as in all vessels for long voyages, coals carried are much more costly than the mere price of coals, or as the freight of the vessel is more costly than the fuel, coals carried are to be reckoned at least as expensive as coals burnt. Moreover, as the gain in time is 4½ out of 22, being 20 per cent., it is plain that the vessel may be calculated to do the distance oftener in a year, because, as the times of starting must be regulated not by the shorter, but by the longest period of a voyage, seventeen and a half days in the one case, stand in the place of twenty-two in the other. It appears, therefore, that, for long voyages especially, there are great advantages in point of economy, certainty, and speed to be obtained by the use of vessels of a higher power than usual; and that in a given case, the best proportion of power to tonnage may readily be determined from the rules already laid down. In regard to absolute or definite proportion, it may be stated, as the result of the best vessels, that the proportion of power to tonnage should not be greater than one horse power to two tons, nor less than one horse to three tons; the greater proportion holding in the smaller, and the less proportion of power in the greater vessel.

Mr. Fairbairn agreed, that the horse power should be increased, but that in bad weather the consumption of fuel was not so great as in fine weather.—Mr. Russell said, that practically in good weather the engines are worked expansively. There are two systems. The south engineers are afraid of using full powers; they use smaller proportions of power to tonnage, and slack the power in head winds. The north engineers always set head to wind in bad weather, and work full power; and in good weather work expansively. In steamers worked on the south system, the advantages would be as Mr. Fairbairn stated; in steamers worked on the north system, the advantages would be as he stated.—Mr. Fairbairn was of opinion, that three tons to one horse power were better than four to one.—Mr. Russell said, that it was safe to give more power than the rule gives; that on the introduction of longer and sharper vessels less power would be required.—Mr. Fairbairn observed, that the goverment post-office steamers, in the Mediterranean, were so bad, that the French vessels constantly pass them.

Mr. Smith made some observations "*On the Drainage of Railway Embankments and Slopes.*"—Mr. Vignoles observed, that had Mr. Smith had as much experience on railways and their construction as himself, he would have known that all he had recommended had been done on various occasions, whenever the expense could be justified.

Mr. Mallet "*On the Action of Air and Water on Iron.*"—Mr. Mallet stated, generally, the nature of the principal practical results obtained by him, with respect to the durability and modes of protecting cast iron, wrought iron, or steel, under various conditions, when exposed to the corroding or chemical action of air and water, whether fresh or salt. These researches have been made under the sanction of the Association, and are still in progress. Numerical results have already been obtained of the absolute and relative durabilities of about 100 different varieties or makes of cast iron and of wrought iron, in each of the following conditions as to water,—viz. In clear sea or ocean water; in foul sea water, as in the harbours of large cities; in clear river water; in foul river water; in sea water at high temperatures; in sea water at various depths; in sea water of variable saltness. The results in all these cases are given in voluminous tables, so arranged as to enable the engineer to predict with confidence the durability of a given scantling of iron of a given sort, under given circumstances. The conditions of corrosion of iron, in contact with copper, with zinc, and with tin, and with various atomic alloys of these, have been determined, and printed tables of the results distributed to the Section. Results are also given as to the relative protecting power of several paints or varnishes, to the surface of iron exposed as above. The specific gravities of all the irons experimented on, have been taken by a new method, and the increment of specific gravity due to increased depth (or head of metal) in castings determined, and also the decrement of specific gravity due to increased bulk or scantling of castings determined. These are necessary data to the foregoing investigation, and are in themselves of importance to the engineer, with reference to the ultimate cohesion of cast iron, which seems to be related, and probably is some function of the specific gravity in any given case. The experiments are now extended to wrought iron and steel; a final report is proposed, to consider the nature of the chemical changes induced on cast and wrought iron by the action of sea water, and to complete the numerical results now given, which have lately been in several instances submitted to control, or tested by the actual corrosion of castings recovered from the wrecks of the *Edgar* and *Royal George*, &c., and found strikingly to coincide.

Mr. Grimes described Dennett's Rockets for preserving lives from shipwreck, and read a letter from Capt. Denham, stating that the range of these rockets exceeded that of the mortar by 100 yards, the range of the rockets being about 350 yards, while that of the mortar was but about 250.

Dr. Wallace on Arches. The object of this paper was to exhibit a method for geometrically constructing a catenary. After explaining his method, Dr. Wallace stated that he was about to publish a set of tables for constructing the catenary, and also for suspension bridges.

Mr. Wallack exhibited and explained his smoke protector.—Mr. Hawkins exhibited and gave an account of Mr. J. R. Bakewell's instrument for measuring the angles of the dip of strata.—Mr. Rayner exhibited a machine for regulating the speed of machinery in cotton-mills, &c.—Mr. Smith, of Deanston, exhibited a model of a new canal lock, the advantages of which he stated to be, that the descent in each lock would not be more than twelve to eighteen inches—that the locks were opened by the passage of the vessels—that the locks shut of themselves—that the vessels did not require to stop—and that little or no water was lost. The lock gate is hinged at the bottom, the upper portion, which is round, floats at the level of the higher part of the water, and is pressed down by the bow of the vessel in passing, and when it has passed, rises to its former position.

Inquiry into the Strength of Iron, with respect to its application as a Substitute for Wood in Ship-building." By Mr. Fairbairn.

The number of vessels which of late years have been made entirely of iron, and the probability of the greatly extended use of this metal in ship-building, renders it desirable to attain additional knowledge as to its power to resist these strains to which it is subjected, in its application to the purposes above stated. Mr. Fairbairn's experiments have convinced him, that in proportion as the public become better acquainted with the valuable properties of this material, and its fitness for almost any purpose of naval architecture, they will be convinced that it is safer, and, perhaps, more durable than timber, and that confidence in it will be completely established. To meet the requirements for this purpose, the following series of experiments have been undertaken, and in a great measure completed. Part only, however, could at present be laid before the Section. 1st. A series of experiments on the strength of plates of iron, as regards a direct tensile strain, both in the direction of the fibre and across it. 2nd. On the strength of the joints in plates rivetted together, and on the best modes of riveting. 3rd. On the strength of the various forms of ribs or frames used in ship-building, whether wholly composed of iron, or of iron and wood. 4th. On the resistance of plates to compression and concussion, and on the power necessary to burst them. The experiments were superintended by Mr. Hodgkinson, to whom Mr. Fairbairn acknowledged himself indebted for many of the results.

On Strength of Iron Plates.—In these experiments all the plates were of uniform thickness. Their ends had plates rivetted to them on both sides, with holes bored through them perpendicular to the plate, in order that they might be connected by both, with shackles to tear them asunder in the middle, which was made narrower than the rest for that purpose. The results were as follow:—Mean breaking weight in tons per square inch, when drawn in the direction of the fibre.

		Tons.	
Yorkshire	plates	25·77	Mean 22·52 tons.
Do	do.	22·76	
Derbyshire	do.	21·68	
Shropshire	do.	22·83	
Staffordshire	do.	19·56	

Mean breaking weights in tons per square inch, when drawn across the fibre:—

Yorkshire	plates	27·49
Do.	do.	26·04
Derbyshire	do.	18·65
Shropshire	do.	22·00
Staffordshire	do.	21·01

The foregoing experiments show that there is little difference in the strength of iron plates, whether drawn in the direction of the fibre or across it. Mr. Fairbairn then gave the results of a long series of experiments on the strength of riveted plates. The same description of plates was here used, as in the previous experiments; the plates were however, made wider than the former, in order that they might contain (after the rivet-holes were punched out) the same area of cross section as the previous ones. Mean breaking weights in pounds, from four plates of equal section, rivetted by a single row of rivets:—

20127	Mean 18590 lb.
16107	
18982	
19147	

The mean breaking weights in pounds from four plates of equal sections to the last, but united with a double row of rivets:

23371	Mean 22258 lb.
20059	
22902	

Whence the strength of single to double riveting is as 18590 : 22258. But from a comparison of the results taken from the whole experiments, the strength derived from the double rivetted joints was to that of the single as 25030 : 18591, or as 1000 to 742. Comparing the strength of plates alone with that of double and single riveted joints, Mr. Fairbairn gave their relative values as under:—

For the strength of the plate	100
For that of double riveted joints	70
And for the single riveted joints	56

Hence the strength of plates to that of the joints, as the respective numbers, 100, 70, and 56. Mr. Fairbairn then gave a table containing the dimensions and distances of rivets for joining together different thicknesses of plates.

A discussion ensued as to the comparative strength and safety of iron boats. Mr. Fairbairn stated, that from the manner in which the sheathing is rivetted, the whole vessel becomes one mass; and though he did not come forward as the advocate of iron against wood, he would state that he considered iron as one-third stronger than wood, weight for weight.—Mr. Grantham knew iron boats that had lasted 28 years in fresh water.—Mr. Taylor built an iron boat for a canal in 1805, and it was now in good condition.—Mr. Mallett had found, from his experiments on the action of sea water upon iron, that the duration of a half-inch plate in sea water would be about 100 years.

Mr. Hodgkinson read a paper "*On the Strength of Pillars of Iron.*" This was an abstract of a paper by Mr. Hodgkinson, read at the Royal Society, of which we gave an abstract at the time.—(See Journal, No. 34, page 248.)

Mr. Fairbairn "*On raising Water from Low Lands.*" The commissioners for draining the Lake of Haarlem having applied to Mr. Fairbairn on the subject, he proposed a method where the water is raised by a large scoop, which rises on the descent of a weight, which weight is raised by steam power, on the Cornish principle. It is calculated to raise 17 tons at each stroke. Mr. Fairbairn exhibited a model in illustration.

Mr. Taylor mentioned, that he had that morning received a letter from Mr. Enys, stating that commissioners from the Dutch government had visited Cornwall, to ascertain the duty done by the Cornish engines. Several experiments had been made at their request, and the following was the result.

			Feet stroke.	Lifted one foot.
Wheal Vor, Borlase's engine..	80 in.	single	8·0	123,300,593lb.
Fowey Consols, Austin's	80	„	9·0	122,731,766
Wheal Darlington Engine ..	80	„	8·0	78,257,675
Charlestown United Mines ..	50	„	7·5	55,912,392
Ditto Stamping engine......	32	lifting 66 stamps		60,525,000
Wheal Vor, ditto	36 dble.	lifting 72 stamps		50,085,000

Mr. Glynn stated, that by a scoop wheel 25 feet diameter, and 80 horse power, used by him in Lincolnshire, 4¼ tons of water were raised in a second, the difference of level being about five feet.

Mr. Hawkins exhibited a Model of a Railway and Carriage, recently patented by Mr. Rangeley, and by him called *the Safety Rotation Railway;* which is an inversion of the ordinary construction, inasmuch as wheels are made to revolve on fixed bearings, placed in two parallel lines along the road; and the carriage, without wheels, is built upon a pair of running rails, carried along upon the peripheries of the train of wheels kept in revolution by steam-engines fixed at every mile or two of the road. It is intended to have the wheels three feet diameter, and three feet apart, which will give 1760 wheels on a mile. They are to be driven by a succession of endless bands, one band in every case passing around two pullies attached to every two contiguous wheels. The carriages are designed to hold forty passengers each, with their luggage; the whole, including the carriage, not to exceed five tons: the running rails always to bear on eight or ten wheels, so that no wheel shall have to support more than about ten or twelve hundred weight. The wheels, therefore, need not weigh more than half a hundred weight each, to be sufficiently strong for supporting the carriage. It is found by experiment, that three ounces suspended from the periphery of such a wheel, causes it to revolve. Any weight that sets a wheel in motion, will, if continued, cause the same to revolve with accelerated velocity, until the resistance of the atmosphere becomes equal to the accumulated force, after which, a steady speed will be kept up. It is inferred from observation, that the wheels driven with a continued force of three ounces each, would acquire a constant speed of about thirty miles an hour. It is also ascertained from experiment, that eight pounds would draw a ton weight on four three-feet wheels running on level rails, and thus that a force of forty pounds would draw the carriage. The following table is constructed from data, by which it is found that seventeen horse power of steam-engine is required to turn each mile of wheels, and two horse power to drive each carriage. The power to turn the wheels, is neither increased by additional carriages nor by acclivities: each carriage added, taking only two horse power more to carry it along upon a level; and an acclivity of 1 in 180 doubling, 1 in 90 quadrupling, and 1 in 45 octupling only the tractive force, without in any case requiring more than the seventeen horse power to turn the wheels.

Carriages Every 2 Minutes.	PASSENGERS. Every 2 Minutes	In 12 Hours	HORSE POWER. Per Mile in 2 Minutes. On a Level.	Up 1 in 180.	Up 1 in 90.	Up 1 in 45.
	40	14,400		21		
	80	28,800	21	25		49
	120	43,200	23	29	41	
	160	57,600			49	81
5	200	72,000			57	97

The Britannia.—This steamer has brought to Havre from London an iron steamer in 372 pieces. The vessel, which is destined for the Lake of Geneva, will be 135 feet long, and these materials are to be transported thither forth-

REVIEWS.

Penny Cyclopædia. Part 92. Article "PORTICO."

UNLESS the style adopted prohibits the introduction of such feature, a portico is now considered almost a *sine qua non* in a design; ample proof of which being the case was afforded by those for the Royal Exchange, the Assize Courts at Liverpool, &c.; and yet, whether in designs or executed buildings, we very rarely find any attempt at originality, or any fresh combinations in regard to plan. On the contrary, nearly all our porticoes consist merely of a single range of columns in front, and it is fortunate when that disposition of them is attended with the negative merit of there being no disagreeable drawback on the effect aimed at by them, resulting from a mean background to the external elevation. In fact, notwithstanding that so very much depends upon them, and almost endless variety may be obtained from them, *plan* and *background*—*i.e.* the interior elevation of the portico—have scarcely any study or attention at all bestowed upon them. We trust, however, that the very excellent article which has just appeared in the Penny Cyclopædia—a work which has already more than once obtained our notice and approbation for the architectural information it contains—will not be thrown away upon the profession, but spirit them up to endeavour to get out of their old routine course, and give us something more than six or eight columns, put beneath a pediment.

When we inform our readers that the article in the Cyclopædia extends to several pages, we hardly need observe that it is altogether original, for we know of no other work of the kind which contains much more than a mere definition of the term itself, while here in addition to the information brought together, there is a very great deal of able comment and criticism. Even were there nothing else to recommend it, this article would deserve to be noticed by us on account of the novel and ingenious terms invented by the writer to express clearly at once, of what kind a portico is, as regards its flanks, and its projection from the building to which it is attached. For this purpose he makes use of the terms *Monoprostyle*, *Diprostyle*, *Hyper-diprostyle*, *Triprostyle*, &c., the first indicating the simplest form of prostyle, namely, that which projects only one intercolumn before the building; the second, that which projects two intercolumns, and so on. By this most convenient innovation in architectural terminology,—and therefore likely to be generally adopted at once,—the plan of the portico of St. Martin's Church, would be clearly described by terming it Hexastyle Diprostyle, that is, having six columns, or five intercolumns in front and two intercolumns at its flanks, consequently one column there besides that at the angle. A *Triprostyle* has of course three open intercolumns at its sides; but the meaning of *Hyper-diprostyle* requires some explanation,—after which it becomes obvious enough, this term being coined by the writer to express that besides having two open intercolumns, the portico is advanced from the building by an additional space, whether equal to a third intercolumn or not: thus the portico of the National Gallery is described as a Corinthian Octastyle, *Hyper-diprostyle*, and with regard to its interior as having a distyle in antis within it,—that is, a recess of three intercolumns, produced by two columns between antæ.

The article is illustrated with a great many plans, showing various arrangements, and is further accompanied with a table of some of the more remarkable examples, which we shall here give, referring our readers to the Cyclopædia itself for the rest of the article, not doubting that they will procure the number which contains it.

TABLE OF PORTICOES.

Class.	Order.	Building.	Architect.	Remarks.
Dodecastyle	Corinth.	Chamber of Deputies, Paris	Poyet	Monoprostyle sculptured pediment
Decastyle		University College, London	Wilkins	Hyper-diprostyle, recessed. Height of columns 30 feet.
Octastyle		Pantheon, Rome		Hyper-triprostyle. Polystyle and recessed.
		National Gallery, London	Wilkins	Hyper-diprostyle, with distyle in antis, recess within.
		Fitzwilliam Museum, Cambridge	Basevi	Monoprostyle, recessed, and with order continued laterally, forming three intercolumns on each side
		Victoria Rooms, Bristol	Dyer	Unequal diprostyle, recessed five intercolumns
		Exchange, Glasgow	Hamilton	Diprostyle, with two inner columns corresponding with second and seventh of the octastyle
		Buckingham Palace	Nash	Columns fluted, their height 26 feet
Octastyle-Peripteral		Birmingham Town-hall	Hansom and Welsh	Columns 36 feet high. Side elevations of twelve intercolumns on flanks.
		La Madeleine, Paris	Huvé	See PARIS.
		Girard College, Philadelphia	Walter	Columns 55 feet high, marble.
	Doric	The Walhalla, Bavaria	Klenze	
Octastyle	Ionic	Glyptotheca, Munich	Klenze	Monoprostyle, polystyle, recessed, tetrastyle in antis.
	..	Great Theatre, Petersburg	Thomond	Monoprostyle.
	Doric	Church at Possagno	Canova	Diprostyle, polystyle, double octastyle
		Manège, Petersburg	Quarenghi	Monoprostyle, polystyle, recessed.
		Royal Institution, Edinburgh		
Hexastyle	Corinth.	St Martin's, Charing-cross	Gibbs	Diprostyle, height of columns 34 feet.
		St. George's, Bloomsbury	Hawksmore	Diprostyle, five arched doors, and five arched windows above them.
		St. George's, Hanover Sq.	J. James	Monoprostyle.
		Law Courts, Dublin	Cooley and Gandon	Monoprostyle.
		Kasan Church, Petersburg	Voronikhin	Diprostyle, polystyle, a triple hexastyle.
		Pantheon, Paris	Soufflot	Reliefs within portico, height of columns 62 feet.
		Madre di Iddio, Turin	Buonsignore	A diprostyle, attached to a rotunda. Two inner columns behind the penultimate ones in front.
		Custom-house, New York	W Ross	Monoprostyle. White marble, columns 32 feet high.
		St. Nicholas's Potsdam	Schinkel	Hyper-monoprostyle.
	Ionic	Bethlem Hospital, London	Lewis	Monoprostyle, height of columns 36 feet.
		Post-office, London	Smirke	Diprostyle, recessed, columns 37 feet high.
		Theatre, Berlin	Schinkel	Monoprostyle, flight of steps in front.
		East India House, London	Jupp	Pseudo-prostyle; height of columns 30 feet.
		St. Pancras' Church, London	Messrs. Inwood	Monoprostyle; florid Ionic; columns 36 feet high.
		Royal Institution, Manchester	C. Barry	Monoprostyle. Order continued laterally, forming loggias of three intercolumns on each side of prostyle.
		Post-Office, Dublin	F. Johnston	Monoprostyle, columns 36 feet high, fluted.
			Hansen	Monoprostyle; deep recess in centre with steps.
	Doric	Colosseum, London	D. Burton	A monoprostyle attached to a polygon.
	..	Hunterian Museum, Glasgow	......	Monoprostyle, recessed, with a distyle in antis.
	..	County Hall, Chester	T. Harrison	Monoprostyle, polystyle, recessed. A double hexastyle.
	..	Wacht-Gebaude, Berlin		Monoprostyle, recessed as a tetrastyle in antis.
Pseudo-hexastyle		Front of Roman Catholic Chapel, Finsbury Circus		Four pilasters and two columns beneath a pediment, or five intercolumns.

Papers on Iron and Steel, Practical and Experimental. By DAVID MUSHET. London: Weale, 1840.

SECOND NOTICE.

Iron possesses among metallic products the same pre-eminence which cotton has over those of vegetable origin, and has for many centuries been one of the great staples of our foreign trade, and a main supporter of our internal industry; to the progress of this manufacture in our own country we shall subsequently have occasion to refer, we shall now therefore call attention to its origin elsewhere. Mr. Mushet in his fourteenth paper combats the traditional account of the discovery of iron in Greece by the accidental burning of a forest, and gives a probable theory so well confirmed by experience here as to carry with it a high degree of authority. I have seen, says he, a mass of perfectly malleable iron produced by roasting a species of ironstone, united with a considerable quantity of bituminous matter. After a high temperature had been excited in the interior of the pile plates of malleable iron of a tough and flexible nature were found, and under circumstances where there was no fuel but that furnished by the ore itself. Mr. Mushet thence argues the possibility of the properties of the metal having been discovered during the process of making charcoal by a mass of ore accidentally dropping into the burning pile. Iron, it is most probable, was for a long time after its discovery applied solely to agricultural purposes, for the want of a regular method of converting it into steel long gave a preference to hardened copper and its alloys as the material for edged tools and instruments of war. So little indeed was the art of making steel advanced, that a present of 40 lbs. of steel from Porus to Alexander is quoted by biographers as a most acceptable and valuable gift.* Even in India itself where this branch of art is now carried on upon a very extensive scale, the progress seems to have been very slow, for the value of that gift of Porus would now be the produce of one man's labour in 240 days. It is to India however, that according to the best authorities we are to look for the origin of steel, and from which other countries were supplied; even the obelisks of Egypt being supposed to have been worked with Indian tools. Among ourselves the production of iron claims a very early date, for there is every probability of the Cornish mines having been worked at least 2300 years ago by the Phenicians, while we know by the testimony of Cæsar† that this branch of mining was still pursued by the nations inhabiting Britain. The current money was of brass or iron, valued according to weight, although Cæsar observes that the produce of this latter metal, which was worked in the maritime districts was small. As however the tin trade had long been a staple, and copper and brass were imported, it may be reasonably doubted whether among a mining population, the workings were, although rude, carried on upon a greater scale of magnitude than is implied from the terms used by the Romans. During the subsequent occupation by the Romans, remains now existing fully attest that the workings were kept up by them, and indeed during the whole period of history there seems to have been no intermission in the prosecution of this branch of the national wealth and strength. The Danes are particularly noted in this pursuit, and large heaps of scoria, named after them, are to this day to be met with in many parts of England, with so great an accumulation of soil upon them as to bear trees of large size. At the time of the Norman accession we find the king demanding of the inhabitants of Gloster 36 icres of iron, for making nails for his fleet, every icre to consist of 10 bars or rods of iron; which iron was very probably made in the neighbourhood in the Forest of Dean. The kings of England held in this forest iron works, consisting of three blast furnaces and two forges, which are supposed to have been given up by Charles 1st, somewhere about the year 1637. Cromwell and other princes are also said to have embarked capital in such pursuits, and indeed the iron trade seems always to have been the object of the highest solicitude.

One of the first events which led to an extension of the iron trade, particularly as regards castings, was the invention of cannon, the precise date of which is not however known. Cast iron is said by M. Verlit to have been known in Holland in the 13th century, and staves to have been cast from it at Elass in 1400, but how produced is not known. Cannon are mentioned in a record of the accounts of the Chamber of Paris in 1338, and were used by the English at Cressy in 1346, and by the Venetians in 1366 and 7, but we are by no means to conclude that such cannon were cast, as for two hundred years hooped cannon were made, formed of staves of wrought iron, bound together with strong hoops of the same metal. It was not until 1547 that the first iron guns were cast in London by a person named Owen. The precise date of the origin of the blast furnace is far from being ascertained. Mr. Mushet who has investigated the subject with his usual research, seems to be of opinion that it cannot be beyond the beginning of the seventeenth century. It is then that we perceive a fresh epoch in the progress of the manufacture, as a greater power of blast was required, the old situations would be abandoned, and the iron trade pass from the township in the neighbourhood of the mines to the banks of the adjacent streams; this is particularly evident from examining the sites of the oldest workings. The introduction, or invention of the blast furnace here, for we seem to have some claim to its first use, was productive of a great extension of the trade; a great exportation of iron artillery to the continent was the result, and without giving implicit belief to the statements of Dudley, in his Metallum Martis, we are still bound to believe that the trade was great. According to Dudley's computation in 1615, there were then no less than 300 blast furnaces for smelting iron ore with charcoal, and 500 forges and iron mills. The total quantity of iron produced from the works is said to have been 180,000 tons per year, an enormous amount considered in relation to the then population of the country, although not impossible so far as the question of fuel is concerned. Supposing Dudley's statement of the number of furnaces to be accurate, although some question may be raised upon that point, a deduction is still to be made for furnaces out of blast and building, for which, from modern experience we might easily assume the deduction of a third, leaving 200 as the actual number in work. A less number of weeks (perhaps 35), and a lower average (say 12), should also be taken, and the estimated produce would then not exceed 80,000 tons, a quantity by no means incredible. It may be mentioned here by the way that the extensive exportation of artillery is not only in favour of the origin of blast furnaces in this country, but also of our possessing a very large share of this trade, which might well give an impulse to it in this country.

We have now to contemplate the history of another great improvement, the use of pit coal, for which we find several patents granted by James I. In 1612 a patent was granted to Simeon Sturtevant, Esq. (seemingly a Dutch name) for 31 years for making iron with pitcoal, in return for which patent Sturtevant was bound to publish his discoveries, which appeared in a quarto form under the name of "Metallica." In the next year Sturtevant, having tried his plan upon a large scale and failed, was obliged to give up his monopoly. John Ravenson, Esq., was the next in the field, and was also enjoined by his patent to publish his discoveries, which he did under the title of his "Metallica." Several other candidates also failed, when, in 1619, a new competitor came into the field, who was destined to excite more attention. Dudley's father possessed iron works at Pinsent, in Worcestershire, and it was there that Dudley perfected the patent which he obtained in 1619. He declared that although he made only at the rate of three tons of pig iron weekly, that he made it with profit. His success was such as to excite the alarm of the charcoal iron manufacturers, who formed a powerful opposition, and obtained a limitation of his patent from 31 to 14 years, new adventurers also sprang up to encroach upon his rights, until at last their rivalship, and his attachment to the cause of Charles 1st, prevented his improvements from being followed up. In the meanwhile the deficiency of wood had begun to be felt, and Dudley had fully proved the efficacy of his plan for the manufacture of pig and bar iron, and for various castings, all of which he sold much lower than the charcoal-manufacturers. In the article of castings alone, Mr. Mushet says, he must have had greatly the start of the charcoal foundries, as the quality of carbonated coke pig iron is far superior to that of the charcoal iron of this country for the general purposes of casting. Such success greatly provoked the hostility of his rivals, particularly of those who still possessed a good supply of fuel, who at last in the true spirit of combination led on an attack upon his devoted works, and led to the evil results to which we have alluded. His improved bellows, forge, &c. all fell a prey to the lawless banditti. While he was thus openly plundered, his rivals were not less active in endeavouring to undermine him, or at least profit by his success by evasions of his patent. Among these attempts that of Captain Buck, Major Wildman and others is a singular instance of failure. Attacked on all sides Dudley was also foiled in 1663, in his last attempt to obtain a patent from Charles the Second, and deserted by all, he was compelled to give up the pursuit.—Dudley was the author among other works of the "Metallum Martis," in which we possess many curious details of the early state of the trade. We may here pause and view the present state of the charcoal iron manufacture, which from 310 furnaces has dwindled down to insignificance, so as to be almost extinct, the whole annual quantity manufactured not exceeding 1000 tons. In Lancashire, two or three furnaces are occasionally in blast, and one in Argyleshire. The purposes to which iron made from this fuel is now applied are limited indeed. In Lancashire a small quantity of steel-iron for the Sheffield market has of late years been made from it, but the principal consumption is for casting [illegible]

* Quintus Curtius, B. 9. ch. 23. Ferri candidi talenta centum.

† De Bello Gallico, L. 5, c. 12.

stirrup irons, &c. These articles, after having been cast, undergo a process of deoxidation, which gives them a surprising degree of tenacity, with great flexibility and a capacity of polish resembling steel; these castings, not intended to receive a polish, present surfaces capable of receiving and retaining tin for a considerable length of time.

To return to the date where we left off, we may observe that the improvements which had been made had increased the power of the furnaces, from which as well probably as from their concentration a diminution had taken place in their number. In a prospectus drawn up about the year 1720, near the time of the South Sea Bubble, we find the number of furnaces rated at only 59, but as this list is manifestly imperfect, we are perhaps bound to consider the number as larger. Sussex, Kent, and Hampshire were then the seat of 15 furnaces, now of not one. Resuming the history of pitcoal iron we find that after the time of Dudley, nothing of importance was done until 1740, when a new auxiliary, the steam engine, had come into the field. The application of this machine gave the manufacturer greater liberty in selecting the site of his works, and enabled him to erect larger furnaces with a proportionate quantity of blast. From this date the use of pitcoal every year became more prevalent, and has ended by superseding charcoal in this country. In aid of this two other circumstances operated with advantage, the introduction of Mr. Watt's double blast engine, and the invention of puddling and rolling bar iron by Mr. Cort.

In our own days improvements not less important have been effected, and since the commencement of the literary career of the author, whose work is now before us, the quantity of pig iron necessary to produce a ton of bar iron has been reduced from 40 cwt. to 26 or 27 cwt., with almost as great an economy of fuel. This has principally been accomplished by means of the hot blast, the use of which however can be only considered as recently established, so strong was the prejudice against its application. One great property it possesses is that it diminishes the quantity of vitreous matter formerly required in the furnaces, so as to diminish the consumption of both fuel and limestone. An equalization of the blast is another result, so as to diminish the effect of the atmospheric influence, which it is well known interferes with the operations of the furnace. In this, as in other countries, a larger produce of cast iron is obtained in the winter months than during the summer or autumn, while the quality of the metal is improved by being much more carbonated and less fuel is consumed. During the months of June, July and August, more especially in hot seasons, the quality of the iron in this country will be depreciated 30 per cent., and the quantity very considerably reduced, and in many parts of Sweden, says Mr. Mushet, when the summer heats are intense, the manufacturer is obliged to blow out or stop his furnace for two or three months; not only is he unable to make carbonated metal, but is frequently incapable of keeping the furnace in such trim as to make a produce of any quality whatever.

An improvement scarcely inferior in importance, although only local was the discovery by the author in 1801, of the Mushetstone or Black Band ironstone, a new class of carboniferous ironstone, principally found near the river Calder, near Glasgow, but also in South Staffordshire, North Wales, and North Staffordshire, in which latter district it is called Red Mine. Although used by Mr. Mushet in the Calder iron works, so strong was the prejudice against it that it was not until 1825 that its application was at all extensive. It is now used in about 50 furnaces in Scotland, and the quantity of iron produced is above 100,000 tons; on one estate alone £12,000 is received as royalty in consequence of this discovery. A powerful auxiliary in the hands of the Scotch masters has been the use of raw pit coal, and coking under dust, which have been found to be particularly suited to the Scotch coal and iron. A dawning discovery and one which promises to be not less important than that of the Mushetstone, is Mr. Crane's process for smelting iron with anthracite, thus making available a large supply of mineral wealth, and extending our national resources.

A Practical Inquiry into the Laws of Excavation and Embankment upon Railways, being an attempt to develop the natural causes which affect the progress of such works, &c. By a a Resident Assistant Engineer. London: Saunders and Otley, 1840.

It may be laid down as a general axiom that in every inquiry of this nature, the degree of dependance which shall be placed upon the laws established, should be proportionate to the extent and generality of the experiments on which such laws are founded.

If we take as our groundwork the gross performances of a long series of months during which the attendant circumstances as to weather, [illegible] of the earth, as it may be wet or dry, adhesive, loose, or crumbling, [illegible] the other circumstances by which earth-works are affected, we shall be able to deduce from these in connection with detailed experiments upon the requisite particulars of getting, filling, teaming, and times of travelling, a tolerably perfect set of expressions by which calculations may be made with reference to earth works in general.

It must be borne in mind, however, that all results derived from such expressions, however accurately determined, and however comprehensive the data from which they have been derived, are still liable to be affected by circumstances which no human foresight can predict. All that can ever be with safety relied upon is, that supposing all attendant circumstances to be identical as to effects with those which had place during the period of former observations, then that the calculations applied to other works varying in form and magnitude, shall give results agreeing with such former observations.

But if we attempt without reference to the gross performance during some long period, to derive from the observation of a few days, fixed laws for the actual time of executing large works, it is obvious how impossible it must be to derive correct results in any such way. The days during which the observations have been made, may have been remarkably fine or remarkably unfavourable, or in some intermediate stage between these. But whatever this stage may have been, there is no alternative but to adopt them as our standard for the whole year, and thus it will be seen on what an unstable foundation such a structure must be raised.

We do not mean to say that any experimentalist would so far stultify himself as to proceed blindly on the isolated experiments of certain days on which the performances would notoriously be either much less or much more than on the average of the year, but we can readily imagine that the imputation of improper selection can scarcely fail to apply more or less to the experiments of any 10 or 12 single days at any period of the year. Let us suppose on the one hand one of the dull gloomy days of our winter months, the ground slowly parting with the frost which had hardened it for some weeks before—the falls of earth possessing more than usual tenacity, the workmens' tools clogged with the soft retentive clay adhering to every thing like bird lime; the rails clammy and dirty from the same cause, the wagons when teamed retaining a third of their contents plastered to the sides and bottom, and so requiring double the time for teaming, and then let us with this contrast a fine dry day of spring or autumn, the rails almost free from dirt, the shovels all clean and bright, and parting instantly with the contents filled into the wagons. These latter again when tipped immediately discharging their contents, and leaving none to be shovelled out by the teamers. And let us ask any man, practical or not practical, on which day the performance will be greatest. We shall not hesitate to say that the performance on the one day shall be 50 per cent. more than on the other, and shall be independent of the number of hands employed, because assuming that on the favourable day each department of the labour is occupied by the proper proportion of men and horses, then on the unfavourable day an increased number will rather serve to impede than to hasten, as they will be in each others way, and the hands will at intervals have to wait for their turn to exert themselves, it being impossible that more than a certain number at a time can be fully employed.

We repeat we have no intention of charging the experiments before us, or any other of the same kind with such glaring absurdity as would attach to them, did they exhibit the extraordinary results of one or other of the extremes we have pointed out as a foundation for estimating the work of the year, but we contend the chances are, that as isolated experiments they bear more or less to one or other of the extremes. It is barely possible that the days selected shall represent a fair average of what may be done throughout the year.

It is for such reasons that we would hesitate before adopting as the basis of important calculations, the results of a few days observation.

We would much rather rely on well authenticated records of the performance during many months, under different systems of working, and we would suggest to the author of the present treatise, and to all others who may in future undertake experimental inquiries of this nature, that the really practical and experienced, whether engineers or contractors, will invariably. as their test upon the accuracy of any particular theory, however derived, proceed at once to compare the results which such a theory will give them with their own actual knowledge of what has been done on the great scale in other works. They will therefore pronounce the theory correct or otherwise, according as it coincides or disagrees with their own experience. We are thus over and over again impressed with the importance of founding all theories upon the actual performance of as long a period as possible.

Let it not be understood that we are here objecting to experiments in detail. These are exceedingly useful, because placing as they do before our eyes the precise amount of time occupied in all the various [illegible] cutting till it is finally placed in the embankment, we are better able justly to apportion the quantity of labour necessary in each several department, and so to economize both time and money.

Our author professes to have selected the experiments he has given from a much more extensive series, and this may possibly be held as an answer to our objections, as to the limited space over which the experiments extend, but it must be understood we are not objecting to the insufficiency of these experiments, for the purpose of showing the distinct periods of time occupied in the several processes of filling, tipping, and travelling; the real meagreness of the experiments, we conceive, arises from the absence of all information as to the gross performance of some long periods. It is obvious that with such information, even should the results not agree with those which might be derived from calculation by the author's formulæ, these latter might still be of service, as expressing the ratio of the times occupied by the various details of earthwork operations, and this, we apprehend, is almost the extent of what can be expected from the experiments we are considering.

Thus should we find that the calculations on being applied to any particular work already executed, shall afford a less result in point of performance than we actually know to have been accomplished, we may still perhaps rely upon the numercial relation to each other of the several times determined in the experiments, which form the basis of such calculations. We may conclude that the separate times assumed for filling, teaming and travelling are all too great, but that they may all safely be reduced in a certain ratio: and when so reduced we may be satisfied with the conclusions they establish. Thus for purposes of comparison as to the amounts of labour which can most advantageously be employed in the several departments of earthworks, we hold the experiments in this book to be extremely useful, and we think with the restriction we have laid down against applying them to establish gross results, that they may be safely depended upon.

We will now briefly describe the mode of investigation pursued in this work.

From the observations of sixteen days the author proceeds to establish first the rate of speed at which the wagons travel, and then the time occupied in tipping each wagon, or each set of wagons, supposing a sufficient number of men at the teaming place to prevent unnecessary delay. His method of deriving the rate of speed is neat and ingenious, and liable to less objection than actual observation on the time of passing between fixed points. For instance, the time occupied in "filling, removing, and tipping the wagons," as the average of several experiments, on a lead of half a mile, was 55 minutes. Also the time occupied in filling, removing, and tipping the wagons on a lead of three-quarters of a mile, amounted to 69·47 minutes. Hence we have $69·47 - 55 = 14·47$ minutes for the difference between the time required for filling, removing, tipping and bringing back a set of wagons upon a lead of three-quarters of a mile long; and the time required for filling, removing, tipping and bringing back a set of wagons upon a lead of half a mile long. This difference, namely, 14·47 minutes is evidently the time which elapsed while the horses were drawing the loaded and empty wagons backwards and forwards over a quarter of a mile, or in fact the difference in the lengths of the leads.

"This shows that the average speed of transit rates at 2·40 miles per hour."

We regret to be under the necessity of pointing out that the author has here made an error in calculation, as may at once be verified by ascertaining the rate of speed corresponding to half a mile in 14·47 minutes. This rate will be found equal to 2·07, instead of 2·40 miles per hour; a material difference, and one which must affect any subsequent calculations founded upon it. We believe that the rate made use of by the author, namely, 2·40, is more correct in practice than the other, but this tends rather to weaken our faith in the experiments, since they undoubtedly, by the author's own showing, establish 2·07 miles per hour as the rate of horses' speed in transporting earth. To proceed, the time of tipping is then found $= 7·06$ minutes, and that of filling $= 19$ minutes, both these being derived, independently of the rate of speed, and so not affected by the error we have pointed out above.

From the data thus established, our author derives in a simple manner, the necessary expressions for finding the number of wagon loads which may be removed from cutting to embankment in a given time, with a given number of wagons, both for constant and varying loads.

The next section is devoted to the investigation of the causes which limit the rate of progress in forming an embankment. The author shows that this rate of progress is limited by the number of teaming, or as he terms them shunt roads, which can be fixed at the end of the embankment, and this number will of course depend upon the height, top breadth, and rate of slopes of the embankment, as affording a greater or less breadth to team over. The breadth occupied by each road, he assumes at 8 feet, so that the whole breadth available for teaming over being divided by 8, will give the number of roads which can be laid down.

It will now be necessary to notice the author's hypothesis as to the available breadth of the teaming or battery head. He assumes that most soils will stand at a slope of 1½ to 1, when first tipped, and as most embankments are to be finally dressed off to flatter slopes than this, the difference between the base for a slope of 1½ to 1, and that for the slope to which the embankment is to be finally dressed off will be so much additional breadth, which being added to the top breadth will give the whole available breadth for teaming. Thus for an embankment 40 feet high, slopes 2 to 1, and top breadth 30 feet, we shall have $\overline{40\times2\times2}+30-\overline{40\times1\frac{1}{2}\times2}=190-120=70$ feet, the available breadth for teaming over in this case.

This brief analysis contains, we believe, the elements of the author's theory, as to the limits of progress in an embankment, for taking 7·07 minutes as the time of tipping a set of wagons, it is evident that 84·8 can be tipped from each shunt road in a day of 10 hours.

The number of wagons that can be tipped per day from each shunt road, being multiplied by the number of these roads, gives the total number of wagon loads that can be tipped per day from all the roads, and this number being multiplied again by 250, the working days in a year, gives the whole performance in wagon loads per annum.

The quantity in cube yards depends of course on the capacity of the wagons, which varies from two to three cube yards, according as they are heaped or not, and according to their build.

Our opinion of this part of the author's work is principally influenced by comparing the gross results which his calculations establish as to the rate of progress, with what we know to have been the actual performance in cases where every effort was made to get through as large a quantity of work as possible. Taking the case of an embankment 50 feet high, slopes 2 to 1, and top breadth 30 feet, it would appear by the formulæ that we have been considering, that 848 wagon loads, or say (at the most moderate allowance for each wagon) 1696 cube yards per day of 10 hours, can be tipped at each end of the embankment. We think our author would be somewhat puzzled to point out an instance where even two-thirds of this amount has ever been performed, under the circumstances we have supposed, even for a single day, much less during any long continued period.

There is some difficulty in comparing the formulæ in detail with actual performance, for the want of knowing the breadth of tip in the latter cases. There is however one well authenticated example which may be found in the evidence of Mr. Provis, on the London and Brighton Railways.

We allude to his description of the great Skelmere embankment on the Birmingham and Liverpool Canal, where he states, that over a breadth of 60 feet, 105,000 yards were teamed in 16 weeks during fine summer weather, being at the rate of 1094 cube yards per day.

"During one month," however, says Mr. Provis, "we worked double gangs, beginning at three in the morning, and ending at ten at night." So that this quantity reduced to days of ten hours in length, becomes 105,000 in 120 days, equal to 875 yards per day. It must be remembered that Mr. Provis was here certainly not *understating* the performance on this work. It was his interest to show the greatest possible quantity which had ever before been accomplished, and the fact he relates was considered at the time, as indeed it is entitled to be considered now, a wonderful and almost unexampled performance, exhibiting no small share of contrivance and energy on the part of those directing the operations.

We shall only further remark that up to April 1837, no instance could be found where even 200,000 yards had been teamed into embankment from one face in a year; whereas our author's formulæ for an embankment of the dimensions last described, would lead us to calculate taking 250 working days in a year, as a performance of 424,000 yards per annum, and this too without nightwork, but simply during 250 days of 10 hours each.

The difference between actual experience and the results of our author's experiments arises here, we conceive, principally from the use of the constant 7·07 minutes as the time of tipping. This time may be perfectly correct as applicable to small embankments, and a few sets of wagons where there is no danger that either men, horses, or wagons will ever be in each others way, but we conceive it is quite inapplicable to large works, where interruptions to the regularity of proceeding would inevitably be very frequent, if the wagons were worked with the proper complement of labour to ensure the condition that no instant of time shall be lost at the teaming place. Thus it will ever be found that the theory here laid down furnishes results as to gross performance, which must not be expected in practice.

The second part of the work commences with an inquiry into the effects of the lead, principally as determining the number of wagons to be employed for different lengths of lead. Without accompanying the author through his investigation of this subject, it may be sufficient to say that while his theoretical deductions from certain assumed data cannot be objected to, yet these deductions are certainly at variance with what any practical man would think of adopting. For instance, he ascertains by means of this investigation, that for working a 20 feet embankment at one end only, and for a lead of 150 chains, there should be employed no fewer than 109 horses and 285 wagons, a proposal sufficiently monstrous to startle any one at all acquainted with the nature of earthworks.

The next section is devoted to an examination "of the amount of friction incident upon contractor's rails." The author here establishes that the gross load for a horse on contractors' rails may vary (on a level?) from 5·28 to 7·17 tons, so that knowing the weight of the wagons employed, and deducting this from the gross load mentioned above, we may readily ascertain the number of wagons to be assigned to each horse, provided the quantity of stuff which each wagon is to hold be known, or *vice versa*, the quantity of stuff which each wagon is to carry, according as 1, 2, or 3 wagons are to be drawn by each horse.

The following extract from this section exhibits the author's results derived from an examination of the friction.

"Let P represent the power of a horse, F the friction per ton, upon the load which he draws, and W the weight of a loaded wagon in tons; then it follows, that

$$\frac{P}{F \times W} = X$$

is the load proper for each horse, expressed in wagons; and this value of X has been given in the following table:—

TABLE, GIVING THE LOAD PROPER FOR A SINGE HORSE, EXPRESSED IN WAGONS, ACCORDING TO THE STATE OF THE WEATHER.

Value of F in lb.	Value of W in tons.	Value of P in lb.	Value of $\frac{P}{F \times W}$	Value of X.	State of the weather.	Remarks.
25·45	3·43	188·27	$\frac{188{\cdot}27}{25{\cdot}45 \times 3{\cdot}43}$	2·09	Fine.	Rails in good order.
31·22	3·43	188·27	$\frac{188{\cdot}27}{31{\cdot}22 \times 3{\cdot}43}$	1·75	Fine.	Road wet, and rails greasy.
26·86	3·43	188·27	$\frac{188{\cdot}27}{26{\cdot}06 \times 3{\cdot}43}$	2·04	Fine.	Rails and road in tolerable order.
35·54	3·43	188·27	$\frac{188{\cdot}27}{35{\cdot}54 \times 3{\cdot}43}$	1·54	Wet.	Road and rails in very bad order.

We observe that in several pages of this section the erroneous velocity of 2·40 miles per hour is made use of.

The eighth section contains a summary of those preceding, but as we have already considered these so minutely, it may be unnecessary to remark particularly on the summary.

The remainder of the work is occupied by an investigation into the barrowing system, our notice of which we must defer till next month, and in the mean time we may safely recommend the work to the younger branches of the profession, as exhibiting a very neat, clear, and simple application of algebraical calculation to subjects of practical inquiry.

For the reasons already so fully stated, we cannot advise dependance on the gross results to be derived from the author's mode of calculation, but whenever the student shall either from his own, or the experience of others, have acquired sufficient *data* to found his calculations upon, then the method of handling the subject generally, and particularly of adapting calculations to the practical facts on which they are established, will be found exceedingly useful.

A great deal of useful information may also be gleaned from the observations detailed in the work, and the young engineer in particular, can scarcely fail to have his knowledge of the subject improved by a perusal.

Report of a Proposed Line of Railway from Plymouth to Exeter, over the Forest of Dartmoor. By JAMES M. RENDEL, C.E. Plymouth: Stevens, 1840.

This is a well drawn up report, but we can do no more than call attention to the mode proposed of working the inclines, respecting which we may also mention that a similar plan is described in the First Volume of the Journal.

"From the point of divergence of the Tavistock branch, the main line ascends to Dartmoor; the prevailing gradient being 1 in 38, and the plane 5 miles 860 yards. This part would be worked as one continuous plane, by two water wheels, each equal to 160 horse power, constructed at the head of the plane, and supplied with water as hereafter to be described. The rope to be used for drawing the trains up this plane would be what is technically called an end rope, of the whole length of the plane; being very little longer than the rope similarly used on the London and Blackwall Railway, upon which there is an enormous passenger traffic."

"To insure a supply of water for working the water-wheels before described, by which the trains are to be drawn up the two great inclined planes, at a velocity of not less than from 15 to 20 miles an hour, I propose to throw dams across the gorges of the following valleys on Dartmoor, viz.—across the Blackabrook valley east of the prisons of war, the Cowsick valley above Two Bridges, and the East Dart valley, about three miles north of Post Bridge. These reservoirs would have an area of 255 acres, with an average depth of 20 feet, and contain a sufficient quantity of water, during a continued drought, to pass eight trains per day up the planes, for three months; their height above the wheels is from 50 to 300 feet. The great depth of these reservoirs will cause their supply of water to be independent of the severest known frost; whilst from their height above the Railway, the leats by which the water is conveyed to the wheels, will have so quick a descent as to prevent all chance of the passage of the water being interrupted by either frost or snow. The wheels will work under ground, or rather, in chambers under the Railway, and would not therefore be affected by weather."

The Process of Blasting by Galvanism, addressed to the Highland and Agricultural Association of Scotland. By MARTIN J. ROBERTS, F.R.S.E.

In mentioning that Mr. Roberts has been as successful in Scotland with blasting by Galvanism, as Col. Pasley has been in England, we say enough for the merits of Mr. Roberts. We may farther observe that this small pamphlet contains in addition to a good description of the process, several illustrative plates.

Scott's Practical Cotton Spinner and Manufacturer. By ROBERT SCOTT and WILLIAM SCOTT. Preston: Livesey, 1840.

We are glad to perceive that a useful class of works by practical men are springing up in the manufacturing districts, and likely to prove of great benefit. The book now before us is a collection of calculations applied to the several parts of cotton spinning machinery, adapted equally to the use of the engineer and the manufacturer. It seems indeed to be a most useful work.

A Glossary of Civil Engineering. By S. C. BREES, C. E., &c. London: Tilt, and Weale, 1840.

Mr. Brees seems to have been so successful with his previous works, and rendered so confident by his good reception by the public, that after a very short interval he is again before us. The present work is one of less pretensions than those usual emanating from his pen, being a glossary of the terms used in civil engineering, adapted for popular use, and that of the younger members of the profession, and very useful as a handbook of reference. It is copiously illustrated with woodcuts, some of them of considerable artistic pretension. We should have wished that Mr. Brees had given a little more room for mining terms, of which a manual is much wanted.

The Martyr's Memorial, Oxford. By S. S. SCOTT, and W. B. MOFFATT Architects.

This fine monument is an elevated cross in the pointed style, of majestic proportions, having in the second story statues of the three bishops. The cross is raised upon a series of steps, and we are glad to observe without an iron railing round it. The irregular pinnacles of the church in the back ground are made by the cross to look rather awkward, and should be made more symmetrical—we should suggest, by the gentlemen who have so well fulfilled their previous task.

Ricauti's Rustic Architecture, No. 5. London: Grattan and Gilbert, 1840.

Mr. Ricauti goes on with success in his undertaking, he has shown completely how much beauty may be combined with economy by the simplest means. Even the woodman's axe is an efficient instrument in Mr. Ricauti's hands for giving a picturesque appearance to unbarked trees and small branches. It appears to us that in several of the plans Mr. Ricauti might have greatly promoted the convenience of the arrangements by a few slight alterations.

The Dominican Convent and Chapel at Atherstone, Warwickshire. By JOSEPH HANSOM, Architect.

These buildings were finished in August 1839, and consist of a pile of mixed character in the pointed style. The turret or spire attached to the chapel is a new arrangement of the details of the pointed style, but it appears to us to be rather out of character with the remaining portions.

A Brief Survey of Physical and Fossil Geology. By Frederick John Francis. London: Hatchard, 1839.

This small work is a republication of two lectures delivered at Literary Institutions, and therefore well adapted for popular circulation. The object of such a performance almost places it out of the range of criticism, particularly, whereas in this instance, the work seems carefully compiled.

LITERARY NOTICES.

Mr. Standish Motte, the Parliamentary Barrister, has published at the request of the Aborigines Protection Society, a system of registration for the Aborigines of our Colonies, which, although it recommends engineers to be sent out to the colonies, hardly comes within our province; we can say, however, that it contains many profound and original views.

Mr. Wyld, the Geographer, in addition to his national work on the Campaigns of the English Armies in the Peninsula, has recently published several authentic Maps and Plans of the Seat of War in the East.

Mr. Tyas is about to publish a cheap Map of England in shilling sheets, from the graver of Mr. Jobbins, and on the scale of a third of an inch to a mile. From the specimen it seems likely to prove a useful work.

The new Catalogue of Mr. Weale contains the most copious list yet published of works on engineering and architecture.

NOTES OF THE MONTH.

With the rage for promenade concerts, it is scarcely surprising that architecture should have been a little affected with the mania. The Princess's Theatre in Oxford Street, has been opened at present for concerts; it is a gorgeous building in the style of the revival; finished by Mr. Thomas Marsh Nelson; the original design, we believe, being by Mr. Duncan. The ground in Leicester Square, next to the Zoological Society, is being cleared preparatory to a building for promenade concerts.—The Adelphi Theatre has had a new front put on, we believe from the designs of Mr. Beasley. It is a novelty admissible in such a style of decoration, but the pilasters of the lower arch have been unfortunately contracted, from the interference of a neighbour who possesses a right of way.—Oxford Street is being improved by the erection of several new shops on a large scale.—The Architectural Society commenced its proceedings on Tuesday the 3rd.—Mr. Baily has just finished two statues, one of Sir Thomas Brisbane, for New South Wales, and a statue of a distinguished Irish judge for Dublin.—The foundation has been laid of the new Collegiate School at Liverpool.—The British Museum has received several accessions to its Egyptian collections; a fine colossal head has been erected over the doorway, which produces a fine effect.—Considerable stir is being made as to the formation of new railways, but we fear that the Standing Orders will prevent their making much way this Session. Among others we mention, the London and Manchester, the Cambridge and Norwich, through Thetford, the Lincoln and Nottingham, the Devon and Cornwall lines, the Edinburgh lines, one from Mr. Marshall's Slate Quarries to Ulverston.

ON TIDE GAUGES.

Sir,—In your October number you have, somewhat incautiously, given insertion to a letter most injurious to my character, signed "James Inglis, London," on the subject of my new Tide Gauge, a description of which was communicated to the Royal Society by the Rev. Professor Whewell, of Cambridge, and printed in their Transactions for 1838.

Divested of those portions of it which, being merely ornamental, may be safely passed over without remark, Mr. Inglis's letter contains an assertion and an implication, to each of which I must give a separate reply. It is *asserted*, that in answer to various letters which I had addressed to Mr. Mitchell, I received from him a description and drawings of his machine, by the aid of which my own was constructed. In reply to this assertion, I beg to state, distinctly and simply, that I never had the slightest correspondence or communication with Mr. Mitchell in my life, either directly or indirectly, and challenge either him or his friend, Mr. Inglis, to produce one scrap or syllable of any letter of mine in evidence of such correspondence. I may also add that I never saw any drawing or description of Mr. Mitchell's tide gauge, and that I have not, at this moment, the least idea of its principle.

The *implication* contained in the letter of Mr. Inglis is, that as my tide gauge was merely a copy taken from that of Mr. Mitchell, with little or no claim either to originality or improvement, it was not only superfluous but unjust that any description of that machine should have been permitted to appear, with my name attached to it, in the Transactions of the Royal Society. On this latter point I cannot do better than transcribe the document itself which was the immediate occasion of my communicating that description to the public. This document was a letter addressed by Major J. B. Jervis, to the Hydrographer to the Admiralty, Captain Beaufort, R.N., and by him enclosed to me, with the following note:—

"*Admiralty, Feb. 23, 1838.*

"My dear Sir—The enclosed note is from the Engineer Officer who has been appointed to succeed the present Surveyor General of India.—Do me the favour to read it, and tell me how far you can assist us, and when.

"Yours very truly,

"F. Beaufort."

(Note enclosed.)

"To Capt. F. Beaufort.—My dear Sir—I rejoice to say that I have found the Court of Directors disposed to give the fullest effect to our wishes in respect of the registry of the Tides, throughout the whole line of coast of India, and wherever their authority extends. I stated my own views to the Chairman, Sir James Carnac, to Mr. Melville, and other influential persons, and fully explained to them that unless the thing were well done, it were far better let alone; whereupon they directed the dispatch and instructions which they had already prepared for the Governor General and Bombay Government to be withheld, and empowered me to arrange with Mr. Whewell, Mr. Lubbock, and yourself, to propose any course of proceeding and measures we thought advisable, and point out the requisite apparatus. With such a magnificent carte blanche, with such superior co-adjutors, it would indeed be a reproach to be either supine or unsuccessful. Mr. Whewell heartily concurred with us on the importance of having the Tides registered with a far greater degree of precision, and at shorter intervals, at several additional points on the shores of India, Arabia, Persia, the Eastern Islands, and China; and was of opinion that at such stations exact meteorological observations should also be made contemporaneously, and these punctually and promptly transmitted home in duplicate every month, to the Admiralty, to the India House, and to the Royal Society. Although Mr. Mitchell's Tide Guage, erected at Sheerness appears to Mr. Whewell to answer sufficiently well for the subordinate stations, he laid great stress on the necessity of something far superior to this, for those stations where it was intended to have more precise and frequent measurements. He spoke to me in terms of high praise, as did also Captain Washington, of Mr. Bunt's apparatus, but said that he much regretted that it had not been published, although he had been in treaty with the inventor to give it to the public with a complete description." ...... "It is the chief object of this epistle to move you to write to Mr. B. to publish his descriptions and drawings. Do let me urge you to use all your influence with him in so good a cause,—and if he would permit a working model to be made under his own eye, it would greatly assist the native artificers of India and expedite the construction of the several tide gauges. The Directors would readily defray the expense of such model.

"Yours, sincerely,

"J. B. Jervis."

In compliance with this earnest solicitation, I immediately prepared and forwarded to Professor Whewell drawings and a description of my tide-gauge, which were soon afterwards inserted in the Transactions of the Royal Society. In doing so, I acted in opposition to the advice of some of my scientific friends, who thought that I was entitled to secure to myself the fruits of so much labour and study. A few months afterwards I was requested to superintend the construction of two machines, similar to my own, for the East India Directors, agreeably to the tenor of Major Jervis's letter, already quoted; with which request I also complied without hesitation. These machines were completed and intrusted to the care of two scientific officers in the Company's service, Lieuts. Elliott and Ludlow; who, after visiting Bristol for the purpose of inspecting my original tide-gauge, sailed with the two new machines for India in February last. From one of these gentlemen (Lieut. Elliott, who had, I think, seen Mr. Mitchell's tide-gauge,) I have received several letters, in all of which he speaks of my machine in terms of the highest commendation.

Immediately on the appearance of Mr. Inglis's letter, I inserted a reply to it in several of the Bristol newspapers, and sent a copy of my reply to Professor Whewell, from whom I received the following note:

"*Trinity College, Cambridge, Oct. 9, 1840.*

"My dear Sir—I have received your slip of the Bristol Standard, and am full of astonishment at the malignant absurdity of Mr. Inglis. Even on his own letter his conduct has this character; for no amount of correspondence with Mr. Mitchell could have deprived your machine of its vast superiority." ...... "I am glad you have replied to him so calmly. Captain Beaufort's and Major Jervis's letters must satisfy every body, and do you justice."

I now beg leave to request of you, Mr. Editor, that you will write immediately to Mr. Mitchell, and inquire of him what letters of mine he is able to produce in confirmation of Mr. Inglis's statements; whether he acknowledges any friendship or acquaintance with that gentleman; and whether he will favour you with his precise address: and when you have received Mr. Mitchell's reply, that you will be pleased to communicate it to the public.

I am, Sir, your obedient servant,

Small Street Court, THOS. G. BUNT.
Bristol, October 15, 1840.

[In addition to Mr. Bunt's letter, we may ourselves mention that we have written to Mr. Mitchell, and received from him a complete denial that he was ever in correspondence with Mr. Bunt, or that he authorized Mr. Inglis to circulate such statements. In closing this correspondence, therefore, which must be most satisfactory to the claims of Mr. Bunt, we have to express our regret that we should, by the insertion of Mr. Inglis's unfounded charges, have been the means for a moment of raising a doubt as to the originality of Mr. Bunt's invention. We must say that we have never seen a case of grosser or more wicked representation than this by Mr. Inglis, to call it by no other name, and we cannot forbear expressing our severe reprobation of such unwarrantable conduct. We hope that, if he has any feeling of shame about him, he will see the propriety of apologizing as publicly to Mr. Bunt as he has been the means of annoying him.—EDITOR.]

STATE CAPITOL AT RALEIGH, U.S.

SIR—Under the head of AMERICA, at page 52 of the volume of 1837-'8 of your learned work, entitled "*The Civil Engineer and Architect's Journal,*" the *State Capitol* in this city is introduced to the attention of your readers, in an extract of a letter from Ithal Town, Esq., Architect, dated New York, Nov. 3, 1837.

As a Senator, myself, of the State Legislature which ordered its erection, and residing on the spot, I have watched its progress with pride and pleasure, and beg leave to tender to you my thanks and those of my State for even that brief notice of this noble edifice, confessedly unrivalled by any State Capitol in this country. But as I am very sure your readers, and especially artists, would be pleased to see in your Journal a more full and satisfactory description of the building than Mr. Town's letter furnishes, I here copy such a description from the "*Star,*" a weekly newspaper published in this city, and dated 25th March last. It was furnished for publication, at the request of the editor of that periodical, and is known to be from the pen of David Paton, Esq., some years since of Edinburgh, Scotland, the ripe scholar and scientific architect, under whose daily and untiring supervision and direction, for 5½ years past, this great public work has been executed, and is now nearly completed—a work which entitles him to rank among the first architects, theoretical and practical, of this or any other country, and his private virtues and retiring worth, claim for him universal esteem.

I would not, if I could, detract aught from Mr. Town; his professional fame is the property of my country; but then, "let justice be done, though the heavens should fall." I can not, I will not, conceal the fact, that Mr. Town is mistaken when he supposes that the architectural honour of this fine building belongs to him. It is an honour, indeed, of which any artist might be proud, because it is so perfect and durable a monument of his fine taste and great ability. But this honour belongs to David Paton, Esq., and to none else—and it will wear well, because he has earned it well, and left to others and the work itself, to inscribe his name upon the scroll of fame. Mr. Town did, indeed, furnish a draft for the building, and, likewise, most fortunately for the people of this State, engaged the services of Mr. Paton, 10th Sept., 1834, to execute it; but he is probably unaware that his draught was laid aside, and the whole of the details, alterations, and working drawings, made and executed by Mr. Paton himself. But to the description:—

"The length of the State Capitol in this city, (Raleigh) from north to south, is 160 feet, and from east to west 140 feet; the whole height is 97½ feet. The columns of the east and west porticoes are eight in number, and are 5 ft. 2½ in. in diameter, and 30 feet high, and standing on a stylobate 18 feet high, which, as well as the entablature, which is 12 feet high, are continued round the building; and the details are of the Temple of Minerva, commonly called the Parthenon, which was erected in the Acropolis of Athens, under the government of Pericles, about 500 years before the Christian era. The Rotunda, in the centre of the Capitol, is formed into an octagon at top, which is built of polished granite and surmounts the building, ornamented with Grecian cornice, and its dome is crowned at top with a decoration similar to that of the Lanthern of Demosthenes at Athens.

"The interior of the Capitol is divided into three stories. The basement consists of ten rooms, eight of which will be soon occupied by the Governor, the Secretary of State, the Comptroller, and the Public Treasurer; each having two rooms of the same size and finish, which, as well as the corridors, are of the Roman Doric, and are completely fire-proof, by arches springing from pillars and pilasters of polished granite. The east and west vestibules are richly decorated with granite columns, antæ and staircases; all of polished granite, copied from the Ionic Temple of Ilissus, near Athens; also two committee-rooms.

"The second or principal story consists also of ten rooms, two of which are appropriated, one for the Senate Chamber, and the other for the Hall of the House of Representatives, which are 38 ft. 6 in. in height, having galleries, and their walls are contained in areas of the same size, 59 ft. by 55½ ft., having retiring rooms taken off the corners, four in the former, and two in the latter. They, as well as the rotunda and vestibules, are respectively of the octagon Tower of Andronicus Cyrrhestes, of the Temples of Erechtheus, Minerva, Pollas and Pandrosus, in the Acropolis of Athens, near the Parthenon. The other rooms on this floor are appropriated for committee rooms.

"The third, or attic story, contains a room for the Supreme Court of the State, and one for the State Library, which are situated in the east and west wings; which, as well as the galleries and other apartments, will be approached by granite steps, and the lobbies and Rotunda are lit with cupolas; the whole of which is now in progress, so as to be ready for the next meeting of the Legislature.

"Before concluding, it may be well to remark that the stone with which this edifice is constructed is of the toughest and hardest description, containing less iron than any stone I have ever seen; hence it presents a beautiful cream colour, of a much warmer tint than marble. It is also variegated with beautiful veins of quartz, the conformation of which deserves notice, having every appearance of having been separated and again knit, by some trembling or concussion in its formation; and from the circumstance of no petrifaction being as yet discovered, whether of the animal, vegetable, or mineral kingdoms, geologists would term it a primitive, if not a transition, formation.

With regard to the cost of the Capitol; the Legislature have appropriated 500,300 dollars; it may cost a little more by the time it is finished. The President's house at Washington cost, without furniture, 665,527 dollars; and the Federal Capitol cost 2,596,500 dollars, both of which have to be repeatedly painted, at a cost of upwards of 12,000; and this has to be done to prevent the disintegration of the stone, they being built of soft, loose, friable and porous sandstone.

ARCHITECTUS."

City of Raleigh, North Carolina,
United States of America. J. B. HINTON.
22nd November 1839.

RECOVERY OF THE CHAIN CABLE OF HER MAJESTY'S SHIP HOWE, AT SPITHEAD.

THE chain cable of the Howe having by an unfortunate accident run entirely out of the hause-hole on Friday morning last, after the anchor was cast, and fallen to the bottom, a creeper was employed to discover it, which grappled it near the buoy over the anchor. On Saturday afternoon, in compliance with a request communicated by one of the lieutenants of the Howe, Colonel Pasley sent a boat to the spot with Mr. George Hall, one of his most expert divers, and a party of men employed about the wreck of the Royal George, to attend him, who threw out a small anchor near the Howe, and then moored their boat in the supposed direction of the chain cable, by making fast a line from the stern of the boat to that cable's buoy. Mr. Hall then descended by the rope attached to the creeper, by which he found the chain, and from that point walked along the whole extent of the chain until he reached the extreme end of it, to the last link of which he made fast one of the bull ropes that had been used for weighing the fragments of the Royal George, by means of which Mr. Pardo, master-attendant of Portsmouth dockyard, and Mr. Taylor, master of the Howe, with a strong party of seamen and marines, got up the end of the chain cable first into a mooring lighter, and in the course of about two hours afterwards it was passed through one of the hause-holes of the Howe and properly secured. Mr. Hall went down to the bottom about half-past 2, and finished his task about 4 o'clock, and only came up twice in the mean time, to communicate with the men in the boat. It is supposed that he walked at least 200 yards along the bottom, and during this period the boat with the pump, which was constantly at work to supply him with air, being warped along in the same direction, according to signals made by him from below. This is the second time that this excellent diver has been of use to the navy at Portsmouth, having on a former occasion examined the bottom of the Vanguard after she took the ground on being towed out of harbour by the Echo steamer. As this difficult operation required him repeatedly to pass head foremost under the keel of the Vanguard, he performed it in Mr. Siebe's improved tight diving dress, but in recovering the cable of the Howe, which was comparatively an easy task, he used the common diving dress, in which he has generally worked on the wreck of the Royal George, leaving Siebe's dress to the divers of the Royal Sappers and Miners, who have been employed on the same wreck for the last three months, and whom it was desirable to send down in a tight dress, as being the safest, they not having had any previous experience like the professional divers with whom they have been co-operating.

NEW INVENTIONS AND IMPROVEMENTS.

Improvements in Steam-engines and Steam-boilers; patented by Thomas Craddock, of Broadheath, near Presteign, in the county of Radnor, Sept. 16.—The improvements in steam-engines consist, first, in an improved mode of obtaining a rotary motion from the rectilinear and reciprocating motion of the piston rod; and, second, in an improved method of condensing steam.

The improvements in boilers consist in an improved construction of boiler, and in an improved method of regulating the generation of steam.

First claim is to the mechanical arrangement of the apparatus delineated and described, whether employed for converting the rectilinear into the rotary motion, or the rotary motion into the rectilinear. In this improvement the piston rod carries two toothed racks, one being behind, on one side of the other; one of these toothed racks works into a pinion, which pinion takes into the teeth of a drum, which is firmly keyed on the main shaft, which drum has teeth over half its circumference on one side, and over the remaining half of its circumference on the other side. The mode of working is as follows: by the up-stroke of the piston-rod, the pinion, taking into the teeth on one side of the drum, brings it half round, and is released; then by the returning stroke of the piston-rod, the other rack takes into the teeth on the other side of the drum, and finishes the stroke in the same direction.

Second claim is to the exclusive right of condensing the steam or vapour of water, or other liquids, by causing it to pass into metallic tubes of small diameter, or into metallic vessels of any other suitable figure, which tubes or vessels are put in motion, either rotative or otherwise, either in air or water, independently of any motion of the carriage, boat, or vessel, to which the condenser may be attached, whereby the condensation of the steam or vapour is greatly accelerated. This condenser is composed of two chambers, connected by a bar, and supported by hollow axes revolving in bearings, which axes are connected, the one with the eduction pipe of the engine, the other with a hot well or reservoir. From each chamber a number of hollow arms diverge, which are connected together by small tubes, reaching across several times.

The condensing is performed as follows: the steam, after operating on the piston, is introduced through the chamber into the tubes; the condenser is then caused, by bearings from the engines, to revolve with great rapidity, by which means the caloric is abstracted and the steam condensed; the water resulting from which is conveyed from the other chamber, into which it flows, through a pipe into the hot well; from whence it is drawn by the feed pump into the boiler.

Third claim.—The construction and arrangement of the parts constituting the boiler.

Fourth.—The use of a separate cylinder to supply both air and fuel to the furnaces, and regulating the supply of steam to the cylinder by the pressure of steam in the boiler, in such a manner that as the pressure increases, the supply of steam to the cylinder is diminished, thereby diminishing the supply of air and fuel to the furnace. The boiler is composed of two furnaces, the sides of which are formed of ranges of hollow tubes, which are full of water, communicating at the top and bottom with rectangular reservoirs; the bottom is formed of smaller tubes, extending horizontally from one reservoir to the other, and acting as fire-bars; the top is likewise composed of tubes extending from one reservoir to the other; the ash-pit is a tank filled with water, which, by the heat from the fire-bars, evaporates, and passing up a tube into the condenser, is there condensed; thereby supplying any loss from leakage. The fuel is conveyed into the furnaces by shoots from two hoppers; upon being thrown into the hopper, it falls upon two fluted rollers, which are worked by the pinion that drives the fan; it then falls through or between these rollers, and down the shoot upon a swinging plate, which scatters it over the surface of the fire. The wind passes from the fan through a pipe to the bottom of the fire-bars. When the steam gets beyond the regular working pressure, it shuts the valve which supplies the fan cylinder with steam, and escapes through another opening into the atmosphere, whereby the pinion that works the fan is either stopped, or works very slowly, by which means the supply of air and fuel to the furnaces is very much decreased or cut off altogether; when the steam has returned to the regular working pressure, it is again admitted to the fan cylinder, which works as before. There is a suitable opening, provided with a cover, for the admission of the fire, and likewise a tube with an eye-piece of talc for viewing the fire when required. There is likewise a contrivance for burning the smoke arising from the coals when newly thrown on the fire; it operates in this manner—there is a tube which communicates with the two shoots, and at the bottom of each furnace there is a valve for shutting off the supply of air; when one or both of the furnaces have burnt bright, and fresh fuel is required, the supply of fuel and air is shut off from the other one; the smoke arising from the fresh fuel is driven, by the force of the air from the fan, through the flue into the other furnace, where it passes through the fire and is consumed.—*Inventor's Advocate.*

Improvements in the manufacture of iron and other metals; patented by Sir Josiah John Guest, of the Dowlais Iron Works, Glamorgan, Baronet, and Thomas Evans, of the same place. Sept. 28. These consist principally in the introduction of jets of steam into the puddling furnace while the iron is in the state usually called "fermentation." The success of the operation depends very much on bringing the steam in close contact with the melted iron, to effect which, wrought iron telescope tubes, sliding one on the other, are employed, the jet pipe being $\frac{3}{8}$ of an inch in diameter, and the steam pressure 15lb. upon the inch. These tubes are raised or lowered according to the quantity of fluid metal in the furnace, by means of a suitable lever. In the second place, jets of damp steam are introduced into the refining furnace, after the pig iron is melted, through the same apertures as the blast, the quantity and pressure of the steam being regulated by the quality of the metal acted upon. During this process, in order to keep the sides, bridge, and bottom of the furnace from burning, a quantity of steam is introduced upon the fluid cinders as soon as the heat is drawn, until the cinders become of the consistence of paste; this paste is then raked up against the back, sides, and bridge of the furnace, so as to fill up any cavity that may have been burned during the previous heat of iron. The use of cinders in this state keeps the iron quite clean and free from the dirt which always attends the use of clay and limestone. In this instance four jet pipes are used, $\frac{1}{2}$ an inch in diameter, and steam of 20lb. on the inch. The steam may be generated in a tube or cylinder in the furnace chimney, or may be supplied from a regular steam boiler. The employment of steam in a similar manner in melting the alloys of copper and iron, and iron and tin, is also claimed, but the particular application is stated to be to the manufacture of iron, whereby a better material is obtained with greater economy. The claim set forth is for the use or application of steam forced upon or into, or in contact with the melted iron in the refining or puddling furnaces for the manufacturing of the same; also for the similar use of steam in the process of melting or manufacturing alloys of copper and iron, and of tin and iron, in such furnaces; and lastly, the application of steam to fluid cinders as described, to produce the paste aforesaid; and the use and application of the said paste.—*Mech. Mag.*

Improvements in preparing surfaces of paper: patented by Henry Martin, o Morton-terrace, Camden Town. Sept. 30. The processes constituting these improvements, are fourfold, viz.: 1. The mode of preparing surfaces of paper by combining thereon a coating of oil paint, with subsequent embossing as afterwards described. 2. The mode of preparing surfaces of paper in the manufacture of paper-hangings, by combining thereon a coating of oil paint, and afterwards printing or producing thereon the required pattern. 3. The mode of preparing surfaces of paper by combining thereon a coating of oil paint, and subsequently glazing or planishing the same. 4. The mode of producing a coating of oil paint on paper, by means of rollers. The paint used for this purpose is the same as ordinarily employed in house painting; a piece of paper of 12 yards, or other required length, is to be laid upon a table of similar dimensions, sized with one or two coats of common or superior size, and then painted with an ordinary brush; while yet wet, the surface is to be smoothed over with a dry brush, to take out the marks left by the first, and subsequently finished with a badger softener, which produces a smooth and level surface, so essential to the success of this process. In the other process, oil colour is laid on the surface of paper by passing it between two rollers, together with an endless felt; this felt in its revolution is supplied with oil colour by passing into a trough, and under a roller partly immersed in the colour; a scraper removes the superfluous colour as it rises, and levels and equalizes the colour; the paper is passed through the rollers two or three times, according to the thickness of colour required. Paper thus prepared on the surface, may be embossed with engraved dies or rollers in the usual manner, or printed with blocks, &c., for paper hangings, which may be washed with soap and water when soiled. If marbled paper is to be produced, the colours are thrown upon water in the usual manner, the effect being increased by softening off before they are dry. If the surface is to be glazed or enamelled, the oil colour is thinned wholly with turpentine, as a flatting colour; when set, it is to be mounted on a woollen cloth, cotton velvet, or other firm soft bed, and smoothed over with a pallette knife, or trowel having a very smooth surface; when dry and hard, the polish may be heightened by any of the usual methods, which will produce a beautiful surface for copper-plate printing, paper hangings, and various other purposes.—*Mech. Mag.*

Valves for Canal Locks; patented in America by William Lake, Richmond, Virginia, June 7, 1839. The patentee remarks, that "the valves of canal locks are subject to a pressure, the intensity of which is measured by the height of the head and the area of the valves; and this pressure on the common sliding-valves for locks of ordinary lifts is of such magnitude, and requires the application of so great a force to open them, as greatly to de ract from the superiority which they otherwise possess."

"My improvement consists in giving such form to the valves and apertures that, by the momentary application of a very small force in opening a small orifice, I apply the hydrostatic pressure in such a manner as to open the valves. Upon the back of the valves closing the aperture through which the water flows in filling and discharging the lock, I attach a flanch of the same length as that of the aperture, and of such a width as to have the same proportion to the width of the valves as the friction of the valve on the seat has to the pressure. At the lower edge of the valve, below the flanch, I make an orifice of about one inch in width and about half the length of the valve; this orifice I open and shut by means of a lever and connecting rod."

We were about to make further extracts from the specification, but find that in so doing we must occupy more space than is convenient to allow to the subject; and after all, should probably fail to give a clear idea of the construction without the aid of the drawing; we, therefore, skip over to the concluding paragraph.

"I have represented the valve as fixed in a lock-gate, but I by no means intend to restrict myself in my said improvement to valves placed in this particular situation; neither do I claim as my invent on the manner of applying the lever and screw as exhibited in the drawing. What I do claim as my invention, and desire to secure by letters patent, is the application of the hydrostatic pressure, to open sliding valves for canal and river locks, and making such improvements in the construction of the said valves, and in the form of the apertures to which they are applied, as will adapt them to the application of this pressure, as herein described."—*Franklin Journal.*

RAILWAY CAUTION.

Sir,—Being a frequent traveller on railways, and generally choosing the slow trains, I beg leave to trespass on your valuable columns by suggesting an expedient by which, in my humble opinion, travellers situated like myself may avoid the disagreeable necessity of being run over by quicker trains. The plan to which I allude is this:—that at each station on the line of railway be placed a large dial, similar to a clock face, with minutes marked upon it from 1 to 60. It should have one moveable hand of sufficient size to be distinctly visible to the guard and engineer as they fly past; the officer in attendance to fix the hand at that particular number on the dial that may denote the number of minutes which have elapsed since the preceding train passed. This signal might be illuminated at night. Or a perfect clock face might be adopted to denote the hours in addition to the minutes.

I am, Sir,
Your obedient servant,
T. W.

Kennington,
Oct. 24th, 1840.

ROTARY ENGINE.

An engine, upon this principle, was latelytried in Leeds, in the presence of several engineers. Its enormous power, in so small a compass, (the whole machinery, with the exception of the fly-wheel, being contained in a box 2¾ inches in depth and 10 inches diameter) surprised every one present; the speed was tremendous, making from 600 to 700 revolutions per minute. Its power was tested by placing breaks upon the fly-wheel, which was done to the extent that the shaft was actually twisted in two pieces, but no accident occurred. It is the intention of the inventor to apply the machine to propel carriages on common roads, for which purpose it appears admirably adapted; likewise for the purposes of marine navigation, where the small quantity of room it requires is a material consideration; in short, it will answer all the purposes wherein steam is required; and the expense will be considerably abridged. The inventor is Josh. Briggs, watchmaker, of this town.—*Leeds Intelligencer.*

STEAM NAVIGATION.

INCRUSTATION STEAM ENGINE BOILERS.

We are informed by *L'Echo du Monde Savant*, of the 25th of July, that M. Edouard Richard had presented to the Geological Society of France a calcareous incrustation, which must be considered of great value, as it was not formed in the boiler, but in the cylinder of the engine, and beneath the piston. The incrustation formed a disc 12½ centimetres in thickness; and in consequence of the pressure of the piston, it is so hard that it is capable of receiving as high a polish as the densest marble. It is evident, therefore, that explosions may be produced as well by calcareous concretions of the cylinders as of the boilers of steam engines. The engine from which this specimen was procured, has been used for the purpose of pumping water from the mine of Auzin, and has been built after Newcomen's plan.—In *L'Echo du Monde Savant* of August the 5th, we find a communication upon the subject of steam-boiler explosions by M. Flesselle, a retired officer of the French Marine, resident at Graville, near Havre. M. Flesselle suggests, that, in order to prevent the formation of calcareous incrustations, (which have long been considered the principal causes of accident,) some common salt or muriate of potash, should be put into the boiler with each fresh supply of water. M. Flesselle recommends this measure, because the incrustations are formed of the carbonate, the sulphate, and perhaps the phosphate of lime—(salts, insoluble, or sparingly soluble); and these salts, boiled with the muriate of soda (common salt), or muriate of potash, will undergo double decomposition with those muriates; the products being the carbonate, sulphate, and phosphate of soda, and the muriate of lime—salts all of which are soluble.

M. Flesselle says that M. Chaix, of Maurice, has invented a method of preventing explosions, which appears to have been adopted with success in the French government steam vessels; but M. F. considers that auxiliary means also are requisite—and we think he is right; for the fact we have related regarding the engine at Auzin, proves that we should avail ourselves of every cheap and simple aid to prevent the fearful accidents to which incrustations may give rise, seeing that the sulphate, carbonate, and phosphate of lime may be held in suspension by the steam—be carried by it in a state of minute molecular division even into the cylinders—and there also be deposited in the form of hard concretions.—The method of M. Flesselle, seeming founded on correct chemical principles, will, we hope, be put to the test of experience, by some of the numerous engineers of our neighbourhood. We shall feel great pleasure in recording the result.

In England the precaution taken against incrustations is an index of the density of the fluid in the boiler; but this is evidently inadequate—for the calcareous particles are conveyed by the steam into the pipes and cylinder. Perhaps some of our scientific readers will have the goodness to inform us whether the English method of preventing incrustations is identical with that of M. Chaix.—*Gateshead Observer.*

THE PROPELLER STEAM-BOAT.

This vessel was built in the yard of Mr. Dichburn, at Blackwall The engine by which her paddles, or propellers, as they are termed, are worked, was made by Mr. Beale, the engineer, at his premises at Greenwich. She is a small vessel, but very elegant in her proportions, and formed to cut through the water with great rapidity. The engine is of 24 horse power. The propellers differ from the paddle-wheels used by other steamers, in being single blades of iron, only one blade on each side of the vessel, and not a series of blades brought into the water by the revolution of wheels. Each blade is very broad and large, and dips almost perpendicularly into the water, so that the concussion formed by the blades of paddle-wheels dipping into the water at angles is avoided, and the consequent unpleasant vibration of the vessel. Directly the blade dips into the water it is forced back by an arm or limb of iron, performing a motion similar to the leg and web-foot of an aquatic bird, and by means of this motion the vessel is propelled forward. She can perform from 10 to 11 knots or miles an hour. The appearance of the propellers is like that of the legs of a grasshopper, and when in motion their action in some degree resembles the legs of that insect in its walk. One great advantage is, that the propellers occasion no swell in the water, no wake or trough in the river, and no backwater, so that no danger is occasioned to small boats by the rapidity of her progress. This vessel now runs hourly between Blackwall and Greenwich, and appears to be a great favourite, from the number of passengers she is continually conveying backwards and forwards between those places.—*Times.*

Iron Steamers.—Another iron steam vessel was launched from the yard of Messrs. William Fairbairn and Co., at Millwall, on Tuesday the 27th ult., being the second of three vessels for New South Wales, intended for the trade from Sydney to the Hunter's River. She glided gracefully into the water amid the cheers of a number of spectators, and of nearly 600 men who are employed on the premises, and was named *The Thistle.* She is 145 feet long, 20 feet 6 inches beam, and 11 feet 6 inches depth of hold, about 305 tons burthen, and drew when launched only 3 feet 6 inches of water upon an even keel.—*The Rose*, the first of the trio, has sailed for her destination, and she proved herself before leaving the river to have a speed of 13½ miles per hour, and to be one of the strongest and best sea going vessels afloat. The frames of these vessels were much admired on account of their great strength, as well as the manner in which the whole was put together. The engines, which are of 50 horse power each, were also manufactured, and the whole of the fittings executed by Messrs. Fairbairn and Co., within the same premises. The extent of work which was in progress in the yard, and in the engine manufactory, &c., seemed to surprize many of the gentlemen present, who remembered the place in which these operations are now carried on as a piece of marsh land overflowed by the tide little more than four years ago. Within this period the whole of the extensive workshops and iron foundry have been built. Thirty-one iron vessels, to the amount of 6100 tons have been constructed, and steam engines to the extent of 1260 horse power have been manufactured.—An iron schooner intended for the coasting trade from London, and various steam boats, are now in course of preparation, so that it seems this material is making rapid strides in the public estimation for the purposes of ship building.

War Steamer.—It will be recollected that the steamer of war *Polyphemus*, of 800 tons burthen, was launched at Chatham, on Monday the 28th of September, the same day that the *London* of 92 guns was launched, the former vessel proceeded up on the following Thursday, the 1st of October, to the engineering establishment of the Messrs. Seawards and Capel, of London, and they have completely equipped this fine vessel with engines of 200 horses power, with all her fittings, spare gear, implements and stores, and coal boxes of wrought iron to contain 220 tons of coals, in the short space of 22 working days; being the shortest time upon record that a vessel of this magnitude has been fitted. She proceeded down by steam to Chatham on Wednesday the 28th instant, to take in her masts, being quite completed in her machinery; it is considered that it would require a period of six months in any port of

Great Britain to fit a vessel of war of the same magnitude. There were about 220 men employed by the Messrs. Seawards on the vessel; her engines are upon the same system as those of the "Gorgon, Cyclops, Alecto and Prometheus." The "Polyphemus" will be immediately armed with two 10 inch guns, and will proceed directly to the Mediterranean.

Navigation of the Trent.—An attempt is about to be made to revive the steam navigation of the river Trent. There were packets on the river about twenty years ago, but the extreme shallowness of the water in dry seasons between Nottingham and Newark, frequently interrupted the navigation.—*Hull Advertiser.*

Great Western Steam Ship Company.—We understand that some of the experimentalizing Directors of this Company, have resolved on adopting the Archimedean screw for the great iron ship, and are now reconstructing her at an enormous expense, for that purpose. We need hardly observe, that this course has been adopted without the sanction of the Proprietors.—*Bristol Mirror.*—[How many more changes and whims?]—Ed. C. E. & A. Journal.

Steamers in the Pacific.—Extract of a letter from Captain Peacock, dated on board the Pacific Steam Navigation Company's steam vessel *Peru*, lat. 9 15 N., long. 25 50 W., out 14 days from Plymouth:—"The *Peru* has hitherto had a most prosperous voyage, answering in every respect my most sanguine expectations."

Calcutta.—A Company has been formed at Calcutta for establishing two steam ferry boats upon the river Hooghly with chains, upon the principle of Mr. Rendel's floating bridges at Plymouth, Portsmouth, and Southampton; and orders have been sent to this country for their purchase. We have great pleasure in stating, that the contractors are Messrs. Acraman, Morgan & Co., of the Bristol iron works; their competitors having been Messrs. Fairbairn, of London, and Messrs. Jawcett and Co., of Liverpool.—*Bristol Mirror.*

Sicily.—On Thursday, the 15th ult., was launched at Mr. Pitcher's yard, at Northfleet, the *Mongibelle*, a vessel of 500 tons burden, for the service of the Steam Navigation Company, for the kingdom of the two Sicilies. It is intended to fit the *Mongibelle* with a pair of Messrs. Maudslay, Sons, and Field's patent double cylinder engines, of the collective power of 200 horses.

America.—Two large steam-ships are building at New York for the Spanish government, and one for the Russian. Mr. Norris, the engine manufacturer of Philadelphia, has received an order from Frankfort-on-the-Oder for 15 of his best locomotives. Thus American ingenuity in steam machinery is prospering.—*Times.*

Canal Steam Navigation.—The experimental steamer, at present on the Forth and Clyde Canal, was lately docked for the purpose of making certain alterations on the propeller. On the former occasion the floats were fixed at an angle of 45 deg. to the shaft of the propeller, which gave, of course, a progressive motion from six feet in each revolution, the diameter of the propeller being two feet. On the present occasion, the floats were placed on the shaft at a more obtuse angle, so as to reduce the progressive motion six to four feet. On Friday week, the boat was got under way from Lock 16. To conduct to a satisfactory conclusion, of course, the pressure of steam in the boiler was made the same as on the first experiments, viz., 54 lb. on the square inch; and the result of this change in the angle of the floats to the shaft, was found to be an acceleration of speed of 20 per cent., or rather more, as compared with the first experiments. That is, when the floats are placed at an angle of 45 deg. upon the shaft, the speed was found to be five miles an hour; now, when the angle was rendered more obtuse so as to produce four feet progressive motion, it was found that the speed was at the rate of six miles an hour. The result was extremely satisfactory to all the gentlemen present, confirming, as it did, their former anticipations; and the boat has again been laid up preparatory to other alterations which are contemplated, in order, experimentally, to demonstrate the most efficient angle at which the floats should be placed upon the propelling shaft.—*Paisley Advertiser.*

Improvement in Ship-building.—The *Roseanna*, a new ship, lately built by Mr. Jackson, at the South Shore, is the first vessel ever entirely fitted with iron lower-deck beams. They are remarkable for their strength and neatness, and above all, give additional room for stowage, equivalent to 12 inches depth of hold. It is by such practical combinations of wood and iron that we may expect to compete with other nations more highly favoured with shipbuilding; and we advise every man who takes an interest in the "wooden walls" to go and judge for himself. The *Roseanna* lies at the south-west corner of the Brunswick Dock.—*Liverpool Albion.*

ENGINEERING WORKS.

New Aqueduct at Dijon.—It is stated in a letter from Dijon, that the experiment made there of the aqueduct which is to conduct the water from the fountain of Rosoir to Dijon, a distance of 12,610 metres (about 13,700 yards) completely succeeded. Crowds of people assembled on the day the aqueduct was to be opened, to wait for the coming of the water, which was three hours and a half in flowing through that distance.—*Inventors' Advocate.*

The Fleet Sewer, Blackfriars Bridge.—A meeting of the City Commissioners of Sewers took place at Guildhall on Tuesday the 13th ult., for the purpose of taking into consideration Mr. Walker's plan of a culvert at the mouth of Fleetditch, adjacent to Blackfriars Bridge, as a remedy for the very great nuisance occasioned by the want of some scientific application. After some discussion in the committee, the Commissioners of Sewers agreed to the adoption of Mr. Walker's plan of the culvert by a majority of about 15 to 8. The apprehensions so generally entertained of the opposition of the Commissioners of Sewers to the enlightened project of the President of the Civil Engineers, are thus very agreeably and permanently removed.

Herefordshire and Gloucestershire Canal.—A general meeting of the proprietors of this canal was lately held at Ledbury. The report on the state of the works was very satisfactory, the committee expressing their conviction, after a careful survey, that the main part of the line between Ledbury Wharf and Ashberton, upon which the heaviest portion of the works occurred, would be completed within the estimated cost, notwithstanding that the payments for land had been much larger than was expected. The three locks, communicating with the summit level, would be completed before November next, when the trade of the canal would be brought up to the town of Ledbury, from which an immediate increase of traffic was anticipated, and by the end of August, next year, the canal would be opened for the conveyance of goods to the distance of 7½ miles beyond Ledbury, by which extension the trade would, in all probability, be doubled, if not trebled. When it was recollected that the present annual average receipts of the canal, subject as it was to suspension and loss of trade for many months of the year from want of water, was £1,800, the committee anticipated a profitable traffic on the completion of the whole of the works. The estimated expense of the line to Hereford was £76,000, of which sum £45,000 was to be raised by preference shares, and they recommended that the remainder should be obtained by mortgage at five per cent. upon the tolls of the canal. The report concluded by a reference to the completion of the Birmingham and Gloucester Railway, which would open a direct communication with all the large manufacturing towns of the north, and thus operate most beneficially upon the interests of the canal. By the statement of accounts presented to the meeting, it appeared that the receipts amounted to £21,477 5s. 5d., and the expenditure to £21,296 3s. 4d., leaving a balance in hand of £181 2s. 1d. Mr. Ballard, the Company's engineer, read a satisfactory report on the state of the works, the leading features of which are embraced in the statement of the committee. The report was unanimously adopted, and a resolution passed for raising the sum of £35,000, in the manner suggested by the committee. Votes of thanks were then passed to the committee (who were re-appointed for the current year) and to the Chairman, after which the meeting separated.—*Midland Counties Herald.*

PROGRESS OF RAILWAYS.

Dublin and Drogheda Railway.—We are happy to announce that the Dublin and Drogheda Railway Company made their first contract on Friday last. The Messrs. Jeff of Lanarkshire were declared the contractors for the part of the line between the Royal Canal and Raheny, on very favourable terms for the Company, and for an amount less than the estimate of Mr. Macneill, the engineer-in-chief. The competition was a very brisk one, there being no fewer than seventeen tenders for the work, and from some of the principal contractors on the great lines in England and Scotland, as well as from some very respectable Irish Companies.—The parties selected have been engaged extensively on the Ballochine Railway, the Monkland and Kirkintilloch Railway, and have just completed a large work to the amount of thirty or forty thousand pounds, on the Wishaw and Coltness Railway in Scotland. Mr. Hart, a contractor on the Great Western Railway at Box, near Bath, made so satisfactory a tender, and so close in amount to that by the Messrs. Jeff, (we hear it was within five pounds,) that the Directors thought it right, with a view of encouraging such competition, to hand him a gratuity of £50, with an assurance that they will be happy to deal with him on a future occasion.—*Dublin Evening Mail.*

Norfolk, Suffolk, and Cambridgeshire Railway.—Considerable exertions are being made in these counties for getting up subscriptions to form a railway to Norwich and Yarmouth, in continuation of the Northern and Eastern Railway from Cambridge. The latter line it is expected will be opened to Bishop Stortford in June next.

West London Railway.—An adjourned general meeting of the proprietors in the West London (late Birmingham, Bristol, and Thames Junction) Railway Company was held in London on the 12th ult., to receive the report of Mr. R. Stephenson, the recently appointed engineer, on the state of the works. The chairman explained that the report of Mr. Stephenson was not yet prepared, but that the secretary would read to the meeting the report of the directors. It stated that it was proposed to make two extensions of the line, one to the Thames, (the original line stopping short of the river by about a mile and a half,) and the other to Knightsbridge; the extensions to be undertaken by a separate company. The directors calculated that £120,000 would be sufficient to accomplish the object, both companies to be amalgamated when the whole of the works were completed, or as soon after the extension company had obtained an act of incorporation as the proprietors of the two bodies might consider fit. The report was unanimously adopted, as was also a series of resolutions in respect to the mode of issuing the new shares for the raising of the additional capital. It was explained that the amount of arrears due upon calls was £14,437. The meeting adjourned to the 18th November, to receive Mr. Stephenson's report.

Opening of the Taff Vale Railway.—The public opening of the completed portion of this interesting and important line, between Cardiff and Navigation House, nine miles from Merthyr, took place on Thursday the 8th ult. The manner in which the works on the line are executed, drew forth frequent expressions of admiration from the party. The tunnel and viaduct at Quaker's Yard are, indeed, noble specimens of engineering skill; the viaduct across the Taff rises to the height of 120 feet, and is built on six massive [illegible] of the surrounding landscape. The tunnel which passes under Godre-y-coed is 500 yards in length; it was brilliantly illuminated for the occasion, and as the company passed through it, preceded by the band, the effect produced by the echoes of its walls and roof, and the glare of upwards of 2,500 lights, was striking and novel in the extreme. The line is differently constructed from the Great Western, the company having, on account of the number of curves which the face of the country rendered necessary, adopted the narrow gauge, and the rails being laid on chairs affixed to transverse sleepers. The travelling is easy, and will safely admit of a speed of from forty to fifty miles per hour. The carriages, which are admirably constructed, were built by our respected fellow-citizen, Mr. Walter Williams, and the two engines at present on the line, the *Taff* and the *Rhondda*, by Messrs. Sharp, Roberts, and Co., of Manchester.—*Bristol Mercury.*

Further Opening of the Manchester and Leeds Railway.—The first portion of this line, which was opened in July, 1839, was a length of about fourteen miles, from Manchester to Littleborough; and on Monday 5th ult., another portion was opened, to the extent of 27½ miles. This portion of the line commences at Hebden Bridge, about nine miles from Littleborough, and terminates at Normanton, where it joins the North Midland Railway, about fifty miles from Manchester.—*Manchester Guardian.* The *Leeds Mercury*, in noticing the further opening of this line of railway, says,—"We speak on the highest authority when we say, that this railway is the greatest triumph of engineering science over the obstacles interposed by nature, presented by any railway in the kingdom. The high chain of hills which separates the counties of York and Lancaster is only intersected by one valley, namely, the valley of the Calder, and that so narrow and winding, so lined with towns and villages, and so preoccupied by the turnpike road, the river, and the canal, as to make it exceedingly difficult to carry a railway through it. Yet, by embankments and cuttings, by removing rocks and building up arches, by occasionally diverting the river and the road, and often crossing both, by piercing the hills with short tunnels, and taking first one side of the valley and then the other, a line has been constructed not only capable of being worked by locomotive engines, but of being easily and advantageously worked. There are no objectionable curves, and there is not one gradient having half the inclination of those on the Liverpool and Manchester Railway. The line is somewhat circuitous, and this is its only disadvantage; a disadvantage which the speed of locomotive travelling reduces to insignificance. The engineer by whom the line was planned, and under whose superintendence it has been executed, is the celebrated George Stephenson, whose genius and unparalleled works we have so often had occasion to notice with high admiration. Under him Mr. Gooch, one of his pupils, has been employed as resident engineer, and has displayed abilities equal to the execution of the greatest undertakings. The managing director, who has given up his whole time to the superintendence of the work, is Robert Gill, Esq., to whose remarkable energy, zeal, and talent, the company are very greatly indebted for the completion of the work within so short a period."

Birmingham and Gloucester Railway.—The railway from Cheltenham to Gloucester is now completed, or at least one line of rails is permanently laid down through the entire distance, and along these several experimental trips have been made during the past week, with the most complete success. The first of these took place on the 17th ult., and the further opening of the line for the public will certainly take place on the day already announced, viz., the 2nd of November.—*Cheltenham Looker-on.*

PUBLIC BUILDINGS, AND IMPROVEMENTS.

ROYAL EXCHANGE.

This building appears at length likely to be commenced; the following tenders for the foundation were received, and that of Mr. Webb accepted.

Webb	8124		
Grimsdale	8738	6	
Cubitt	8984	14	
Little & Son	9423	1	8
Warde	9586	17	
Piper	9979	16	4
Grissell & Peto	10165	5	4
Lee	10387		
Bridger	10627	6	8
Baker & Son	10932	3	4
Bennett	11181	9	6
Winsland	11302	6	8

The New Riding-house and Stabling in Windsor Park.—This extensive building, the expense of which is to be defrayed by the Parliamentary grant of seventy thousand pounds, is now fast approaching towards completion. Some delay has been occasioned in consequence of extensive alterations in the roof of the stabling on the southern side of the riding-house having been suggested by Prince Albert a short time since. The woodwork of the roof of this portion of the building, which was then nearly completed, was observed by his Royal Highness to be discernible (from the interior) through the windows along the top of the south side of the riding-house; and as this was considered to be an "eye-sore," and highly disapproved of the Prince, the building was unroofed and its height reduced upwards of three feet. The riding-house is one of the most extensive in the kingdom; its dimensions being as follows:—height, 38 feet; width, 52 feet; and its length upwards of 170 feet. The frontage of the whole pile facing the Home Park is nearly 300 feet. Numerous bed-rooms for the grooms and stable boys in the service of Her Majesty have been erected over the riding-house. These are of very small dimensions, many of them not being more than ten feet by nine. Their long line of windows extending the whole length of the roof, and discernible from any point a view is obtained of the building, tends considerably to detract from the beauty and general harmony of the structure. Her Majesty and Prince Albert, who have occasionally visited the riding-house and stables during the progress of the works, have expressed themselves much pleased with the economy of the whole of the arrangements.—*Times.*

Improvements on the Exterior of the Mansion-house.—Scaffolding has been erected in front of the Mansion-house by direction of the General Purposes Committee, for the purpose of repairing the dilapidated masonry which has exhibited itself in several parts of the building, which has been vastly improved in appearance by the frequent application of the Bank water engines. The alteration is so great that the walls actually look in some parts as if they were whitewashed. The figures above the pillars, which had been for many years completely hidden under a mass of soot and filth, are now objects of striking interest. As they are in a measure new to the visitors and even the residents in the immediate neighbourhood, we shall briefly describe them. The centre is occupied by a female figure supposed to represent the presiding patroness or genius of the city of London. She holds in her right hand a spear. Her left hand is resting on a shield sculptured with the city arms. She supports a small sculptured castellated tower on head, and is trampling on a recumbent figure, representing her vanquished enemies. On her right hand stands the Roman Lictor and a boy holding the cap of liberty. The extreme right hand angle of the tympanum is occupied by a representation of the superiority of the British empire on the seas by a large reclining figure of Neptune, with his insignia as God of the ocean; and the spaces are filled up with an anchor and cable, &c. On the left of the centre is another female figure, attended by two boys, bearing the olive branch in her right hand, and pouring out abundance from cornucopiæ with her left; the emblems of commerce occupy the extreme angle on the left side, with casks and bales of goods. It has been considered the more necessary to make all practical improvements in the exterior of the Mansion-house, as the new Royal Exchange will much sooner than it is generally expected begin to show itself.—*Times.*

NEW CHURCHES, &c

Boston Wesleyan Centenary Chapel, erected from the design of Mr. Stephen Lewin, architect of Boston, is one hundred feet long, and seventy feet wide between the walls, and is calculated to seat two thousand five hundred persons. The design of the front is Græco Italian: a flight of steps forty-eight feet long, and a colonnade of Ionic columns in antis, and towers at each end, in which are constructed the grand staircases that communicate with the gallery, having steps five feet long, and landings at each angle five feet square; above the staircase are rooms appropriated to the Wesleyan service. There are two main entrances to the body of the chapel through spacious lobbies, with jib doors communicating with the aisles. The ground floor of the chapel contains three divisions of pews, and the sides are provided with free sittings, on each side of the communion is occupied by the schools; the pulpit is approached by two flights of stairs, at the back of the pulpit are vestries with private entrances to the same. The ceiling is forty feet high from the ground floor, it is panneled with ornamented ventilators at the angles, and a block cornice with panneled pilasters round the gallery, uniform with pannels of ceiling; the divisions and doors of the pews, &c., next the aisles are made of wainscot, framed and moulded; the orchestra is formed at the back of the gallery with private stairs and room for the singers.—The building and ground will cost upwards of eight thousand pounds.

St. Michael's Church, Basingstoke.—Extensive alterations are being made in this edifice, which is a fine specimen of the style of Parochial Church of the reign of Henry 6th. It is being entirely repaired and provided with new galleries, &c. to accommodate fifteen hundred persons. The fittings throughout will be of wainscot. The estimated expense is upwards of two thousand pounds, which has been raised by a liberal subscription in the town and neighbourhood, with the Societies for church extension. Mr. J. B. Clacy, of Reading, is the architect. The church is also undergoing extensive repairs, estimated at fourteen hundred pounds, to effect which a vestry last week empowered the churchwardens to borrow one thousand pounds, in addition to a previous rate of about five hundred pounds. This is an example worthy of imitation by other parishes, where, from a false economy, memorials of ancient ecclesiastical architecture are fast mouldering to decay.

Birmingham.—The ceremony of consecrating the church of St. Mathew, at Ashted, the first of the proposed ten new churches to be erected in the town, took place on the 20th ult., it is a spacious and commodious building of early decorated Gothic architecture, built of brick, with dressings to the windows, doors, &c. of Wedley Castle red stone, and also a spire of the same stone. It contains about one thousand and fifty sittings, including four hundred free seats, without side galleries. It was designed by Mr. Thomas, the architect of Leamington, who very handsomely presented a window of stained glass.

Wolverhampton.—The ceremony of laying the first stone of St. Mary's Church, which, with the parsonage house and school attached, will be erected at the sole expense of Miss Hinckes, of Tettenhall, took place in the presence of a very numerous concourse of spectators, on Thursday last. The endowment, which it is understood will ultimately amount to three hundred pounds, and the site, are also the gift of the same benevolent lady; the total cost of the building is estimated at ten thousand pounds.—*Midland Counties Herald.*

Great Haywood.—The consecration of St. Stephen's Chapel, recently erected on a beautiful site given for the purpose by the Earl of Lichfield, in the parish of Colwich, took place last month. It is of very beautiful construction, and reflects great credit on the taste and ability of Mr. T. Trubshaw, by whom it was designed.—*Staffordshire Gazette.*

MISCELLANEA.

New mode of hanging Pictures.—A very clever and useful invention for the above purpose has been lately patented by Mr. W. Potts, of King William Street, Strand, which we think, as it becomes known, cannot fail of being patronised by all collectors of pictures. The methods of hanging pictures commonly in use are by driving nails into the walls, or running iron or brass rods round the room. Both are objectionable, the former as it damages the decorations, and the latter not only destroying the architectural effect of a well-proportioned apartment, but also that the brackets which support the rod prevent the hooks or cords from sliding to any part wanted. In the patent plan, the means of fixing being above the hooks, they can be moved all round the room with the greatest facility, and necessarily saves much time in hanging or arranging a collection, particularly when any addition is made to it. Attached to the invention are moveable pendant chains and rods, with cross bars and shifting buttons or studs, which can be used or not at the pleasure of the party. Another and very great advantage connected with the plan is, that the rail combines a cornice moulding with the means of supporting pictures, and can be made to form the bottom member of the entablature, as the line in front is not touched either by the hooks, chains, or cord. We cannot but recommend the plan to the notice of architects, as well as to the artist and amateur, as an invention deserving their attention and adoption.

Mr. Junius Smith.—The American papers mention that the degree of LL.D. has been conferred by the University authorities on Mr. Junius Smith, of London, the gentleman whose enterprise, science, and perseverance, have so eminently contributed to the establishment of steam navigation between the old and the new worlds.—*Morning Post.*

Experiment of Large Guns.—On Friday, 11th ult., a party of the Royal Artillery, commanded by Major Chalmers, proceeded to the proof butt in the Royal Arsenal, Woolwich, at 1 o'clock p.m., for the purpose of trying a plan which has been some time in operation in France, for discharging large pieces of ordnance by a hammer and detonating powder, the present system in the British army being with a portfire, ignited and kept burning until the word of command is given. Sir John May, Colonel Dundas, and Colonel Dancey attended to witness the experiment. The gun selected was a 32-pounder, and the charge each time was 10 lb. of powder in a flannel cartridge, with a 32lb. ball fitted in a wooden cup made flat at the end next the powder. Forty rounds were fired, and the simplicity and certainty with which they were discharged gave great satisfaction. The invention is so simple, and might be so easily applied, that there is every reason to believe it will be universally adopted in the Ordnance department. It consists of a small hammer, with a handle about six inches in length, the whole made of brass, acting in holes made in two small pieces of steel fixed by screws to the right side of the gun. The action is given by pulling a piece of cord six feet long, when the hammer falls on the vent charged with detonating powder with such force as to cause instant and certain ignition. There is a small piece of steel to cover the detonating powder, that it may not become wet in rainy weather, and this is so contrived that it falls back the moment the hammer begins to descend.

The New Town of Fleetwood-on-Wyre.—Three years ago there were only two houses at Fleetwood, and the site of the town was a barren waste overrun with rabbits; now there are 103 houses inhabited to overflowing, and 54 in course of erection. It is said that a considerable quantity of land is purchased for building upon, but there is considerable difficulty in procuring a sufficient supply of brick, stone, and lime, consequently building operations are considerably retarded. We may mention, however, that a small but neat church, capable of accommodating about 400 persons is reared, and that the two shore lighthouses, which will be lighted with gas, are in a forward state, one being about 60 feet high, and the other about 12. As the designs are chaste and beautiful, they will be highly attractive objects to strangers visiting the district. A portion of the iron pier head is completed, and the remainder is in a forward state. There will be a shade erected on the pier for the purpose of keeping the goods, as they are landed, dry, and a line of railway will be laid along the pier, with suitable cranes for the landing of heavy goods; and it is probable that these works will, in the course of a month or six weeks, be so far complete as to enable the Company to commence the carrying trade on a great scale, when a considerable increase of trade to the port may reasonably be expected.

French Steam Engine Factory.—The *Armoricain* of Brest, in giving an account of the Government steam-engine manufactory of Indret, says in its present condition it can only turn out three engines of 160 to 220 horse power per annum, but that Government wishes to increase it, so as to enable it to make annually 12 engines of 450 horse power each. The sum allotted to this establishment last year by Government was 700,000f., but it has now been carried up to 2,000,000f. Six slips for building steamers are attached to the establishment; and a war-steamer, the *Gassendi*, of 220 horse power, is at present building here.—*Galignani's Messenger.*

LIST OF NEW PATENTS.

GRANTED IN ENGLAND FROM 1ST OCTOBER TO 22ND OCTOBER, 1840.

FREDERICK PAYNE MACKELCAN, of Birmingham, for "*certain improved thrashing machinery, a portion of which may be used as a means of transmitting power to other machinery.*"—Sealed October 1; six months for enrolment.

THOMAS JOYCE, of Manchester, Ironmonger, for "*a certain article which forms or may be used as a handsome nob for parlour and other doors, bell pulls, and curtain pins, and is also capable of being used for a variety of useful and ornamental purposes in the interior of dwelling houses and other places.*"—October 1; six months.

WILLIAM HENRY FOX TALBOT, of Lacock Abbey, Esquire, for "*improvements in producing or obtaining motive power.*"—October 1; six months.

WILLIAM HORSFALL, of Manchester, Card Maker, for "*an improvement or improvements in cards for carding cotton, wool, silk, flax, and other fibrous substances.*"—October 1; six months.

JAMES STIRLING, of Dundee, Engineer, and ROBERT STIRLING, of Galston, Ayrshire, Doctor of Divinity, for "*certain improvements in air-engines.*"—October 1; six months.

GEORGE RICHIE, of Gracechurch Street, and EDWARD BOWRA, of the same place, Manufacturers, for "*improvements in the manufacture of boas, muffs, cuffs, flounces, and tippets.*"—October 1; six months.

JAMES FITT, Senior, of Wilmer Gardens, Hoxton Old Town, Manufacturer, for "*a novel construction of machinery for communicating mechanical power.*" October 7; six months.

JOHN DAVIES, of Manchester, Civil Engineer, for "*certain improvements in machinery or apparatus for weaving.*" Communicated by a foreigner residing abroad.—October 7 six months.

THOMAS SPENCER, of Liverpool, Carver and Gilder, and JOHN WILSON, of the same place, Lecturer on Chemistry, for "*certain improvements in the process of engraving on metals by means of voltaic electricity.*"—October 7; six months.

THOMAS WOOD, the younger, of Wandsworth Road, Clapham, Gentleman, for "*improvements in paving streets, roads, bridges, squares, paths, and such like ways.*"—October 7; six months.

CHARLES PAYNE, of South Lambeth, Gentleman, for "*improvements in salting animal matters.*"—October 13; six months.

ROBERT PETTIT, of Woodhouse Place, Stepney Green, Gentleman, for "*improvements in railroads, and in the carriages and wheels employed thereon.*"—October 15; six months.

HENRY GEORGE FRANCIS EARL, of Ducie, Woodchester Park, Gloucester, RICHARD CLYBURN, of Uley, Engineer, and EDWIN BUDDING, of Dursley, Engineer, for "*certain improvements in machinery for cutting vegetable and other substances.*"—October 15; six months.

WILLIAM NEWTON, of Chancery Lane, Civil Engineer, for "*certain improvements in engines, to be worked by air or other gases.*"—October 15; six months.

JAMES HANCOCK, of Sidney Square, Mile End, Civil Engineer, for "*an improved method of raising water and other fluids.*"—October 15; six months.

HENRY PINKUS, of Panton Square, Middlesex, Esquire, for "*an improved method of combining and applying materials applicable to formation or construction of roads or ways.*"—October 15; six months.

CHARLES PARKER, of Darlington, Durham, Flax Spinner, for "*improvements in looms for weaving linen and other fabrics, to be worked by hand, steam, water, or any other motive power.*"—October 22; six months.

RICHARD EDMUNDS, of Banbury, Oxford, Gentleman, for "*certain improvements in machines or apparatus for preparing and drilling land, and for depositing seeds or manure therein.*"—October 22; six months.

THOMAS CLARK, of Wolverhampton, Ironfounder, for "*certain improvements in the construction of locks, latches, and such like fastenings, applicable for securing doors, gates, window shutters, and such like purposes.*" Communicated from a foreigner residing abroad.—October 22; six months.

GABRIEL RIDDLE, of Paternoster Row, Stationer, and THOMAS PIPER, of Bishopsgate Street, Builder, for "*a certain improvement or improvements on wheels for carriages,*" for the term of seven years, being an extension of former letters patent granted to THEODORE JONES, of Coleman Street, and by him assigned to the said GABRIEL RIDDLE and THOMAS PIPER.—October 22.

TO CORRESPONDENTS.

R. *We have some suspicion that the Propeller is not new; we will inquire respecting its originality.*

Robertus. *We have not space for the communication he has favoured us with, containing a list of the "Queen's subjects" whose trades are connected with British shipping.*

Ω *We will take advantage of his communication at some future opportunity.*

S. L. *Designs of a Wesleyan Centenary Chapel were received last month.*

Mr. Kingsford's *plan for a Harbour of Refuge at Dover, we are compelled to omit for the present.*

A Constant Reader. *We cannot inform him.*

Architectus. *His communication from America will appear in the next Journal.*

Book received:—Science of Vision.

We have been obliged to defer until next month the Plan and Section of the Reform Club, *in consequence of the artist not being able to complete them in time.*

The next number for December will complete the Third Volume, and will contain the Title, Preface, and Index. Subscribers are requested to complete their sets of the Journal.

Communications are requested to be addressed to "The Editor of the Civil Engineer and Architect's Journal," *No. 11, Parliament Street, Westminster.*

Books for review must be sent early in the month, communications on or before the 20th (if with drawings, earlier), and advertisements on or before the 25th instant.

THE FIRST VOLUME MAY BE HAD, BOUND IN CLOTH AND LETTERED IN GOLD PRICE 17s.

*** THE SECOND VOLUME MAY ALSO BE HAD, PRICE 20s.

DIRCKS' PATENT IMPROVED METALLIC RAILWAY WHEEL WITH WOOD-FACED TYRE.

Fig. 1.

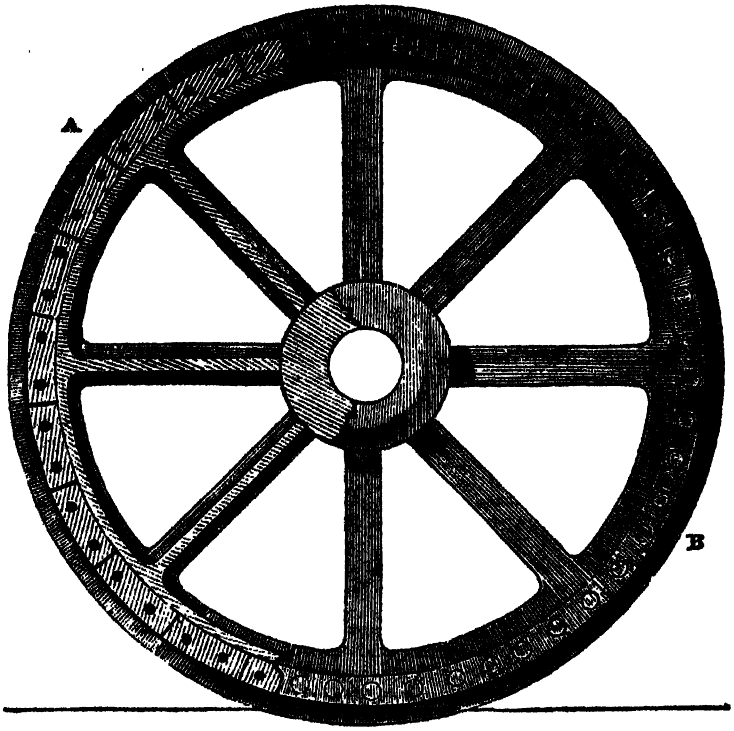

Fig. 2.

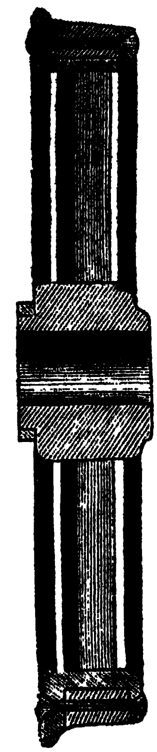

Fig. 3.

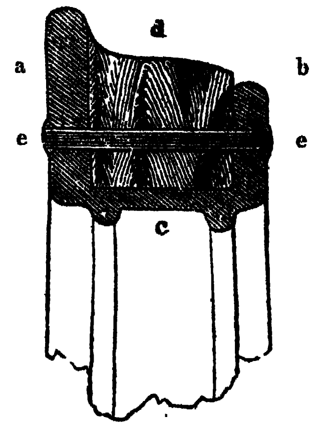

Fig. 4.

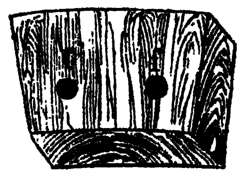

Fig. 5.

DESCRIPTION.

Fig. 1, represents the wheel, half in section, as at A, and half complete, as at B; the view being a front elevation.
Fig. 2. edge elevation, in section.
Fig. 3, showing the channelled tyre *abc*, with the wood inserted at *d*, fastened by the pin or rivet *ee*.
Fig. 4. represents one of the wooden blocks in perspective, perforated with two holes, *ff*, for receiving the pins or rivets.
Fig. 5, cross section of arm of wheel.

Read by Mr. Henry Dircks, before the Mechanical Section of the British Association, at Glasgow, Sept. 19, 1840. And also before the Polytechnic Society at Liverpool, Oct. 8, 1840.

As an introduction to the observations immediately relating to the improved wheel which is the subject of the present communication, a few preliminary observations may serve to make its nature and advantages more generally understood.

Wooden wheels were originally in common use on railways; these were afterwards superseded by the extensive use of cast-iron wheels; and both of these descriptions of wheels were much improved by manufacturing them with wrought iron tyres. Modifications of these wheels are still in use on the Liverpool and Manchester Railway, the wooden wheels having the nave of cast iron, and the spokes and rim of wood, the tyre being of wrought iron. On the London and Birmingham Railway, cast iron wheels are extensively used. On the continent of Europe, and in America, cast iron wheels are seemingly employed by preference; and are no doubt quite as safe for travelling, where great speed is not practised.

In England, a decided preference is given to wrought iron wheels, in which this metal is used throughout, with the exception of the boss being *cast* around the ends of the spokes. The latest improvement on these has been the making of the entire wheel, including the boss, of wrought iron.

The wheels now in general use derive their chief novelty from the construction and placement of the spokes, with a view to obtain elasticity, strength, and durability. One variety which does not come under this denomination, is the plate wheel, supposed on its introduction to possess some peculiar advantage in overcoming a supposed resistance of the atmosphere. Except, however, in relation to variations in size, the present wheels are little more than varieties in pattern. The common diameter of carriage and waggon wheels is three feet, and the largest driving-wheels for locomotives are those employed on the Great Western Railway, being six to seven feet in diameter,—though at one time they were made as large as ten feet.

The action of an iron wheel on an iron rail, though derived from a rolling motion, can only be compared to a series of blows, and the rebound occasioned by iron striking iron is well known to be considerably greater than is produced by striking wood on iron. To this simple fact we may trace the tremulous motion occasioned by iron wheels on an iron railroad; and when, by any trifling accident, as an inequality from the rising of one end of a rail, or sometimes even from small flinty pebbles getting on the rail, the rebound is not more fearful than dangerous. The tremulous motion of the rail just adverted to renders it necessary in most cases to lay the rails on wooden sleepers. As an illustration of what is meant, it may be mentioned that on the Dublin and Kingstown Railway the rails were originally laid on granite sleepers, but the tremor was so great as to loosen the rails, and occasion serious fears from the consequent damage sustained by engines and carriages passing along the line. It was, therefore, ultimately agreed to take up the granite and lay down longitudinal wooden sleepers, a work of considerable labour and expense. In some cases the nature of the soil or sub-soil may allow the use of stone blocks; and where they can be applied with safety, they are preferred, for the reason that a road laid on *stone* blocks can be kept up at a lower rate than one laid on *wooden* sleepers; and, as has been endeavoured to be clearly shown, the only reason for laying the stone aside, arises from the tremor imparted to the rail by iron wheels as at present used. Brees, in his Railway Practice (1839), gives, in a copy of an estimate for work on the "North Union Railway," the following particulars, at page 142:—

Maintaining railway crossings and sidings, when laid on stone blocks of five cubic feet, for the first year, per mile		£150	0	0
Ditto ditto second year		80	0	0
		£230	0	0
Ditto, on larch sleepers, for the first year, per mile	£200 0 0			
Ditto ditto second year	120 0 0			
		£320	0	0

We shall now proceed to a description of the improved metallic wheel with wood-faced tyre, showing its advantages in connexion with the preceding observations. The construction of the wheel may be understood by imagining a spoked wheel with a deep channelled tyre. The wheel may be made either of cast or wrought iron, it having been ascertained that tyre bars can be rolled to the required pattern. In this channelled tyre are inserted blocks of African oak, measuring about four inches by three and a half inches, solidified by filling the pores with unctuous preparations; thereby counteracting the effects of wet by capillary attraction,—to which, by this means, it becomes impervious, and at the same time is not liable to unequal contraction and expansion. The blocks of wood are cut to the requisite form to fit very exactly in the external circular channel of the wheel, with the grain placed vertically throughout, forming a complete facing of wood, as shown in the engraving. There are about from twenty-eight to thirty of these blocks round each wheel, where they are retained in their place by one or two bolts passing through each, the two sides of the channel having corresponding holes drilled through them for this purpose: the bolts are then well rivetted. After being so fitted, the wheel is turned in the usual manner. The wheel when finished has all the appearance of a common railway wheel, but with a rather deeper rim, the tyre faced with wood, and the flange of iron. Woods of various qualities may be used, whether hard or soft, requiring different chemical preparations according to their porosity, and in some instances requiring to be compressed.

The several advantages which this wheel possesses, are—

1. That the wood facing will wear a considerable time without requiring any repair.

2. That the wood can be refaced, by turning it up again in the lathe, as practised with worn iron tyres.

3. That the tyre can be re-faced with wood at little expense, and at a far less loss of time than usual. In the operations of re-facing these wheels, or putting in new wood, the work can be performed without the labour and cost of removing the wheels from the axles, which in the keying and unkeying is known to be very troublesome.*

4. That, in regard to their working, it is the opinion of practical engineers, confirmed by actual experiment, that they will work smoother, easier, and, as some have expressed it, more "sweetly" than iron-tyred wheels; with the advantage of going well in wet weather, even upon inclines,—having sufficient adhesion to the rail, without dropping sand to assist them in this respect, as practised when iron wheels are used.

5. That another and very important result will be, that the rails themselves will suffer less wear by using this kind of wheel, and that the fastenings, sleepers, and blocks will receive considerably less injury, and thereby favour the laying of railroads on stone blocks, wherever they are considered to be most desirable.†

A metallic wheel with a wood-faced tyre, which is the principle of this construction, obviates most, if not all, the difficulties which have been experienced, whether in the use of wooden, cast iron, or even wrought iron wheels. Cast iron wheels may, indeed, now be considered not far short of being equal to wrought iron wheels, for safety and durability, with all the superiority of which the application is susceptible. They are also neither clumsy nor inelegant in form, and are capable of being made to any pattern, even for carriage wheels for common roads. It may, therefore, very possibly occur that they will have the effect to bring cast iron wheels into as general use, and as much reputation here as on the continent. This new construction and simple adoption of wood makes excellent driving wheels for locomotives; it may be readily stopped by using a cast iron break, and does not undergo that wear which might be expected from the friction it then has on the rail. The wood, by use, becomes exceedingly close and firm, acquiring a surface not easily distinguishable from metal in appearance.

These wheels are manufactured by Messrs. Brockleburst, Dircks, and Nelson, millwrights, engineers, and iron-founders, at their works, No. 12, Oil Street, Liverpool; where they may at any time be seen.

* As in every thing affecting railways, it is a desideratum to decrease the expense as much as possible, it may here be mentioned that three feet cast iron wheels, with wood-faced tyres and wrought iron axles complete, can be made much cheaper than the generality of wheels.

† On lines situated like the Greenwich Railway and the Blackwall Railway, wood faced wheels would diminish much of the noise which at present is a source of general complaint.

CANDIDUS'S NOTE-BOOK.

FASCICULUS XX.

"I must have liberty
Withal, as large a charter as the winds,
To blow on whom I please."

I. After "*But*," the most provoking word in the language is your "Only"; which is employed extenuatingly to apologize away, as it were, the very sum of complaint, as being a mere trifle, too insignificant to be taken into the general account. This or that building may have *only* such or such defect, and of course you run the risk of being set down for a very ill-natured, or an exceedingly fastidious hypercritical sort of person, if you object to it on such account, even though it should be of such nature as absolutely to cancel all other merits and recommendations. There are cases in which a single defect may be a fatal one; I might instance this directly and architecturally by referring to buildings which furnish cases in point; but it may be illustrated by the anecdote related somewhere, if I mistake not, by Theodore Hook, of the Adonis who had only a single blemish. In every other respect his person and countenance were unexceptionable. His mouth, teeth, hair, eyes, hands, were all allowed to be perfect, and were expatiated upon by a friend so eloquently that a lady fell in love with his description, and desired that the original might be introduced to her; on which the other thought fit to hint that he had omitted one slight imperfection in the portrait he had drawn, but it was "only a single blemish," a mere trifle, absolutely, in comparison with the loss of an arm or a leg. "Oh! some scar, I suppose—perhaps a wart?" inquired the lady; "an unlucky wart, perhaps, on the tip of his nose." "A wart on tip of his nose! Bless your heart, no! for the truth is, he has—*no nose at all!* which little defect is the one I alluded to."

II. It is precisely such "little defects" and slight blemishes that mar so many buildings and works of architecture. They have—in description at least—a host of merits; columns *comme il faut*, Doric or Corinthian, unexceptionable proportions, amplitude of dimensions, solidity of materials, &c., are expatiated upon till you raise your expectations almost to the highest pitch. At length you discover that the "slight defect"—the "only fault"—should any have been hinted at, renders the anticipated piece of perfection very much in the same plight as the Adonis with the single blemish—the Adonis without a nose.

III. When people begin to be sick of the everlasting boring and twaddling about styles, they will then, perhaps, begin to find out that quite as much or more depends upon the application of a style, as upon its merits as such. For what are the different styles of architecture, but so many different languages of the art—some of them more perfect, more expressive than others; but the excellence of a language, and the excellence of a composition in it, are quite distinct matters. The same language may be the vehicle of wit or of stupidity; and so also may the same style of architecture be employed tastefully or uncouthly; by one so as to charm and delight, by another so as to excite only ridicule and disgust. Which being the case, of what practical value are all those superficial, vague, and wearisome discussions from time to time on the subject of styles, in which not a single idea is brought forward that has not been repeated times innumerable before? On no other subject would such mere school-boy stuff be endured, much less pass for any show of learning, as is *parroted* in regard to architecture. Many prate most glibly about the age of Pericles; yet ask one of those erudite, sagacious gentlemen, what he thinks of that age in its chryseo-elephantine works, and architectural polychromy, and ten to one but he will be struck all of a heap; he wonders what *elephants* have to do with the matter, nor did he know before that Pericles had a daughter named *Polly*.

IV. The fact is, we are apt to judge of styles as we do of national or of professional character—in the lump; which, though a most expeditious and convenient, save-trouble mode, not unfrequently leads into dreadful blunders. The French are a lively people, yet shall you find Frenchmen of most excessive dulness and stupidity. You may stumble upon honesty in the shape of a lawyer, on temperance in that of an alderman, and on perfect good-nature in the person of a sarcastic satirist.

V. In an article in the Gardener's Magazine for November occurs the following bit of architectural comment: "in returning we observed two frightful chapels; the Hanover Chapel at Peckham, in the form of a pentagon, with small mean windows without facings, and red brick walls without cornices or any decoration whatever: and another chapel nearer Camberwell, of larger size, with similar walls. and *three or four stories* of naked windows like those of a third-rate dwelling-house! Chapels in general, throughout the country, are at present *a disgrace* to it, in an architectural point of view; but it is to be hoped that the spread of knowledge and taste will raise them to a par with other religious buildings." Yes, our chapels—and *churches*, too—generally are a disgrace to the country, as well on account of the beggarly, shabby, sordid meanness, as for the execrably bad taste they display. But as for the good taste that is to lead to a better system of things, where is it to come from? Certainly not from the fountain head—not from the Church Commissioners. However, I will not be quite sure that even brick boxes, with three or four stories of sash windows, are not a degree more endurable than those most trumpery *Gothicisings* or *Grecianizings*, as the case may be, which spring up like mushrooms in the purlieus of Islington, &c., and whose scanty pauper finery forms a contrast no less ludicrous than woful, with the bareness of their posterior parts. Economy is excellent, but the economy which treats itself with a smart shirt front, while it denies itself a pair of breeches, cannot possibly be extolled for its nice attention to decency.

VI. If I am rightly informed, more than one of the Islingtonian buildings alluded to is the joint production of two architects, in which case, to judge from the littleness of their united taste, the taste of each singly must be exceedingly little indeed. Or, would not the rather stale anecdote of the two helpmates come in here most pat? "What are you doing, Jack?" "Nothing, sir." "And Tom, what are you doing there?" "Please, sir, I'm just helping Jack." It was undoubtedly after some such fashion that the Messrs. Tom and Jack there employed *assisted* each other in providing taste for the Islingtonians. Certain it is that taste fares no better among Church Commissioners than among their worships the Churchwardens.

ON THE ORIGIN OF ALPHABETIC WRITING ON MONUMENTS, TOMBS, &c., IN ANCIENT GREECE.

Amongst the many pleasures connected with historic research, may be recorded that which the antiquary feels, as the evidences of some lost truth unfold themselves to his eye. To find how link after link completes the chain, or how the past is restored to observation after a lapse of centuries, is no less interesting, however, to the architect, the painter, and the sculptor, whenever the purposes of art are assisted by such a discovery. With this preface of apology for discussing the present subject, I humbly offer my opinions, with the unpretending wish only, that it may lead to a deeper attention from others. My idea of handling the theme arose from a remark of Canina's upon some ancient tombs found at Cœre, (now Cervetri, or Ceveteri). His remark is embodied in a paper, read at the Institute on the 30th March, 1840. He concludes from the peculiar form of the Greek characters of the inscriptions, that the tomb must have been erected before the Trojan war. Now the Trojan war is an event—an epoch in history. It encompasses within it a variety of interesting facts, customs, manners and rites. To determine the existence of alphabetic writing, as existing on monuments and tombs, before or after that period, is no less interesting; especially as in the investigation we trample on the memory of the honoured dead; for whom art has done and expected so much, and for whose deeds and memorable acts, genius has prepared such monuments of beauty and of skill.

Canina evidently presumes alphabetic writing as common to the tombs of the great before the Trojan war. With submission then to his opinion, as well as to others, who I know agree with him, I will assume the contrary, and endeavour to prove it of a later period.

First, I rely greatly on the authority of Homer, on the minuteness, care, and correctness of that poet, on his punctilious observance of customs, and on the extreme finish of his descriptions. Assuming this, I turn to the tale of Βελλεροφον (Iliad 6th, 168), not to disprove the non-existence of letters, &c., but to reveal Wolfius a German commentator upon Homer, guilty of the same idea as myself, since upon that tale, he presumes alphabetic writing unknown in the heroic ages. Secondly, our introduction to Patroclus's tomb, has no mention of any inscription, or written memorial. Thirdly, that the word γραφειν of such frequent occurrence, according to Guoquet, "ne signifie jamais chez Homer que representer ou decrire un objet." Fourthly, that wherever commands are given, or messages sent, they are done verbally; and whenever a treaty is ratified, it is done by sacrifice, or oath. Then again, Virgil's careful picture of Misenus's death and burial, and of the tomb erected, &c., mentions no inscription, which strengthens the argument, when we consider that Enœas is trying to pacify the spirit of that hero in the infernal regions, with a minute detail of all the honours and tributes paid to his memory. To omit one observance, would display a carelessness totally at variance with an otherwise ingenious recital.

Besides no nation was ever more jealous than the Greeks of funeral honours. The advantages of an illustrious victory were often neglected to perform this duty. Victorious generals were sacrified for want of zeal in burying the soldiers slain in battle; whilst the auguries they derived from, and the vows they made over tombs, evince with what earnestness, the depositaries of the precepts of religion, had ever recommended the duties of the sepulchre. But perhaps it may be said that Guoquet in his work "sur les origines des lois, des sciences et des arts," admits the existence of alphabetic writing in Greece before the Trojan war. If so, let it be remembered, he adds, "that it was less practised." Besides if Guoquet were correct in his supposition, the knowledge of letters as a medium of conveying thoughts through the body of the people, must necessarily prove tardy and progressive. And although we believe it in existence at the time of Cadmus, still a natural inference would be, that the priests, as in ancient Egypt, were for a long time alone familiar with the written or descriptive language. The fact, too, that the Mexicans and Peruvians had attained to a great degree of civilization, without the use of letters, may assist such an idea.

The question then naturally arises, how, if inscriptions be to memoralize worth, or to record virtue, and how, if the knowledge of letters be assumed as slight, partial and confined, could the object be effected; or why would the artist chisel out in letters, the deeds of the departed, when most of the passers by were unable to interpret. Upon these grounds I humbly dispute the remark of Canina's: and I do so, not for the bare love of agitating subjects, which but for the curious and ingenious, would be contentedly dismissed, as unworthy and trivial; but from an anxiety to arouse the slumbering energies of the artist, and to invite a cool and rational enquiry into the antiquities, literature and minutive of his art.

Frederick East.

November, 1840.

DESCRIPTION OF THE HYPSOMETER.

An Instrument invented by John Sang, *Esq., Land Surveyor, for taking the Heights of Trees, Buildings, and other objects. Communicated by* Mr. Sang, *Land Surveyor, Kirkcaldy.*

(From the Gardeners' Magazine.)

I have taken the first leisure hour to make you the instrument for measuring the height of trees and buildings which I mentioned to you when having the pleasure of visiting you at Bayswater. It is sent by post at the same time as this letter.

The instrument was tried on some houses and trees here, and it gave their height (especially the houses) with great accuracy. It is rather difficult to manage at first, but after a few trials it becomes quite easy. The method is as follows:—

By means of a small hook (if a knot of white cloth be attached to it, so much the better), fix the end of a tape line to the bole of the tree, at exactly the height of the observer's eye from the ground. Retire from the tree, letting the tape line unwind until, by using the instrument, the top of the tree and the end of the tape line are seen quite close together. Add the height of the observer's eye to the length of the tape line, and the sum is the height of the tree. Now, the difficulty is, to catch the image of the top of the tree in the instrument, and it is this which requires a few trials, although any person who has been accustomed to use a sextant will do it at the very first. Hold the instrument at one of the milled ends, taking care that the fingers do not project over any of the holes, and that the brim of the hat is out of the way. Apply the eye to the round hole marked *a* in fig. 1, and look through in the direction of the small square hole *b*, the instrument being held so that the line joining *a b* is about level, while the large square hole *c* is turned towards the sky. You will then see some object directly through the small hole, and at the same time the image of some other object, the light from which enters the large aperture, and, after being reflected by the two mirrors inside, passes into the eye. Whatever two objects are thus seen in contact, subtend at the eye an angle of 45°, as in fig. 2; so that, if one of them be the end of the tape line on a level, or nearly so, with the observer's eye, while the other is the top of a tree, supposed to be growing straight up, the distance from the eye to the bole of the tree will be exactly equal to the distance from the end of the tape line to the top of the tree.

Fig. 1.

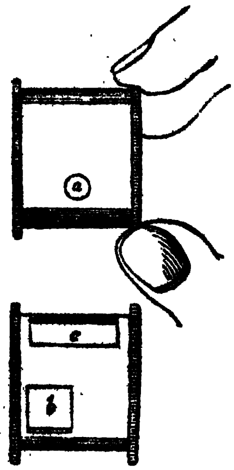

Fig. 2.

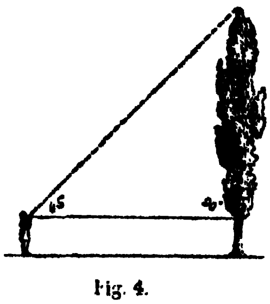

Fig. 3.

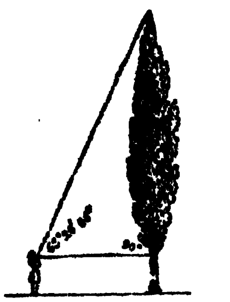

Fig. 4.

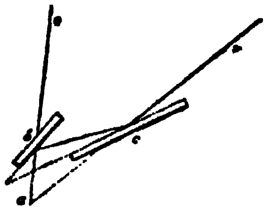


You will thus observe that the accuracy of the measurement depends on the tree being erect from the ground. On sloping ground the measurer would require to go out from the tree in such a direction that the tape line was perpendicular to the stem, but this could be judged sufficiently well by the eye to give the height, of even a very high tree, nearly correctly. The heights of those houses I tried were given within an inch, which was no doubt owing to their being perfectly upright on a level court yard.

The principle of the instrument is quite simple, being exactly the same as that of the sextant or quadrant, only that the mirrors are fixed at a certain angle instead of being movable. Thus, in fig. 3, *a* is the eye, *b* a mirror partly silvered, and *c* a larger mirror wholly silvered. A ray of light *r*, falling on the mirror *c*, is reflected from it in the direction *c b*, and again reflected from the mirror *b* in the direction *b a* to the eye; at the same time another ray of light comes from an object *o* direct to the eye at *a*, without being reflected. From the nature of reflected light, the angle *r a o* is equal to twice the inclination of the mirrors, and is constant, however much the whole instrument may be moved in the plane of the objects, as you will easily perceive by catching the reflection of the candle in the instrument, and moving it in the plane of the milled ends.

I am sure this very portable instrument will be useful for measuring single trees, or buildings, which are as far asunder as they are high, but I am afraid it will not work well in a close wood, on account of the operator not having room to retire as far from the trees as their height. If this is found to be the case, the remedy is to construct another instrument in which the mirrors are placed so as to give an angle of 63° 26′ 05″. In this case the height of the trees will be equal to twice the length of the tape, added to the height of the observer's eye. (See fig. 4.) Of course a small deviation from squareness in the trees and tape line will make a greater error than with the instrument sent, bnt still it will give a result near enough for all practical purposes.

I have only to add, that the mirrors are made of common window glass selected as the most even from among a great many pieces, bnt still they are not quite flat. I had some glass from London perfectly true and flat, but so dim and badly polished as to be unfit for use.

Kirkcaldy, Jan. 31, 1840.

Postscript in Answer to some Questions asked of Mr. Sang by the Conductor.

The instrument for measuring the height of trees is not a pocket sextant, like that of Mr. Blackadder, mentioned in vol. xiv. p. 257, although nearly allied to it. The sextant, quadrant, reflecting circle, improved Wollaston's goniometer, as well as the optical square and tree-measurer, are all varieties or improvements on Hadley's first invention. The two latter differ from the rest in the mirrors being permanently fixed at angles suitable for the purposes for which they were intended. The pocket sextant would measure the height of trees quite as well, but, being expensive, and requiring some skill to use it, it is not likely to be much employed for such purposes. There is no sort of merit in designing the instrument; and is so exceedingly simple, that I have no doubt the idea of modifying the sextant, so as to make it readily measure the height of trees, has occurred to many a one. I, however, never heard of such an instrument, and believe that the one you have is the second of its kind in existence. The other is one which was made for yourself. My father was so much pleased with it that he asked me to make one for him, which turned out neater than the first, and accordingly I sent it to you, as being the better of the two. As there is nothing like a Greek name for giving identity to it, you might call it a dendrometer, or, better still, a hypsometer (measure of height).

Of course any instrument maker could supply these articles; the price, I should think, would be about 20s. each. If there were any prospect of selling a dozen or two, I could easily employ a workman here to make them, and they might be sent from the seedshop to any place by post.

Kirkcaldy, Feb. 18, 1840.

BRITISH MUSEUM.

Sir—That the British Musenm is a *monument*—as the French term it, which does honour to this age and country, is what, for peace sake, I will take for granted, notwithstanding that I myself perceive nothing particularly monumental or dignified in the sulky and barrack-like aspect of the exterior of the new buildings. No one, indeed, can deny that the most frugal economy has been observed there—of course a very plain proof with what rigorous conscientiousness the cash is uniformly doled out of John Bull's public purse. Still there are illnatured grumblers who opine there are occasions when liberality bespeaks more prudence than cheese-paring economy, and is the more becoming virtue of the two; and that such an edifice as the one I am speaking of, ought to be in every respect a finished piece of architecture. Possibly, the façade—whenever that comes to be executed—may make some amends; yet it surely would have been better that the whole should be of a piece, and not like Dick Wilson's fine embroidered waistcoat, with its 'back-front' made out of one of his own picture-canvasses. It may be very true that the rest of the building is not intended to be seen, but still as it is not screened from view, it is rather hard to tax the imagination of matter-of-fact folks like myself, so far as to tell us we are to imagine we do not see what is staring us in the face, nor to give credit to our own eyesight. Upon such notable principle of economy, the backs—I mean the East end of St. Paul's, might have been left a plain brick wall; but it seems Sir Christopher's notions of economy were very different indeed from those of Sir Robert.

I find I have rather committed myself, for what I have been saying is likely to call the sincerity of my first sentence, terribly into question. No matter; it can't now be helped; and only proves that liars and critics ought to have good memories. Accordingly my willingness to 'take for granted' and so forth, must now either be set down as a palpable *hum*, or be imputed to my considerate forbearance in not discussing the architectural merits and demerits of Sir R. Smirke's edifice. I will not inquire whether the taste he has shown in the interior of the building is such as to indemnify us for its excessive homeliness without; nor whether he has been prodigal or economical in drawing upon his fancy and imagination. But I will say that however much he may have consulted convenience rather than splendour, or may have succeeded in combining both, in other parts of the plan, he has attended to neither the one nor the other in the Reading Rooms, which are about as inconvenient for the purpose as could well have been devised,—to such a degree that without taxing our fancy very much, we might fancy no instructions respecting them had been given to the architect, and that when it was afterwards discovered that the Book-makers and Novel-readers who frequent the British Museum, must be put somewhere, they were *accommodated* where they are now crammed. "Remuneration means five farthings," and in the present case accommodation means being left to shift as well as you can for yourself, and perhaps be forced to sit in dim-twilight—where if you cannot see to read, you may at least sit and muse,—which of course looks solemn and meditative, and is highly becoming in a *Muse*-um.

This is no exaggeration of mine, since it is hardly possible—except, indeed, for literary *owls*—to see to read at any of the tables on the window-side of the West room, in dull weather; those windows being at a considerable height from the floor, and there being no others at either end. Consequently one-half of it is so imperfectly lighted, that were it a church people would grumble at it as a dismal dark hole, where they could not see either to hear the sermon, or to study the newest fashions of the congregation. There may indeed be some who can see to read by their own inward light; but the generality of people will perhaps agree with me that apartments not intended merely as libraries, but as *public* reading-rooms, where instead of seating themselves just where they can see best, people must be content with the best vacant places they can find,—that such apartments should be sufficiently and uniformly lighted, so that every part should be equally commodious in that respect.

It would have been infinitely better to have had for the purpose, rooms less lofty, and lighted entirely from above, with a clerestory lantern along the centre, and skylight compartments along the sides, so as to diffuse the light as equally as possible every where. But, it will be said, it was quite out of the architect's power to do this, there being an upper floor: yet it was surely then matter for consideration whether it would not be more eligible to convert the present rooms to some other purpose, and make use of one of the upper galleries (lighted from above) as Reading-rooms. The extra trouble of having to ascend higher in order to reach them, would be amply compensated by their greater comfort and commodiousness,—for their present length might then have been considerably extended. Perhaps it will be objected—for *buts* and objections are always plentiful enough—that this would have been attended with one serious inconvenience,—namely, the distance from which books would have to be fetched were the Reading-rooms not upon the same floor as the Libraries. Yet that difficulty would be at once obviated by having a *lift* or shaft (as many as might be requisite), close by the bar where the books are delivered; and by means of which a whole cargo—if requisite, might be raised equally expeditiously and easily.

There are, however, other inconveniences in the present rooms that ought to be remedied. One is that the space is by much too confined, for either the tables ought to be nearly double their present width, or there ought to be seats only on one side, for when a person has—which is frequently the case—very large folios before him, they occasion inconvenience both to his opposite neighbour and himself: besides which sufficient space is not allowed between one sitter and another, should they both happen to have many books or very large ones by them.

Were it not that it might be deemed a piece of shameful extravagance, I would hint that it would not be amiss if a few yards of drugget or matting were purchased to lay down along the centre avenue of the Reading-rooms, in order to deaden the noise of persons perpetually passing to and fro on the stone pavement there. By way of providing the ways and means for raising the sum required for buying the said drugget, I would recommend that the open wire-work doors now enclosing the bookcases in those rooms should be taken off their hinges and sold; because so far from being of any use, they are merely a very great nuisance. Being unglazed they do not protect the books from dust, neither are they any protection whatever against plundering—if such be their intended purpose, because those cases—which contain books of reference, journals, dictionaries, &c., are accessible to any one, as he may have as many as he pleases opened in turn, if he summons the turnkey attendant, and as when once opened the cases are left unlocked, there are always several from which persons can take down books. There are, besides, always piles of books on the tables, from which a person frequenting the Museum for such a purpose, might filch away any pocketable volume, though even then he could not pawn it without first mutilating it, by tearing out the Museum stamp-mark. Therefore in the way of precaution against filching books, the doors to the cases in the Reading-rooms are quite nugatory—a mere idle show of carefulness and security. In themselves, however, they are a nuisance, not only as imposing needless trouble and bustling about, to both attendants and visitors; but because they are actually in the way when opened, while persons are referring to the books, there being then no room for other people to pass between them and the tables. If, therefore, there must be doors to those bookcases, the tables ought to be shortened two feet, so as to allow greater space between the ends of the tables and the walls. I will not now speak of the Catalogues except to say that I believe they are blessed undevoutly backwards, every day and all day long. Neither will I now touch upon the literary wealth of the Museum in those departments which are most likely to interest your own readers, it being utterly impossible to do justice to either topic at the fag end of my present letter; I must, therefore, reserve them for another. That some improvements have taken place of late years I do not deny, but still the Museum requires a good deal of poking up, before it will be placed upon the footing which it ought to be.

I remain, &c., &c., &c.,

JOHN [but not John Wilson] CROKER.

P.S. I forgot to remark that had the Reading-rooms been on the floor above that where they now are, namely, on the first floor from the sky, they would have been much more in character, for the votaries of literature have always greatly affected the upper regions of buildings—vulgarly termed garrets—for their abodes.

SURVEYING.

REMARKS ON THE NEW SCALING INSTUMENT.

SIR—The last number of your Journal contained a letter from "An Old Surveyor," in which, speaking of the New Scaling Instrument recently introduced at the Tithe Office, and extracted from my *Treatise on Engineering Field Work*, into your Journal for October, he remarks "that I must have been misinformed when I stated that the principle of the plan had long been known to some few surveyors, &c., and also believing that I did not wish to deprive the inventor of his due share of credit, to state who were the parties acquainted with the principle of the plan, prior to its introduction at the Tithe Office." From the courteous—not to say complimentary tone of your correspondent's letter, I feel much pleasure in affording him the requisite information. By referring to page 353 of your Journal, he will perceive what I mean by the *principle of the plan*, which was communicated to me about three years since by an esteemed professional friend, but who at the time did not inform me that it was his own conception; and which I was not aware of until I applied to him, since reading "An Old Surveyor's" letter, to know in what manner he became acquainted with the process. Subjoined is the reply, but at his request his name is withheld; but for your correspondent's satisfaction, I send you the letter to take the requisite particulars from. In the autumn of 1837, he observes, "being engaged upon a survey of 12,000 acres, I looked with some degree of concern at the drudgery of computing the quantities. Mr. B. had previously explained to me his mode of ruling parallel lines across the several enclosures, but this method I thought would be troublesome, and be attended with the risk of injuring the maps. The idea then occurred to me of using a thin piece of horn ruled with lines one chain apart. In the interval that elapsed between my sending for, and receiving the horn, I made of tracing paper the machine I described to you, and find it to answer my purpose, used it to the end of my survey in the spring of 1838, since which time it has not seen the light, but is no doubt amongst my old papers."

I think the above particulars must be satisfactory to your correspondent, at least I hope so; and now perhaps I may be excused asking him, who the inventor of the modified instrument at present in use at the Tithe Office, is? for certainly there is great credit due to him, and which I indeed stated in my work, when I called it an "ingenious application of the above system." If an Old Surveyor will favour me with this particular, I shall have much pleasure in mentioning it in the second part of my work shortly to be published.

I remain, Sir, your's very obediently,

PETER BRUFF.

Charlotte Street, Bloomsbury, Nov. 16, 1840.

SIR—An "Old Surveyor" in your last number doubts the remark made by Mr. Bruff, that the *principle* of the New Scaling Instrument had long been in use by some few surveyors.—In reply I beg to observe that I have known many surveyors of the old school who worked on this principle, by means of a long scale and pricker, taking the amount of the chain widths and transferring them into acres, roods and perches by the decimal table; the new instrument has certainly much improved the system, and having the parallel lines on glass paper is a further improvement. The old system was a very defective one, and repudiated by all really practical men. As to the new instrument, after using it in my office for many months, and in various large surveys—I find it unsatisfactory, it is after all (notwithstanding its high recommendation) best adapted for the schoolboy and the tyro.

I am not surprised at its general adoption, for the former approved system of equalising into trapeziums and triangles is very laborious work, if pursued for a length of time successively, but after giving both a fair trial, I must say I find the old system the most expeditious and certainly the most satisfactory. One feels no satisfaction with the instrument without repeating the operation, in repeating, the results will not always be the same, a third or even a fourth operation will frequently be required, each time requiring the whole to be done over again; whereas by allowing two young hands to figure for each scaler, they check one another, and repeating the operation from opposite points, prevents any serious errors by using proper precautions.

Perhaps I have a little feeling with yourselves against "ready reckoners," but I have experience on my side, and I have laid the *instrument* on the shelf.

It is a pity to see practical men recommending such games of marbles as your Dublin correspondent, if he would work with *eleven* arrows and make *frequent* use of his pen, he would bequeath his marbles to his children. Every *surveyor* should follow his own chain in long lines, and stopping to book his changes, stations, crossings, &c., will find him plenty to do, without carrying a marble bag.

The number of mushroom surveyors whom the pressure of business have hatched into life, has detracted much from the respectability of the profession, the public however are beginning to find out, that old and tried hands are most to be depended on; an engineer too may be a good surveyor in theory, but he will never come up in the field to an old fashioned surveyor. I do not know any thing that would give me greater pleasure than to give a certain eminent gentleman in that line, (well known to our profession, for his upright, impartial, and gentlemanly demeanour), one week's *practical surveying*, he would find there was but little "Sham Abraham" in it.

I shall conclude these few remarks by again assuming a name under which I have before entered your columns,

As your very obedient servant,

"SURVEYOR."

Ashford, Nov. 14, 1840.

ON REMOVAL OF EARTH-WORK FOR EMBANKMENTS.

SIR—In your Number 38, for November 1840, at page 392, you state that "up to April 1837, not even 200,000 cube yards had been teamed to embankment on one face, in one year."

Between Nov. 2, 1839 and Oct. 17, 1840, there were tipped, according to my official returns, on the Birmingham and Gloucester Railway, on one face of embankment, across the valley of the river Rea, near Birmingham, 293,246 cube yards; the mean lead being $1\frac{3}{4}$ miles, and the extreme height of embankment 62 feet from the meadows. I believe that a ratio of progress fully equal to the above, was maintained not far from Gloucester on the same railway, for a few months in the Autumn of 1839; but as the work was then in the hands of the Cheltenham and Great Western Company, I cannot give you farther particulars. I am under the belief that other engineers could supply you with information as to larger quantities than the above being tipped in the same space of time.

I am, your's faithfully,

W. S. MOORSOM, *Engineer.*

[Communications similar to the above are of great importance to the profession; we hope other engineers will follow Mr. Moorsom's example, and favour us with the result of their observations.—ED.]

THE NAPOLEON MONUMENT.

MR. EDITOR—Having in the September number of your highly interesting periodical, perused an article under this head, and feeling a deep interest in the subject, I take the liberty of sending you my own opinion; though, whether it is likely to effect any good, or is worthy of insertion in your Journal, your able judgment will best decide.—During a recent visit to Paris, I was particularly struck by the exhibition (mentioned in the above number) of a full size model of the intended testimonial to the Emperor in the Dôme des Invalides, as not being altogether consistent with that good taste so frequently displayed in the French capital. To every one who has seen the effect of the Baldachino in St. Peter's, at Rome, which is universally acknowledged a complete eye-sore, this striking similarity of arrangement must evidently tend to give the same result. The magnificent Dôme, being itself such a tastefully decorated room, can, according to my ideas, by no means suffer any erection, like this complicated, by an equestrian statue crowned monument, to dispute its grand simplicity. A colossal statue of the hero, say from 18 to 24 feet high, *cast in white metal and frosted*, erected on a circular pedestal of Egyptian porphyry, in the centre of the large Mosaic star, would methinks produce a different effect. The sublime grandeur of the Egyptian colossi, all rude and mutilated as they are, speak for themselves, and in behalf of my opinion. They likewise convince me that supernatural size would here especially answer the purpose. I suggested my idea on the spot to a friend present, and have since found no reason to make any alteration.

Your's most respectfully,

C. TOTTIE.

14, *University Street, Nov.* 9, 1840.

COMPETITION DESIGNS.

K. P. S. IN REPLY TO MR. SPARKE.

SIR—It gives me much pleasure to see in your number for the present month, that you have other correspondents who interest themselves in the subject of competition, and it is with especial satisfaction that I have read the answer of Mr. Sparke, to my letter on the subject of the Bury affair, since it leaves every essential fact in my statement unshaken, except one. Nobody can be imposed upon for one moment by the mist of words in which the Hon. Sec. flatters himself he has enveloped the truth.

It seems I have been misinformed as to the amount of the contract, which is £3,353 instead of £3,550. What then? Does the amount affect the moral principle?

There certainly are cases which differ from competitions, inasmuch as the law is apt to take cognizance of them, in which the proper name by which the transaction is called, varies according to the pecuniary amount involved in it, but as we cannot suppose the Hon. Sec. to the subscribers means to insinuate any analogy, we must conclude that he argues like the damsel who excused her peccadillo because it was "*a very little one.*"

As to the conundrum about the duties, it is too shallow to be respectable. The contract is £3,353,—there is £230 to be laid out in foundations, which it was evident must be laid out to all but those determined not to see, and then there is the painting and plastering. £350, supposing it to be so much, will not cover an excess of upwards of £600.

Though quite unnecessary for the argument, I will beg your readers to peruse the clause referred to by Mr. Sparke relative to the duties. Will any one undertake to say whether it is intended to mean that the duties are or are not to be considered in the estimate. It is most ingenious, and well calculated to maintain a quibble upon. Where the meaning is obscure, we must enlighten it by the context. "*If the subscribers shall be unable to find a respectable builder willing to execute the design of any architect for the sum of £3,000, such architect shall have no claim of any kind upon the subscribers,*" &c. This at least is plain English, and I shall take the liberty to believe it can have but one meaning, even though it should be explained away as satisfactorily as Lord Peter proved his shoulder-knot to mean neither more nor less than a broomstick,* or as Mr. Sparke has explained away all the rest of my statement.

But one word more—I will not dispute whether the contrivers of this business were *called* a committee, but it is notorious to all Bury that it was managed by a *clique* who, according to Mr. Sparke's showing, turn out to have been as irresponsible as they were officious. I could name an occasion on which one of the leading members expressed himself in no measured terms, upon some symptoms of dissent from his authority, shown by other parties concerned.

Enough of this, and more than enough for any good it is likely to produce. I have said before, and say again, that reform must come from the profession, and to them I would recommend a very simple plan, by which it may be effected, viz., that every one should reform himself. In the mean time, Sir, accept another contribution to the *facts*, which I hope to see accumulated, until architects shall be ashamed to rake in the filthy puddle of competition at the command of every body and any body. For reasons which will instantly be appreciated, I omit all names.

It is now nearly two years since the following advertisement appeared in the public papers:—

"To Architects.—Any architect desirous of competing for the proposed enlargement of W—— church, must send in his plans, specifications, and estimates, free of all charge or expence, to the Secretary, the Rev. Mr. T——, Vicarage W——, on or before the 19th January, 1839. For farther information apply to the Secretary."

Application having been made for farther particulars, the following were furnished in reply:—

* See the Tale of a Tub.

"That the committee would require a plan of the different floors of the church, showing the present arrangements and proposed alterations, an elevation of each front affected by the proposed alterations, a longitudinal and transverse section showing the timbers of the roof, &c., together with a detailed specification of the works, and estimate of rendering the church, both inside and out, fit in every respect for public worship. An additional estimate of what would be the expence of repewing the present church on a better plan, in conformity with the proposed new addition. An estimate of the expence for an additional gallery.

"That the limited amount of the funds would not allow of any premiums being given for the plans.

"That the committee considered it indispensable for the competitors to inspect the church.

"That a commission of five per cent. on the sum expended would be allowed to the architect for his plans, &c., including the superintendance of the works."

And now, gentlemen of the profession, what do you suppose was to be the amount of this commission for the *chance* of which all this was to be done, and a journey to be made to W—— at the candidate's expence?

"That the Secretary informs the several architects that the sum to be expended will *not exceed four hundred and fifty pounds!!!*" I write it at length that no one may suppose a figure has been dropped.

The following letter, part of the correspondence, is too curious not to be given entire. The *naïve* impudence of the latter part will not easily be surpassed:—

"*W——, January* 5, 1839.

"SIR—In answer to your's of this morning, I beg to state that the committee desire me to say that they consider a personal inspection of the church necessary. Should you consider this worth your while, I shall be happy to give you any information in my power on the subject. I should state that the length of the church is 60 feet by 16 feet 10 inches, so that the work will be on a small scale. The amount to be expended will not exceed £450. *The Rector of the parish is an Architect, but has not informed me whether he intends to compete for the work.*

"I am, Sir, your obedient servant,

"H—— S——."

Begging every architect who values the respectability of his profession to lend his aid in exposing these scandalous practices.

I remain, Sir, your obedient servant,

K. P. S.

Nov. 13, 1840.

ATMOSPHERIC RAILWAY.

IN our last monthly number we published a letter received from Mr. Pinkus, commenting on an article in our July number on the atmospheric railway, in which he complains that great injustice had been done him, by giving credit to Mr. Medhurst "for having originated the idea of employing the power of the atmosphere against a vacuum created in an extended pipe laid between the rails, and communicating the power thus obtained to propel carriages moving on a road," and to Messrs. Clegg & Samuda "for having rendered this idea practicable and useful, by their simple and ingenious invention of constructing and closing a continuous valve, by hermetically sealing it up with a composition each time the train passes."

In treating on scientific inventions of interest, this Journal pursues the undeviating course of giving the fullest and clearest information, preserving the strictest impartiality as to the inventors; conferring praise where it is justly due, and pointing out error where we consider it to exist. Mr. Pinkus, after denying *in toto* all we have said of Medhurst and of himself, describes himself as "an humble labourer in the field of science," who would "never be guilty of that meanness of mind that would detract from another the merit justly due to him for any mental production." This principle we admire, and cannot but regret that he should have lost sight of it in the very next paragraph of his letter, where he attempts to deprive Medhurst of the praise we awarded him, by describing Papin as the author "of employing the power of the atmosphere against a vacuum." We are aware that this is due to Papin, but if Mr. Pinkus had not stopped short, but quoted our whole sentence, Medhurst must have come in for the praise we justly awarded him, viz. "of using the power of the atmosphere against a vacuum created in a pipe laid between the rails, and communicating the power thus obtained to propel carriages on roads,"—a very different thing from simply "using the power of the atmosphere against a vacuum," which we were fully aware originated with Papin, had been followed by Lewis in 1817, and Vallence in 1824. Returning, then, to the original idea of employing atmospheric pressure against a vacuum inside a pipe, and communicating that power to carriages moving on a road outside it"; we see nothing to alter our assertion that it is the invention of Medhurst, who published a detailed account of the means he employed, in 1837.*

Indeed, however reluctant Mr. Pinkus may be to admit this fact, the following extracts from Medhurst's pamphlet, places the matter beyond all doubt.

In page 15, this passage occurs—

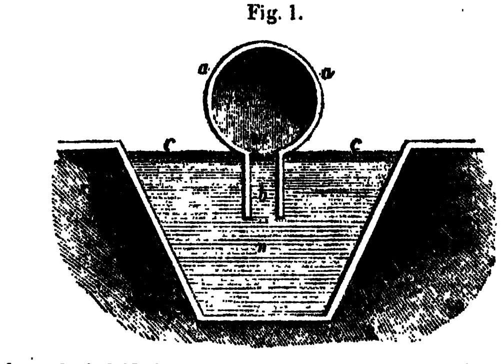
When the carriage is to go through the canal, from the engine, the air must be forced into the canal behind it; but, when it is to go the contrary way, the same engine is to draw the air out of the canal, and rarify the air before the carriage, that the atmospheric air may press into the canal behind the carriage, and drive it the contrary way.

In the following page 16, he says—

It is practicable, upon the same principle, to form a tube so as to leave a continual communication between the inside and the outside of it, without suffering any part of the impelling air to escape; and, by this means, to impel a carriage along upon an iron road, in the open air, with equal velocity, and, in a great degree, possessing the same advantages as in passing withinside of the tube, with the additional satisfaction to passengers of being unconfined, and in view of the country.

If a round iron tube, 24 inches in diameter, be made, with an opening of 2 inches wide in the circumference, and a flanch 6 or 8 inches deep on each side of the opening, it will leave a channel between the flanches, and an opening into the tube. If the flanches of this tube are immersed in water up to the circumference, as represented in fig. 1, where *a*, *a*, is a section of the tube; *b*, the channel; and *c*, *c*, the surface of the water.

Fig. 1.



If such a tube is laid all along upon the ground, with the iron channel immersed in a channel of water, up to *m*, and a piston or box made to fit it loosely, and pass through it upon wheels or rollers, this box, driven through the tube by the air forced into it, may give motion to a carriage without, by a communication through the channel and the water.

Again in page 20, he describes

A plan to combine the two modes together, that the goods may be conveyed within the canal, and a communication made from the inside to the outside of it, so that a carriage may be impelled in the open air, to carry passengers, would be an improvement desirable and practicable. It must be effected without the aid of water, that it may rise and fall as the land lies; and it must give a continual impulse to the outside carriage, without suffering the impelling air to escape.

And aware that his only difficulty was in constructing a means of confining the power in the tube by using a valve in lieu of the water joint, he remarks, that

For this purpose, there must be some machinery which will diminish the simplicity, make it more expensive, and more liable to be disordered, unless executed in the most substantial and perfect manner; but, by skill, by experience, and sound workmanship, it may be accomplished in various ways, one of which I will describe, which, I presume, will evince the practicability of it.

In order to make this in the best manner, the top of the canal should be made of wrought iron (or copper) plates, rivetted together, and rivetted all along, on one side, to a cast iron rail securely laid upon the top of one of the side walls; and made to shut down close, and air-tight, upon a cast iron rail laid firmly down upon the other side wall.

In order to make the plate shut down air-tight upon the cast iron rail, without being rivetted to it, there should be a groove all along, upon the top and inner edge of the cast iron rail, and a thin edge of iron rivetted to the plates all along, to fall into the groove; then, if the groove is partially filled with some soft and yielding substance, as cork, wood, leather, hemp, &c., the thin iron edge will bed itself into it, and shut so close that the air will not escape, with so light a pressure as one pound per square inch.

The plate that is to form the top of the canal, being thus prepared, may be

* This work was entitled "A New System of Inland Conveyance."

lifted up out of the groove two or three inches high, in any particular place of the side that is not rivetted; and, when let down again, the edge will fall into the groove, by the spring and weight of the plate, and stop close as before.

Therefore, if there is a large and light iron wheel fixed in the front of the interior carriage, and close to the side wall on which the plate shuts into the groove; and if this wheel is planted to stand two inches higher than the under side of the covering plate, this wheel, as it passes along, will constantly lift up the plates, and make an opening of two inches wide, or more, and 8 or 10 feet long; and, when the wheel has passed, the plate will fall down into the groove, and close the joint, as before.

Through this opening, a bar of iron may pass, that is fixed to the interior carriage, may project over the side wall, and the outer end may be attached to the exterior carriage by a chain or strap, and pull it along upon its own wheels and wheel track, which should lie along by the side of the wall of the canal.

The iron bar will not touch any thing as it passes through the opening, for the iron covering may be lifted up two or three inches high; but the bar need not be more than one inch in thickness.

In page 24, he says—

The same principle, and the same form, may be advantageously applied to convey goods and passengers in the open air, upon a common road, at the same rate of a mile in a minute, or sixty miles per hour; and without any obstruction, except, at times, contrary winds, which may retard its progress, and heavy snow, which may obstruct it.

If a square iron tube be formed, 2 feet on each side, 4 feet in area, with three sides, and one-half of the top, of cast iron, the other half of the top made of plate iron or copper, to lift up and shut down in a groove in the cast iron semi-top plate, as before described; and if a strong and light box or frame be made to run upon wheels, within the tube, and an iron arm made to pass out, through the opening made by lifting up the plate, as before described, this arm may give motion to a carriage in the open air, and upon the common road, without any rail-way, if the pressure within the tube is made strong enough for the purpose.

The opening of the iron plate should be made in the middle of the top, so that the iron arm may pass out, and stand upright a few inches above the top, to which the strap should be attached, to communicate motion to the carriage.

The frame or box, within the tube, should be 10 or 12 feet long, and must be guided by wheels, on all sides, as large as can be admitted, and as truly formed and planted as possible; the number will be 14 or 16.

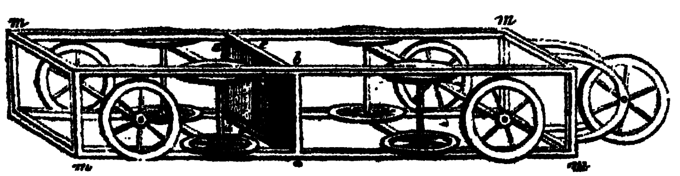
A piston, or vane, must be formed near the middle of the frame, to intercept the air, and must be leathered all round, so as lightly or barely to touch the sides of the tube.

The inside, or middle of this vane, should be open, and the opening filled up and closed by a valve, suspended by an axis across the middle of the opening, so that this valve, by turning on its axis, may open the vane, and suffer the air to pass through, and prevent its impulse upon the vane and carriage, or, by closing the valve, intercept the air, and give it motion.

By this means, the conductor of the carriage may restrain and limit the velocity, and stop the carriage, at any time and at any place, by a communication from the valve, through the opening, to the conductor on the outside; and this will be done without the least violence, shock, or chance of disordering any thing, either within or without.

Fig. 2 represents the vane within its frame *m, m, m, m*; the outside edge

Fig. 2.



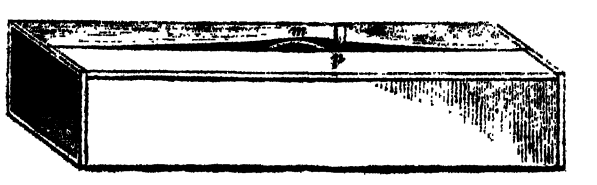


Fig. 4.

of the vane, *a, b, c, d*, is leathered all round, and the middle part, *o, p, q, r*, is open, and is to be closed by the double valve, that is to turn upon its vertical axis *e, e*. The valve will shut, half on one side of the vane *a, b, c, d*, and half on the other; when it is shut, the air will be intercepted, and the impulse of the air will be given to the carriage; but, when the valve is turned a quarter of a circle, it presents its edge to the air, and leaves the interior of the vane open for the air to pass by unobstructed, when the carriage will gradually be stopped, by the friction of the road and the resistance of the outward air. It may be put in motion again, as soon and as gradually, by closing the valve.

m, m, m, m, is the box, or open frame, that is to pass through the tube, on the wheels *n, n, n, n, n*, to support the vane, and the iron arm, and to be impelled by the air in the tube.

Fig. 3.

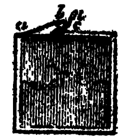

Fig. 3 is a section of the iron tube, with the wrought iron semi-top, *a, b*, rivetted to the flanch, and represented as lifted up by the projection of the wheel under it; and of the crooked iron arm *n*, as it is to come out through the opening, and stand up for the carriage to be attached to it.

The semi-top of cast-iron, *o, p*, is to be screwed upon the tube by the flanch *p*, and, at the edge *o*, is a small projection, which the edge of the wrought iron is to cover, to prevent the rain or dust from entering into the tube.

Fig. 4 represents a part of the tube, with the semi-top as lifted up at *m*, and the section of the crooked iron arm, *n*, as it is to pass out of the opening, besides the wheel that lifts it.

The iron tube should lie in the ground, with the top of it a few inches above the surface; and the carriage should run over it, with the wheels on each side; then the iron arm *n*, would draw the carriage in the fairest position.

The opening being, in this plan, made in the middle of the top of the tube, instead of the side, the lifting wheel will act either way, without being removed; but the iron arm that passes through the opening (to draw the carriage), as well as the arm that is to pass through (to open and shut the valve), must be changed to the other side, when the motion is changed to a contrary direction.

If the carriage is attached to the regulating arm that is to pass through the opening, and that arm is supported by the main bar, the effect will be, that, if by any accident the chain should let go its hold of the arm, the inside valve would instantly fly open; and the vane, being no longer impelled, would soon stop of itself, and the chain might be replaced.

In summing up this invention he remarks,

Although the perfection of this work is not to be obtained but by time, skill, experience, and the wealth of a nation, yet, upon a smaller scale, and less rapidity, the expense will be moderate, and within reach; and the value of it, compared with the present mode of conveyance, would be abundantly advantageous and desirable.

Here then is a clear and full explanation of a mechanical arrangement for employing the power of the atmosphere against a vacuum inside a tube, and communicating the power so obtained to carriages moving on a road on the outside.

No impartial person, and not even Mr. Pinkus can read these passages without being convinced that this most ingenious, though unfortunate inventor Medhurst, had brought the atmospheric system to the point where it was taken up by Messrs. Clegg and Samuda, and that his great practical failure was, that he could not, and did not make the valve air-tight, upon doing which the entire success of the system depended.

And now that we have shown what Medhurst did, and what he failed in, viz., "in making a continuous communication from the inside of the pipe to the carriage tight enough to allow a useful degree of rarifaction to be produced;" we will examine what progress the invention has made since then.

On the 3rd January, 1839, Clegg and Samuda obtained a patent "for a new improvement in valves and the combination of them with machinery." This valve, says the inventor, "works in a hinge of leather, (or other flexible material which is practically air-tight), similar to the valves commonly used in air-pumps. The extremity or edge of these valves is caused to fall into a trough containing a composition of beeswax and tallow, or beeswax and oil, or any substance or composition of substances which is solid at the temperature of the atmosphere, and becomes fluid when heated a few degrees above it; after the valve is closed, and its extremity is laying in the trough, the tallow is heated sufficiently to seal up or cement together, the fracture round the edge or edges of the valve which the previous opening of it had caused, and the heat being removed the tallow again becomes hard and forms an air-tight joint or cement between the extremity of the valve and the trough. When it is requisite to open the valve, it is done by lifting it out of the tallow with or without the application of heat, and the before named process of sealing it or rendering it air-tight is repeated every time it is closed.

The inventor then goes on to describe how, by means of this valve in combination with a line of partially exhausted tubes, it may be rendered useful to move weights on railways. The combination employed being described precisely similar to that invented and published by Medhurst. The only claim set up in the patent being "the method of constructing and using valves as above described." The success of this valve has been demonstrated by six months experience on the Thames Junction Railway, and as the whole combination there employed, *except the valve and mode of sealing it*, is precisely that invent-

ed and published by Medhurst,—it follows that to Clegg and Samuda is due the credit of perfecting what he began.

Now let us see what Mr. Pinkus has done. His first patent we find is dated 1st March, 1834, in this he sets forward a combination precisely similar to that published by Medhurst seven years previously, only proposing to use a rope for his continuous valve, which he terms a valvular cord, and which he describes thus: "A flexible cord E lies in the groove at the top of the cylinder, for the purpose of closing the longitudinal aperture; this cord is to be of the same length as the pneumatic railway, and to fit tightly into the groove or channel. The cord is passed under the wheel c, and over the wheel P; and its purpose being to close the opening in the cylinder, it is required to yield freely when acted upon by the apparatus, and it should be made heavy, and it may be pressed down into the groove by the wheel W, which passes over it."

Now if Mr. Pinkus can prove any better result to arise from this rope than from the valves suggested by Medhurst, he has a perfect right to it. We fear, however, that the success he says, attended his experiments made in 1835 on a model, could not have been very flattering, as we find he took out another patent in 1836, "For improvements in inland transit," in which he says, "the method of carrying it into practice consists in a method or in methods of constructing the pneumatic valve and the valvular cord, and in the manner of using the same, one of which methods hereinafter described, I design *to substitute for and in lieu of the valve and cord described in the specification of my said former patent.*" He then goes on to describe a valve formed of iron plates secured to felt to lay against pieces of wood, which he proposes to fix to the inner sides of the trough, as presenting a smoother surface than cast iron. He next describes a spring copper valve fastened at its foot to the pipe, and meeting at the top in the shape of an inverted V; and lastly, a combination of the two, viz., using half the spring copper valve against the upraised side of the trough, and pressing it against its surface with the valve with iron plates, as before described, which in this case acts as a wedge pressing against the side.

These valves, however, could not have pleased him much better, for on 3rd August, 1839, he obtained a third patent, in which he not only describes a valve similar in every respect to that of Messrs. Clegg and Samuda, but also proposes to seal it with a composition to be rendered fluid and solid, as described by them; with the sole exception of using a galvanic wire instead of a heater to melt the cement. As this patent was enrolled eight months *after* the publication of Clegg and Samuda's specification, we cannot but think that their invention was instrumental in leading Mr. Pinkus' ideas to this valve, as nothing of the sort is discoverable in either of his previous patents.

[Erratum.—For 1837 read 1827, p. 407, 2nd col., 4 lines from the top.]

REFORM CLUB-HOUSE.

(With 2 Engravings, Plates XVIII. & XIX.)

FULLY to describe and explain the interior of the structure would require a plan of every floor—amounting altogether to six, besides as many sections, to say nothing of particular sections on a larger scale, of some of the rooms, perspective views, and drawings of ceilings and other details: in short it would demand a volume similar to that on the Travellers' Club House.* Of course we cannot devote so many engravings to a single edifice, though it be one so deserving of attentive study as this of Mr. Barry's; nevertheless a sufficiently clear idea of the general arrangement, of the sizes of the rooms, and of the height of the different stories, may be obtained from the ground floor plan and section through the building from East to West. Being confined to a single section, we have judged this last to be the best for our purpose, because although one through the centre from north to south, would have shown the ascent from the vestibule to the hall, and the coffee-room and drawing-room above it, it would have shown merely the end elevations of those apartments, not their longitudinal ones—which are their more important ones; whereas the line of section chosen makes no difference as regards the hall, while it explains the character of the staircase, and the room over it, and also shows the kitchen court, at the east end of the building. When, however, we say none, we mean that it makes no other difference in respect to the hall itself than what is evident from the ground plan, namely, that in this direction the three intercolumns are of equal width, whereas the east and west sides being somewhat shorter, the lateral intercolumns are narrower than the centre one, on which account those elevations are better than the others, where the columns are wider apart than is altogether consistent with the richness of character here observable in other respects. This excess of width in the intercolumns is not so apparent in our drawing, because that being both a geometrical and outline one, it is the plan which chiefly explains that the arches between the columns belong to a different plane, viz., that of the wall within the colonnades. Hence it is likely enough that from the first glance at the section it will be supposed that, instead of being insulated the columns are attached to the piers of the arches, in which case the intervals between them would not be too great. It becomes a question, therefore, whether it would not have been better, to enclose the lower part at least of this saloon by open arcades so decorated, whereby a character of solidity would have been there produced, that would have served to relieve and set off the upper colonnades. Still wherefore that idea—supposing it to have presented itself—was not adopted is sufficiently apparent from the plan being neither a perfect square, so as to allow three arches of equal width, on each of its sides; nor so much greater than a square as to afford five spaces—whether arches or intercolumns, on each of the longer sides. Perhaps as the deficiency in the breadth from north to south, could not be supplied without intrenching too much upon other parts, it might have been adviseable to have got rid of the excess in the other direction, curtailing—not the entire hall, but merely the cetral space within the columns, reducing that to a perfect square. By this means, indeed, the breadth of the east and west colonnades would have been somewhat increased, yet that objection might have been got over by apparently contracting the width, putting columns against the wall, corresponding with those in front, and so as to render the distance between them equal to the breadth within the north and south colonnades. This adjustment of the plan, reducing the centre to a square of 28 feet, instead of 34 × 28,—might have rendered some other modifications requisite, and among the rest, some abatement of the present height.

If we have thus far taken the liberty of objecting to what we regard as a rather offensive irregularity as regards the colonnades, we commend the mode of grouping of two columns and square pillar, here employed at the angles, which produces a very desirable fulness of effect, as well as appearance of solidity at those points, and at the same time avoids the confusion—and perhaps heaviness withal—that might have resulted from three columns similarly placed. Another pleasing and, we believe, original circumstance is, that in the upper and lower colonnade on the south side, a view is admitted into the coffee-room and drawing-room over it through the centre arcade, which is to be filled in with plate glass to within a few feet of the floor, that is, to the level of the chimney-piece. By this means, the saloon itself will always present a striking architectural scene as so viewed from either of the two principal apartments, especially of an evening when brilliantly lit up. The mode also of lighting the saloon entirely through the cove, appears to us both a novel and happy one, although we can at present merely guess at its effect, it being quite blocked up with scaffolding when we last went over the interior of the building, when very little progress had been made in the decorations, or rather, they were hardly commenced at all, nor was it began to be paved. The staircase was also then a mere shell, with brick walls, and without any steps. Consequently, until we can see the interior again, in a much more advanced, if not perfectly finished state, we can add very little to the information the plan and section supply as to the parts just mentioned. For which reason, we must be allowed to reserve further description for another opportunity, and request our readers to consider the present account merely a provisional one.

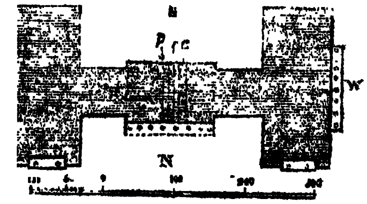
* The whole of the plates in that work have lately been pirated in the most barefaced manner by the editor of the Revue Generale d'Architecture, without the slightest acknowledgement, or mention of the source whence they have been taken, notwithstanding that a copy of the publication was actually given to the French editor in order that he might give a notice of the book! Yet instead of doing any thing of the kind, he does not even inform his readers that there is such a volume in existence, but makes it appear that both his article and the plates are entirely his own, and the information collected by himself while he was in London. It is true the drawings are not exactly facsimiles, for they are considerably reduced in scale from the originals, and in other respects far less satisfactory: still that circumstance does not cancel the act of piracy, or the injury done by it to the English publisher.

Ryde, Nov. 7.—The committee appointed to decide on the plans for our new church, have selected the designs of Mr. T. Hellyer, architect It is a handsome structure, and the interior is composed after the model of the Temple church in London. The subscriptions for the building are progressing steadily, and the contributions for enclosing the new burial-ground already amount to more than 150*l*. Too much praise cannot be given to our vicar, the Rev. W. S. Phillips, for the energy and exertions he has put forth to accomplish these two important objects.—*Hampshire Advertiser.*

ARCHITECTURE OF LIVERPOOL.

Sir—When I first saw the remarks of your correspondent "Eder" in a Liverpool paper, I felt strongly disposed to make a few observations in reply to some of them, which seemed to me strangely at variance with his professions of careful and long continued architectural study. This inclination was confirmed when I found they had obtained a place in your journal, and would thus fall under the notice of so many interested in the matters they refer to. In putting this design in practice, I shall borrow his introductory paragraph, in so far as it relates to partiality and prejudice, both which feelings so inimical to all fair discussion, I can most candidly disavow.

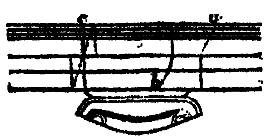
The Custom House is the first building noticed by Eder—its size perhaps entitles it to such priority. He applies the terms "imposing and magnificent," to this structure. Now any very large mass of building may be allowed to be *imposing*, if of an adequate height, but magnificence implies something more than mere mass of material and extension of surface: it includes, I conceive, a symmetrical arrangement of parts, fine proportions, and a degree and character of ornament suited to the importance and purpose of the building. In these three points I hold the Liverpool Custom House to be most lamentably deficient. First, as to *arrangement* or *composition*. The building is on a plan much like the letter H, the cupola occupying the centre of the cross part of the letter, and a portico on one side of the cross, and on each of the upright parts. The consequences of this arrangement are destructive of all fine perspective effect, for when viewed on its north front, the cupola serves only to destroy the effect (such as it is) of the portico on that side, and seen from the east and west fronts that feature seems hardly to be part of the pile, so completely is its connection with those fronts hidden by the projection of the wings. This cupola (in his opinion, in which every body I imagine must agree with your correspondent), in fact never terminates the perspective from any point of view, nor combines with any of the intersections of the wings and central portion of the mass. With regard to the position of the porticoes, that to the north is buried between the wings, and can never be seen in profile. and its projection is so slight that were it not that the only light it ever receives from the sun falls very much aslant, and consequently gives a great prolongation of shadow, it would have no more relief than a row of attached columns with a pediment over them. The above remarks as to want of projection, apply with greater force to the other two porticoes, which however *can* be seen in profile, or obliquely, though for reasons I shall point out when I come to speak of the *proportions* of the parts, their effect is completely destroyed. The site of this building was well adapted to a cruciform plan, and had such an arrangement been adopted, the porticoes, however deficient in projection and depth, would at least have formed suitable terminations to the several portions of the cross; and the cupola, however foreign to this, so called, Grecian design, would have risen naturally, as I may say, at the intersection, and have terminated the converging perspective of the body and transepts with good results as regards its own effect and importance, and without interfering with the porticoes in those respects. Such a disposition of the plan would also have insured a better distribution of light, and greatly have benefitted the interior arrangements, which as your correspondent justly observes, are sadly wanting in this point. As regards the proportions of the several fronts, and the features which compose them, it seems to me that very little consideration, or consideration to very little purpose has been bestowed on them, more especially as respects those very important parts of the composition, the porticoes. Their projection (for they are all alike) is so slight as to appear nothing in comparison with their frontal extent, and to take away all idea of shelter or shade. I do not know whether Candidus will include expression as one of the banished or obsolete architectural terms, but this quality (for I for one believe in its existence) appears to me to be utterly wanting in three of the fronts. As I wish to advance nothing without endeavouring to give a reason, I shall explain myself as well as I can. I am of opinion, then, that there are two general proportions in which a portico may be combined with a front, of which it does not occupy the whole extent, without loosing its own effect, or interfering injuriously with that of the front of which it forms so material a feature. These proportions seem to me to be firstly, such as shall give to the portico the greater part of the façade, and make the remainder on either side appear as mere adjuncts or accessories thereto; or secondly, such as shall make the portico a subordinate feature in the design, leaving an extended surface on either hand. In the first case the impression on the mind will be (such at least is the effect with myself,) that the front being of a proscribed extent both as to length and height, and a portico a requisite part of the edifice, that portion had been kept within the extreme dimensions of the site for the purpose of preserving to it a fitting proportion as to elevation: and in the second, that the portico being as before supposed a necessary and ornamental feature in the proposed arrangement, had been so proportioned to the whole extent of front as not to destroy its unity and continuity of appearance. The expression of the first named portico, I conceive, will be found that of dignity and grandeur combined with use, and that of the second more allied to comfort and convenience judiciously united with a due regard to ornamental effect. Of the first mentioned proportion I consider the portico of the Fitzwilliam Museum at Cambridge, a good example. As a specimen of the second I may quote that of the India House, inharmonious as that front may be in some of its details. In spite of what I have said above, I still greatly prefer the truly Grecian application of the portico, where it includes the whole front of the building, and continues without interruption or break, save its own angle, the order or entablature, as the case may be, of the lateral portion. But to apply these remarks to the building under consideration.



The east and west porticoes of the Liverpool Custom House occupy, to my eye, exactly the unhappy medium between the proportions I have attempted to describe; and instead of leaving the mind at rest to contemplate and enjoy their air of simple dignity, or of inviting and hospitable shelter, together with the varied effects of light and shade of which these beautiful architectural features are capable when happily conceived and applied, they distract the eye, both mental and physical, by a puzzling uncertainty as to the meaning of the architect, and by their bareness and lack of depth give no idea but that of useless show, and of an exposed, comfortless, and contracted entrance passage. With regard to the north or principal front, the portico has an advantage over those of the east and west fronts—having in rear a slight projection of its own width from the main building; this gives an appearance of greater projection from the general line, but is of no avail as regards the shallow and ineffective aspect arising from deficiency of depth. The proportion which this portico bears to the whole space between the wings is nearly the same as the two already described bear to their respective fronts, and it appears to me to labour under the same uncertainty as to whether it be a principal or accessory in the general design. The wings themselves are perhaps not too far in advance as respects their own proportion as *wings*, but they unquestionably do stand out to such a degree, as to drown completely the portico and its adjoining projection. The fronts of the wings which consist of openings of three intercolumniations divided by two columns in antis, and a flank of about two intercolumns pierced with windows, on each side, are certainly the most effective and least objectionable parts of the front under notice, but I am inclined to think that a greater height of blocking either over the whole front, or at least over the central portion, would tend to improve their aspect. I come now to speak of the rear or south elevation which Eder describes as "infamously miserable,"—terms which well apply to the whole of the wings on that side, but not, I maintain, to the main front which comprises, in my opinion, the only really redeeming feature in the whole building.

All pretension to Grecian character appears here to have been abandoned. The cornice of the columnar order is, to be sure, continued, but without the frieze and architrave, and being of good projection, with a massive dentil member in the bed-mould, it harmonizes well with the general character of this portion of the building, which is most decidedly Italian. Though I think the central projection of this front is, like those in the others, faulty in its indecision of proportion to the whole, still, in itself, I consider it in all respects much the best part of the structure. It consists of a plain well-proportioned elevation, divided into three parts by two slight breaks. The middle portion of the three is pierced below by three open segmental arches leading through the building to the opposite front; and above these, three semicircular-headed windows of good proportions, and pleasing though simple character. The lateral divisions have above each, one window corresponding with those of the centre; and below, a window recessed in an arch similar to those forming the three openings above mentioned. The front is divided horizontally by a bold string course, and surmounted by a massive but suitably proportioned plain attic wall, with its cornice and blocking. The impost moulding of the upper windows is also carried through, which lightens, without too much cutting up, the massive and substantial piers which divide them. There is a good height of plain wall between these windows and the cornice, which, in my opinion is a great assistance towards gaining dignity of aspect, giving me always the same kind of impression as a lofty forehead surmounting a human face. The solid and void are, I think, very happily apportioned in this front, and though I could wish for a better description of rustic work than the horizontal channels in the basement, still the effect of the whole is simple, substantial, and dignified. Here, and here only, does a cupola, supposing it to be something very different from that which really exists, not appear misplaced. The attic wall hides the roof completely, and conveys the idea of a solid support for the mass above it, and the breaks dividing the front are so proportioned as to carry the eye easily upwards to the plinth or stylobate of the cupola, which falls just enough within their line to give the appearance of a proper degree of stability. In the article of decoration, which I mentioned as the third requisite to fill up my idea of magnificence, the Liverpool Custom House offers but little for our consideration, and the quality of what exists can hardly, I imagine, excite a wish that there was more of it. It is difficult to conceive that Greek details could be applied with a more complete absence of all classical effect and feeling. Unfluted Ionic columns, with fluted tori in their bases, composed each of eleven stones; pilasters with capitals, whose mouldings are certainly copied from Greek examples, and enriched, according to established use, with water-leaf, &c., but which mouldings, alas, project more than three times as far beyond the faces of the pilasters, as the pilasters do from the wall, the projection of these latter being barely 3¼ inches to a diameter of 4 ft. 6 in. The projection of the entablature follows, of course, that of the pilasters, and shares in their meagre aspect. In the architraves of the porticoes it appears that stone could not be obtained in sufficient lengths to bear from column to column, and the architect has had recourse to the method of notching shown in Fig. 2.

Fig. 2.



Plan of joint at C.

The effect of this mode of jointing is, that in one portico the part marked *a* has broken through and the stone fallen considerably out of the horizontal, a defect which is only too clearly shown by the broken lines of the tenia moulding and the faces of the architrave; and in another a fracture has occurred as shown at *b*, but not to the same extent. Might not these evils have been avoided by showing a vertical joint in front, and backjointing the stones as shown by the dotted lines at *c*. This must be considered a digression as it belongs rather to the constructive part of the matter; but it was mentioned for the purpose of calling attention to the bad practical effect, of a mode of construction which is in itself an eyesore, and which is enhanced in the present case by the fact, that the stones resting on the columns are almost uniformly some degrees darker in colour, than the intermediate ones which are notched into them. Through some defect, as I imagine, in the foundation, a very serious fracture is visible in the N. W. wing over one of the windows within the recess. But to return to the details; the stylobate so much commended by Eder is a plain square plinth, projecting just sufficiently to receive the bases of the very slab-like pilasters I have described, whose moulding is also, as noticed by your correspondent, carried entirely round the building, with the exception of the south front and wings. This stylobate is certainly much too low to be in proportion to the order—as to the doors and windows, I marvel much what any one can find to admire in them. The windows, except those I have mentioned in the south front, and similar ones under the north portico, are either plain oblong holes, or have a meagre ghost-like architrave, without even the knees or projections at the upper angles to be found in the only genuine Grecian example of such features in the Erectheum. The doors *may* be copied from Greek examples; but who can say that the upright unenriched cyma, is not an ungraceful member? I imagine that the very vertical profile of these mouldings, was adopted in the originals for the better display of the ornamental surface, which decorated them; but as here applied, in their naked state, they are positively ugly. The trusses of the doorways are, to my eye, little less unpleasing, and the nature of the stone and quality of workmanship, give no great effect to what ornaments they can boast. I have as yet said nothing of the interior, or of the details of the cupola. The whole of the former is not yet opened to the public, the fittings of the long room being incomplete. Having had a view of this room, I can only say that it seems to me no great improvement on the exterior. The plan is confused and choked, and the effect of space destroyed by the numerous columns, which, in their disposition, evince a singular disregard to any regular arrangement. The internal cupola, which springs from pendentives rising upon the entablature of the Ionic order of this room, is spacious, and considerably enriched, but claims no notice on any other grounds. On its exterior companion I must decline making any remarks, as my disclaimer of prejudice might perhaps not avail me, were I to say all I think of it. I believe, however, the original design of the architect was not so utterly tasteless. That part of the interior already occupied is sufficiently and fairly described by Eder, being very dark and inconvenient. I have trespassed long on your valuable space; my excuses are that a great deal of unmeaning, and I think ignorant admiration has been bestowed on this structure, both by residents and visitors; that I have never heard a reason given for any thing which has been said in its favour; that all that is the least good in it seems to have been uniformly overlooked; and that it is one of the most extensive and costly buildings which have been erected in this country of late years, having occupied more than ten years in completion, and having cost, as I have been informed, a sum approaching £400,000. In conclusion, I hope I have said nothing to impugn my opening professions of impartiality. Let those who have seen this building judge for themselves, and if, in comparing these remarks with the original, they consider the objections urged beyond the bounds of just and fair criticism, I hope they will, as I have endeavoured to do, give the reasons which influence their opinions; should such meet my view or that of others who think like me, I hope they will be judged of in the spirit of candour, which I trust has guided my pen in the foregoing observations.

Your's, &c.,
H.

Liverpool, Nov. 9, 1840.

Since the above remarks were written, the Long Room has been completed and opened for business. I have only to add, as regards this room, that, although a vista is preserved through its entire length, the effect is destroyed before one third of that length is traversed, by the confused appearance presented by the columns. This arises from the strange indifference here manifested to regularity of intercolumniation, which is such that, looking on either side of the room, no two pairs (not couples, for there are no really coupled columns, however nearly they approach such an arrangement) of columns seem equally far apart. The coffers of the cupola appear much too shallow, and the mouldings as much too large for the depth of the coffers, though perhaps not so when viewed, with respect to their surface, rather than their depth.

VICTORIA ROOMS, BRISTOL.

Sir—The portico of the Victoria Rooms, Bristol, although correctly placed in the Octastyle Class in the table of porticoes given in the Civil Engineer and Architect's Journal for this month, is therein stated to have five intercolumniations, a contradiction which you may not perhaps think it necessary to explain; allow me, however, to add that there is an important omission in the description of it, as the pediment I am happy to say is sculptured, or more properly is being sculptured, from a working model by Mr. M. L. Watson, the principal relief from the face of the tympanum being 2 feet 3 inches. I shall feel obliged by your attention to this letter.

And remain, Sir, your most obedient servant,

Charles Dyer.

36, *Guilford Street, Nov.* 11, 1840.

ON THE DRAINAGE OF LOW LANDS.

By Mr. William Fairbairn.

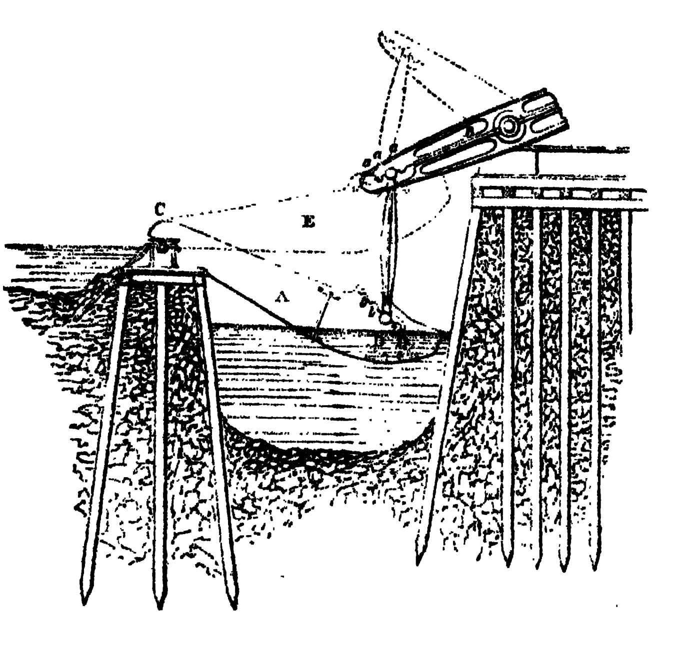
There are few subjects of more importance or more deserving of public attention than the drainage of lands. In cultivating land below the level of the sea, drainage is one of the first steps, for unless the superfluous waters of a low marshy district be freely removed and discharged at a level above its surface, it is in vain to look for productive crops, however rich the soil or the alluvial deposit may be.

Hydraulic machines of almost every description have been in requisition for this object, and in countries, such as Holland and the Fen districts of Lincolnshire, where the land is in many instances several feet below the sea, those machines have been extensively used, and many improvements have from time to time been introduced. Formerly windmills and animal power applied to scoop-wheels seem the only methods adopted, but since the introduction of the steam engine a material change has been effected. Engines of great power may now be seen giving motion to wheels of 25 to 30 feet diameter, discharging large quantities of water from the lower to the higher levels.

The scoop-wheel, although a simple and effective machine, is not (according to Mr. Fairbairn's opinion), the most economical for the drainage of low lands. In countries where fuel is expensive, it is an object of great importance to obtain power at a cheap rate, and by the application of the steam engine upon the Cornish principle, a saving of three times the fuel now consumed may be effected. The consumption of fuel by a well constructed condensing engine is from 10 to 12 lbs. of coal per horse power, per hour, or 10 lbs. of coal will raise 2,000,000 lbs. of water one foot high in a minute; whereas a single acting Cornish engine, according to the returns, will raise with the same quantity of fuel 8,000,000 lbs.—a duty four times greater than has yet been attained by the common condensing engine. Taking it, however, at only three times the duty, or 6,000,000 lbs. one foot high in a minute, the saving is even then so great, as to be entitled to the attention of proprietors whose lands are situated at a level requiring the aid of steam to clear them of water.

From these considerations it appeared to Mr. Fairbairn desirable to apply the Cornish engine, and having been requested by parties interested in the drainage of the Lake of Haarlem, to consider the best and cheapest means for the attainment of that object, he proposed a machine, of which the following is a description.

In raising water by the scoop-wheel, it is obvious that a uniform force is necessary to overcome the resistance upon the floats, as they successively discharge their contents from the lower to the higher level. This resistance being constant, the force applied, and the quantity of fuel consumed, will be equal to the load, or to that of a low pressure condensing engine, similarly constructed to those on board of steam boats. The effect produced on the bailing-scoop will be totally different, and instead of a continuous action as exhibited in the common wheel, a reciprocating motion will be produced, and the same economy insured as is now exemplified in the returns of the Cornish engines. In applying this description of engine it becomes necessary to adopt the reciprocating principle, and by raising a weight suspended at the opposite end of the engine beam B, the large bailing-scoop A, revolving on a fulcrum at C, descends to the lower level, and is filled with water through the opening valves D, D. The weight having been elevated to the full height of the stroke, it descends by the force of gravitation, and raises the bailing-scoop to a horizontal position as at E, causing the water to flow over the pivot C, into the level above. The same process is repeated, each stroke by the admission of steam into the cylinders to raise the weight, and the bailing-scoop is again elevated by its descent.



The principal advantage peculiar to this machine, is its adaptation to the single-acting Cornish engine; first, by the introduction of a portion of high pressure steam to overcome the inertia of the weight; secondly, by its subsequent expansion to maintain the momentum; and lastly, by the gravitation of the weight to lift the load; on the same principle, in fact, as the engine at the East London Water Works, under the direction of Mr. Wicksteed, and as those in Cornwall.

The bailing-scoop is 25 feet long and 30 feet wide, composed of boiler-plates, with two partitions to strengthen the bottom and support the valves for the admission of water at D. The machine is calculated to raise about 17 tons of water each stroke, and with an engine of 60 horse power will effect a duty equal to 2½ or 3 lbs. of coal per horse power, per hour. It will be observed that the length of the stroke continues at all times the same in the cylinder, whilst at *a a*, *b b*, &c. it is varied by a series of stops fixed horizontal to the sides of the engine beams, and upon inclined planes on the bailing-scoop. This is done in order to lessen or increase the dip, and to accommodate the lift to a height commensurate with the difference of the levels which may exist between the surface of the lake and the height to which the water has to be raised.

ON THE COMBUSTION OF COAL.

Sir—Having lately submitted to the public an improved mode of introducing air to the gaseous matter of coal in a furnace, by which its complete combustion is effected, and the generation of smoke necessarily prevented; and finding that the principles on which this is produced have been misrepresented or misunderstood by the contributors to some of the public journals, I am desirous, through the medium of your columns, of being set right in the public view on this important subject. In some instances, indeed, the effect produced by my mode is attributed to causes which are the very reverse of the fact, and though evidently by a friendly hand, yet the result is so opposed to chemical truth, that I am unwilling to sanction such an explanation of the principles on which I have effected perfect combustion on the large scale of the furnace.

In the treatise published by me on the "combustion of coal, chemically considered," I have explained the source of those errors into which the patentees of "smoke burning" systems have fallen, by their search after a high temperature, and looking to that temperature as the means of consuming the gas or smoke, to the utter neglect of all that regards the quantity of air admitted to the furnace, or the conditions on which it combines with the combustible. In that treatise I have mainly relied on the fact that the question of effective combustion is a question as regards the *air*, and not the *temperature*. Modern patents have run on the erroneous idea that the gas evolved from coal in the furnace, and from which flame is exclusively derivable, is to be consumed by bringing it into contact with a mass of highly ignited carbonaceous, or coky matter. This I deny, and consider it to be not only a chemical fallacy, but a great practical error. On this ground, therefore, I am unwilling to be considered as regarding the question of a high temperature as the essential to the ignition or combustion of the gaseous matter of coal. My mode of effecting combustion, by introducing air to the gas in the way of numerous jets, depends for success on principles quite distinct from those which are attributed to the action of heated air. By one writer, the effect of my system is stated to be attributable to the circumstance of the air being heated in the passage through the diffusion tubes; now these tubes are used by me for the sole purpose of throwing the air into small jets, corresponding, in principle, to the jet from a blow pipe. This mode of explaining my principle goes neither to the right cause or effect.

So far from the tubes or pipes, which are made of fire clay or cast iron, heating the air in its passage through them, I have proved, practically, that the combustion goes on equally when the tubes are black and cold, and the air passing through them necessarily cold; this cold air, on issuing from the numerous small orifices, conveying the idea of jets of *flame* rather than *air*. It is important to state that I place no reliance on the question of the temperature of the admitted air.

It has been stated in explanation of the effect produced by my diffusion tubes, that as there is always plenty of air, or oxygen, in the furnace, and a deficiency of heat, the introducing the air at a high temperature, supplies this deficiency. This is directly the reverse of what I have stated to be the condition of the furnace, and the flues leading from it. The following extracts from my tract will put this in a clear point of view.

At page 124, I state, "The leading condition of the combustion of the inflammable gases being the *mixture* with the oxygen of the air in given quantities, and at a given temperature, those inventors have in too many instances, to the utter neglect of the former, exclusively directed their attention to the latter,—the obtaining the highest degree of heat, even to incandescence, for the gases. Now this is unquestionably the condition which demands the least attention on their parts, if *any at all*."

Again, page 129, "It is the palpable oversight of the distinction between increasing the *faculty* of combustion, and actually producing that combustion, which has led to that manifest chemical blunder,—the supposing that coal gas is to be *burned* by the act of bringing it into contact with bodies at a high temperature: or, in the words of the patentees, by 'causing it to pass through, over, or among, a body of hot glowing coals.' In our efforts then, towards effecting the combustion of the gaseous products of coals, it is essential that we steer clear of this hitherto unquestioned practice: attending solely to the question of *air*, and all that has reference to its introduction, distribution, and diffusion: for we may take it for granted, that the condition of *heat* is but a secondary condition; and that the required temperature will never be wanting in the furnace, from the moment we '*light the fire*,' if air be supplied in the proper quantity, at the proper place, and in the proper manner: but if these conditions be not satisfied, an accession of heat cannot remedy the evil, however it may aggravate it."

I assert then, that there can be no greater fallacy, than supposing that giving a high temperature to the air admitted, can be the means of effecting the combustion of the gases, or the prevention of smoke. An analogy has been drawn between the effectiveness of hot air in the manufacture of iron—this however bears no analogy with the introduction of hot air to the furnace, as the means of effecting combustion or preventing smoke. With your permission I propose considering this point on a future occasion—at present I confine myself to denying the assertion that my plan obtains any advantage from the circumstance of the air being heated in its passage into the flues through the small orifices of my diffusion or distribution tubes.

I am, Sir, your's, &c.

C. W. Williams.

Liverpool, Nov. 20, 1840.

THE NELSON MONUMENT.

Sir—Since I last addressed you, the first stone of the Nelson Column has been laid, the work is progressing rapidly, and will continue to do so until the public rise en masse to protest against so great an outrage upon the principles of beauty, or, peradventure, the subscriptions be, as at present, insufficient to complete the structure. We shall then have a piece of a column, to show succeeding generations the lofty standard of beauty amongst us, and to point out how *we* delight to honour the great, the virtuous, and the brave. Shall we, the British nation, permit this living libel to appear against our love of art; glorying in the matchless works of our ancestors, shall *we* allow posterity to point with derision to the evidence of their effect upon us. Enough has been said to show that the Nelson Committee are alone in their project, and it will be disgraceful, if the public submit to have this column thrust upon them, in opposition to their better judgment. Those journals in which we place most confidence in matters of taste, the Athenæum, the Literary Gazette, and the Art Union, have all protested against the proposed column; but despite this and the positive opinion of the Select Committee of the House of Commons, the projectors pursue their object *per fas aut nefas*, and the stone which Wellington would have been proud to lay, is laid, with no public announcement, and no popular enthusiasm, by the Secretary of the Committee. We do not hesitate to say, despite the expression of condemnation upon the whole building, that the *portico* of the National Gallery, exhibits many architectural beauties in its internal columns, and the depth of shadow caused by the projection of the antæ in front of the wall, and it is the portico which the pedestal of the column will completely hide. With all deference to one whose opinion as to the good effect in juxta-position of colossal, and ordinary proportions, demands from all, the highest respect, I would beg to notice that St. Peter's at Rome, has been objected to on account of the enormously disproportionate figures lessening the effect of the architecture, and St. Paul's itself, for the difference in size of its two internal orders. Sir F. Chantrey in his evidence as to the effect of the column as an ornamental object, says, "the Trajan, the Antonine, and the Napoleon columns are the only monumental objects of this class that I have ever looked upon with entire satisfaction; I read the history of the man on the shaft of the column, and the mind is thus reconciled to see the statue so elevated. I may be told we have not money enough for a work of this character, that naval exploits furnish bad materials for sculpture, or that the arts of this country are in too low a state to accomplish so noble a work; then I say, abandon the impossibility at once, and try something more in keeping with our means and our genius." The "general observations by T. L. Donaldson, Esq.," contain opinions as to the bad effect of a naked column. If, therefore, it can be shown, not that the funds do not suffice to enrich the shaft with bas-reliefs, and crown the column with a statue of bronze, but that the subscriptions are actually inadequate to complete the denuded shaft and the perishable statue, and if in addition to these sufficiently cogent reasons it can be proved, that a colossal column, when used without the structure of which it is as much a part as the leg is of the man, is an outrage against our most cherished principles of beauty,—it becomes the people to protest loudly and speedily against the infliction of so great a national indignity.

I am, Sir, your obedient humble servant,

A Lover of the Beautiful.

36, *Tonbridge Place, New Road,*
November 20, 1840.

ON COMPUTING EARTHWORK.

Sir—Observing an article in your October number, page 334, on the methods of computing Earthwork, by Mr. S. Hughes, in which the writer asserts, that the tables of Messrs. Macneil and Bidder, "are useful only for calculating sections where the scale is very small, and where the heights cannot be taken otherwise than in feet—and that where the scale is sufficiently large to show the heights in feet, and decimals of a foot, they are of no use." I take the liberty of transmitting to you the following for the purpose of proving that the tables of Messrs. Macneil and Bidder, are as useful for such calculations, where the heights are in feet and decimals, as in feet only.

I have at present the tables of Mr. Bidder only at hand, although I constantly make use of Mr. Macneil's for similar calculations, but an example based on the tables of the former gentleman will be equally illustrative of the use to be made of those of the latter.

For my purpose I have selected the same example as Mr. Hughes, in page 336.

Example.—Suppose a piece of cutting or embankment 39·8 feet deep at one end, and 24·6 at the other end, the base or top 30 feet and slopes 2 to 1, required the area, which being multiplied by the length, shall give the true content.

	Mid. part.	Slopes.
Intersection of columns 40 and 25, gives	79·5 and	2628.
Ditto ditto 39 and 24, gives	77 and	2471.
Difference	2·5 and	157.

$$\text{Then } \frac{\cdot 8 + \cdot 6}{2} = \cdot 7,\ \cdot 7 \times 2\cdot 5 = 1\cdot 75,\ 1\cdot 75 + 77 = 78\cdot 75 \text{ mid. part,}$$

$$\cdot 7 \times 157 = 109\cdot 9,\ 109\cdot 9 + 2471 = 2580\cdot 9 \text{ slopes.}$$

Mid. part $78\cdot 75 \times 30 = 2362\cdot 50$
Slopes $2580\cdot 9 \times 2 \text{ to } 1 = 5161\cdot 8$

Total contents in yards per chain 7524·3.

$$\text{Then } \frac{7524\cdot 3}{22} \times 9 = 3078\cdot 18 \text{ correct area.}$$

In practice the last operation forms no part of the calculation, as the lengths are taken out in chains and decimal parts.

I remain, Sir, your obedient servant,

Geo. B. W. Jackson.

Radcliffe Terrace, Goswell Road.
Nov. 24, 1840.

[The above is a very round about way for ascertaining quantities, to say the least of it.—Ed.]

RAILWAY MANAGEMENT.

... Before railways can ever be expected to be properly managed, several important alterations must be made in the present system. In the first place, the Directors must effectually suppress the propensity to *amateur engineering* on the part of the "clever practical men" of their body, of whom all boards have more or less. In the next place, they must make a common sacrifice of all patronage and personal consideration in the appointment of persons to situations, when any neglect would be likely to be followed by danger to either life or property. Were this system to be fairly and honestly acted upon, I have no doubt the necessary result would be the appointment of an individual, to whom would be confided the *entire* and *uncontrolled* management of the whole of the *out-door* business of the railway. To him would be committed the whole charge of the selection, employment, pay, and superintendence of every engineman, fireman, guard, porter, rail-layer, and labourer on every part of the line, any of whom he ld fine, punish, or dismiss at his pleasure, and on him, and him ..., should rest the responsibility, both with respect to the public and the Directors, of every hindrance or accident which might occur. In proportion to the success of his management he should be paid, and in his appointment it should be distinctly intimated to him, that in the event of his being found unfit for his office, or even *unfortunate*, no hesitation or delicacy would be observed with respect to his dismissal and the appointment of another in his room. Any person aware of the importance of the duties which would devolve on an officer of this description, would at once perceive that they could not be properly and efficiently fulfilled without his *constantly traversing every part of the line*, and by personal inspection and observation, making himself intimately acquainted with the respective abilities, character, and disposition of every man employed under him, obtaining accurate knowledge of the varying circumstances of the traffic, and of those parts of the railway, where danger was most to be apprehended, and by the foresight which, by this means, he would be enabled to exercise to prevent the confusion and accidents with which the present system is rife. The influence, moreover, which an officer of this description could exercise over the men, would be instantly visible in their guarded and more careful conduct, the well disposed from a hope of reward or promotion, and the bad from the fear of detection and punishment. Energy, perseverance, and tact, combined with sobriety and habits of business, would be the chief requisites in his character. It would also be essential that, in addition to his being an experienced engineer, he should be *practically conversant* with the nature and details of every man's employment, especially that of the engine-men, as a more self-important and uncontrollable set of men do not exist, if they have reason to think that those who are placed over them are not perfect masters of their craft.

The first thing to which I should suppose a person placed in this situation would direct his attention and instantly prohibit, is the very common practice of making use of either line while travelling in the same direction, a practice so obviously fraught with danger, that I am astonished how any board of directors or superintendant can, for a moment, allow it, except under the most extraordinary circumstances, and most stringent and well defined regulations, whereas, on the contrary, there appears to be no instructions whatever on this important point, nor any farther discretion exercised in the practice of it, than such as the circumstances of the case, in the opinion of those present, seem to require. Indeed, throughout the whole system, the absence of *individual* and *responsible* management is glaringly evident, and in all cases of danger and emergency, every one seems to "do that which is right in his own eyes."

Then as regards the signals, there is a red light for danger, a green light which indicates neither "danger or safety," and a white one which it would appear means anything or nothing, as the engine-man can best make out, all of which are confided without check, and almost without instructions, to ignorant, forgetful, and sometimes careless men. Can any reasonable person for a moment expect, that with a complex and ill-defined code of signals like this, railways are likely to be free from danger, or would be not rather express his astonishment, that so *few* accidents should have happened. If the road *is* perfectly clear, what necessity is there for any signal whatever, if it *is not* so, what need of more than one? Instead of all this complexity, I would at once adopt the broad and intelligible principle, that *a signal of any kind, exhibited under any circumstances*, should *always indicate danger*; and in order to carry it out, I would render it imperative on *every train* to have a light in *front* and one *behind* from sunset to sunrise, placed at such a height from the ground that persons moving about could not intercept the view. *Similar lights* should be exhibited during the same period at all the stations, placed at the *same* and occupying the *same relative position*, as those in the trains, so that an engine-man could not be certain, on seeing the signal, that it was not a train in his way. But the improvement to which I should be disposed to attach the most importance, and from which I should anticipate the happiest results, would be to place the whole of the station signals on a machine, which should be so far self-acting as *always, when left to itself, to indicate danger*, and to *require an effort* on the part of the attendant, before that warning could be removed; from this very simple precaution would be derived the important result, that *neglect of* or *inattention to* the signals would *insure safety*, which is sufficiently evident, as, whether danger did or did not ... the signals would always indicate it, and cause the coming train to stop until it should be removed. There are many more points connected with railway management, which are by no means brought to the greatest degree of perfection of which they are capable, but for the present, I will leave them for a future communication, should it be necessary.

I am, Sir,
Your's very respectfully,
A Railway ...

November 24, 1840.

REVIEWS.

... *on Iron and Steel.* By David Mushet.

(THIRD NOTICE.)

Continuing our remarks upon the subject of iron, we may remark that the ores from which the metal is derived are distinguished by the author into two principal classes, primary iron ores and iron stones. The primary iron ores are defined to be those found in the older formations, bearing little resemblance to those in the stratified planes, and have, in Mr. Mushet's opinion, been formed by secondary agency, although they differ widely from each other in their properties. Some are distinguished as being obedient to the magnet, and others the reverse, but this property is by no means dependent upon the quantity of iron contained in the ore, but on its being in the state of protoxide, united or not with a portion of peroxyde, as ore from the Isle of Elba yielding 70 or 80 per cent. is but slightly affected by the magnet, while many of the Norwegian and Danish ores with only 18 to 30 per cent. of metal are highly magnetic. Mr. Mushet well defines the magnetic property as a test rather of the presence of iron than of the probable quantity to be obtained. The principal localities in England for primary iron ores are Cumberland, and Furness in Lancashire, also in the island of Islay, Muirkirk, and other places in the north, Cornwall, Devon, &c.

The Cumberland ores which present a perfectly formed crystal seem to be formed by the agency of water, an opinion which is countenanced not only by the structure but by several remarkable circumstances, water having been found in cavities of this ore, which had been transported several hundred miles. This ore is generally found, as well as that of Furness, in caverns or churns of the mountain limestone in large masses, splinty and globulated, consisting of various kidney terms called hæmatites, striated and smooth, of bluish and reddish colours. The Lancashire ore is composed of smaller masses, softer and of a more greasy appearance, but highly crystalized. Both of these ores, in the kidney variety, contain fine specimens of graphite or fossil plumbago. The ores both of Cumberland and Furness are much sought after for the purpose of mixing with poorer ores, large quantity of the Furness ore being shipped from Ulverston for South Wales. An opinion has prevailed unfavourable to the working of these ores on the spot, where both coal and limestone are at hand; no effective method of reducing them having yet been employed, although the author of the work before us has on more than one occasion given his weighty testimony as to the practicability. The Islay ore is found regularly stratified, and resembling, in point of deposition, the Norwegian and Danish ores. The strata, as described, are almost vertical, and are found imbedded in a loose ochreous earth surrounded with soil. The ore is not smelted with advantage owing to the excess of silex it contains. In different parts of Scotland, in the West Highlands, at Muirkirk, Salisbury Craggs, La Mancha, Cranston, the Ochil ... &c., small quantities of ore have been found, but no quantity ... ent to justify the working. The chief Cornwall ores found in the granite are those of Lostwithiel, much mixed with quartz and ...ese, and averaging about 46 per cent., and those of Fowey, a hæmatite, with 58 per cent. Those of Devon are the ores of Hayton, containing about 45 per cent. and lying in a schistose formation. We may also notice ...

sandstone, yielding 44 per cent., and at Brixham, yielding 62 per cent. The Devon and Cornwall ores are used extensively in South Wales, as also a rich hæmatite from the neighbourhood of Bristol, containing from 45 to 60 per cent. The iron of ores of the Forest of Dean are found like those of Cumberland in the carboniferous limestone; brush ore is one of the principal varieties, a hydrate, with protoxyde of iron, containing frequently from 60 to 65 per cent. of iron, the leaner ores containing a great deal of calcareous matter in the shape of spar, and so yielding only about 15 or 25 per cent. The Forest of Dean ores are the only ores worked alone, and instead of being treated with limestone, require a mixture of burnt argillaceous schist, as on account of their containing limestone, they are refractory and infusible.

We now come to the iron stones—these are commonly found in horizontal strata, subject to the same acclivity and declivity as the other stratified substances under the surface; their inclination varying according to the nature of the ground, and the disposition of the incumbent strata. They are supposed to be of aqueous origin, and are generally found imbedded in schistous clay more or less compact, which moulders away on being exposed to the atmosphere, and frequently accompany coal and limestone, in immediate contact with the coal. The ores are of two principal forms, in strata from half an inch to twelve inches thick; regularly connected strata called bands, and strata of detached stone found in distinct masses, from the size of a small shot up to a weight of several hundred pounds. The smaller masses being called in Scotland ball stones, and the larger lunkers (qy. lumpers). Band ironstone accompanying limestone is most commonly of inferior quality, its component parts being chiefly calcareous, and the quantity of iron contained being small, while ball iron stones accompanying lime are of much superior quality. The iron stones are divided by Mr. Mushet into four classes. 1. Argillaceous ironstone, which has clay for its chief component earth, and this clay comparatively pure and free from sand. 2. Calcareous ironstone, possessing lime for its chief mixture, and this lime also comparatively destitute of sand. 3. Siliceous ironstones, uniting clay and lime, and containing large proportions of silex. 4. Mixed ironstone, containing nearly an equalized mixture of clay, lime and sand. Each of these classes requires a different treatment dependent on its constituent parts, which with the quality of the fuel are the causes of the great diversity of processes which prevail in the manufacture of iron. Besides these four classes must be mentioned the Mushetstone or Blackband, a carboniferous ironstone, partaking much of the nature of coal as generally it contains carbonaceous matter enough to torrify the stone and make it fit for the furnace. Its exact geological position has not yet been determined, but is supposed by its discoverer to be in the lower part of the coal field near the millstone grit. The usual criterions by which ironstone is judged are—1, the degree of tenacity with which it adheres to the tongue after torrefaction; 2, its colour; 3, the obedience to the magnet when pulverized; 4, by depriving of its iron a given weight of the ore in the assay furnace. The first and third of these methods are peculiarly liable to error, as the degree of adhesion to the tongue will be more in proportion to the quantity and kind of clay contained in the stone, than to its real contents of iron, and the influence of the magnet as before remarked, is equally deceptive. The test by colour, although an empirical method, is one far more to be depended upon. A correct chemical analysis, however, although the surest test, is scarcely ever used, from the ignorance of the manufacturers. Mr. Mushet complains loudly and truly of the deplorable state of scientific knowledge of this class, which is as slow in acquiring instructions as in adopting improvements. He asserts that to his own knowledge the grossest mistakes have been made, and cites one case of iron ores of 30 per cent. having been sold for and smelted as ores containing 60 per cent. Detection it appears in such cases is difficult, as the charge of the furnace often consists of an association of iron ores, iron stones, and scoria from the forge and mill. Nor does the case appear to be much better among those professing some knowledge, as from want of proper instruction they are also open to gross errors. Instruction of this kind therefore seems to be a legitimate object in schools of mining and engineering, the inculcatiob of which would be of more good than all the attempts at teaching practice by theory.

A Practical Treatise on Locomotive Engines. By the Comte de Pambour. London: J. Weale, 1840.

We feel much gratification in being enabled to recommend to the notice of those of our readers who are interested in the theory or practice of locomotive engines, a second edition of this excellent and truly valuable work. The former edition, although conveying, in the form of experiments, more practical information relative to locomotives than any other work which has appeared on the subject, and embodying the results of those experiments in a theory, which, though no perfect, was nevertheless calculated by the soundness of the reasoning in general, to throw much light on the true theory, was still defective in several points. The resistance of the air to the motion of the trains, and that of the extra pressure of the waste steam on the back of the pistons, caused by the blast-pipe, did not enter into the evalution of the work done by the engines. To supply these deficiencies, the author undertook, in the month of August, 1836, some experiments on the Liverpool and Manchester Railway, from the results of which he has deduced formulæ for determining those quantities which had previously been neglected in the calculation of the resistance overcome.

These experiments comprise also several other researches, such as the vaporization of boilers in different circumstances of rest and motion, the effects of different proportions between the fire-box and the tubes on the total vaporization of the engine, and on its consumption of fuel, &c.

In the first edition the loss of steam by the safety valves had been very incorrectly measured; this has suffered a material alteration in the edition now before us, but how far the new determinations are to be depended on, remains yet to be proved. It is an investigation which demands that the experiments should be conducted with the utmost nicety, and in the greatest possible variety of circumstances.

The table of experiments on the quantity of water carried over with the steam in the liquid state, differs in some respects from that which was published in our Journal for December, 1839, and to which we appended a note explaining our reasons for not putting implicit confidence in the results obtained. Two different experiments with the Star engine have been substituted in the work under consideration, for those contained in the table which was published in the Journal, and in all the other experiments which are the same as in that table, we observe that a different deduction has been made for the loss by blowing through the safety-valves during the ascent of the plane. The first of our objections is removed by the indirect statement that there was no loss by leakage during the experiments given in the table, the second in some measure by the corrections in the determination of the loss through the valves, and the last by the declaration, that the mean is only intended to be adopted approximatively for engines that have not been directly submitted to experiment in this respect. This mean has been corrected from 0·68 to 0·76.

The second chapter, which treats of the laws which regulate the mechanical action of the steam, is the same as the corresponding chapter of the "*Theory of the Steam Engine*," by the same author, which was published last year. It has been introduced here in order to save the reader the trouble of recurring to another work, besides which, it has the advantage of rendering unnecessary the purchase of that work to those who are only interested in steam engines in as much as they are applied to the purpose of locomotion on railways, and whose means may be too limited to justify such an addition to their libraries.

We are compelled, for want of time, to postpone a more particular examination of this very interesting work until next month, in the mean time assuring those of our readers who are desirous of making themselves more thoroughly acquainted with the effects of locomotive engines, that they cannot do better than possess themselves of this second edition of Comte de Pambour's Treatise; for those who were unable to obtain the first edition, will be amply recompensed for their disappointment, by the superiority of the new one, and those who possess the former, will find it almost equally necessary to purchase the latter, since it can scarcely be considered as a reproduction of the same work, but almost rather as a continuation of it, so many and important are the corrections and additions which have been introduced.

REPORT ON THE REMOVAL OF THE WEIR AT THE BROOMIELAW BRIDGE, GLASGOW.

By William Bald, F.R.S.E., M.R.I.A., &c., Engineer of the Clyde.

To the Trustees for Improving the River Clyde and the Harbour of the City of Glasgow.

My Lord, and Gentlemen,

In conformity with the remit transmitted to me, dated the 6th instant, I have read over the Report of Captain Johnstone and Mr. Russell, Harbour Masters. It has been drawn up with great care; and from the facts therein stated, is of great value, and merits deep attention. I have no hesitation in signing their report, so far as it treats of the many advantages which would arise from the opening up the spaces between the bridges for the accommodation of the small steamers, sailing craft, &c. But there are other points, in my opinion, of vital importance, connected with this subject, which have not been mentioned in their report; and which I beg leave to lay before your lordship and the trustees.

The removal of the weir at the Broomielaw Bridge, and the deepening and clearing of the space upwards to Stockwell Bridge, containing nearly 14 acres, would give much additional tidal water; thereby increasing the currents not only through the harbour, but also to some extent in every part of the Clyde downwards; thus aiding and assisting that scouring force which acts so powerfully in freeing and keeping clear all river estuary channels from banks and shoals—the great obstacle to navigation. In the improvement of the navigation of tidal rivers, no expense or pains should be spared to increase this scouring force, arising from that uniform and constant tidal flow and run of currents ascending and descending alternately, and which are so eminently distinguished by their beneficial effects in preserving navigable channels, as compared to those violent land-floods, which, in many instances, so frequently carry down immense masses of matter, forming shoals, banks, and bars in them, extremely injurious to the navigation, and involving great expense in keeping them clear.

The removal of the Weir at the Broomielaw Bridge, and the additional receptacle for tidal water between the Bridges, would have a tendency to sweep and scour away all those impurities which are at present discharged into it by the city sewers. The removal of the weir, and the deepening and clearing away of the channel of the river, would also have the effect of lessening the miasma which arises from the present condition of the bed of the Clyde between the bridges, and would render the atmosphere of that part of the city much more pure and healthy.

It is noble and praiseworthy to erect hospitals and asylums for the relief of those who may unfortunately be afflicted with fever; but how much more advantageous would it be to cut off and destroy the sources from which that contagion arises, by the removal of all offensive matter? In this respect, the attention paid by the Dutch to many of their cities and towns, offers an excellent example to the people of other countries.

At present, the harbour of Glasgow is a receptacle, not only for a large portion of the *debris* which the Clyde sends down during floods, but it is also a reservoir for almost the whole of the matter discharged by the city sewerage. The quantity delivered into the present harbour from those two sources is immense.

The flood of last August left a deposit on the steps of the upper ferry-stairs, on the south side of the harbour, as follows:—On the upper step, reached by the flood, a depth of 2 inches; on the descending steps, 2¼, 2⅝, 2¾, 3¼, 4⅜, and 5 inches. The last step was about 3 feet 4 inches below ordinary high water line. It has been alleged, that the River Clyde leaves little or no deposit; but the above facts prove the fallacy of such a statement. Besides, no experienced observer could have a doubt on this subject, who has seen the extremely discoloured state of the water of the Clyde during a flood, by the quantity of alluvium held in suspension, and which is deposited in the bed and sides of the Clyde, wherever the tranquillity of the water is not disturbed by a current sufficient to carry it away;—and it should always be recollected, that, in the improvement of the navigation of a river, and the widening of a harbour through which it runs, a velocity of 3 inches per second at bottom will work on fine clay; that 6 inches per second will lift fine sand; 8 inches per second, sand as coarse as linseed; 12 inches per second will sweep along fine gravel; 24 inches per second, gravel one inch in diameter. These established facts ought to govern the engineer as to the width which should be given to rivers, and to harbours through which rivers flow, so as to regulate the velocity of the water and prevent them from being silted up with alluvial matter, or involve a serious expenditure in keeping them clear by the artificial means of steam-dredging; therefore, no exertion or expense should be spared to increase the natural force of the scouring power, by the descending currents through river harbours and river navigations.

It may be observed, that to keep the harbour of Glasgow clear, and sufficiently deep for vessels sailing out and in, requires at least the power of two steam-dredges constantly working; the annual approximate expense of which is as follows:—

Expense of one dredging-boat per annum, including repair of wear and tear, and interest on capital, at	£1368	9	4
Steam-power drawing the punts	500	0	0
Discharging the material and carrying it away	1200	0	0
Expense of one dredging-vessel	£3068	9	4

Then, the annual expense of two steam dredging-vessels will be about £6,136 18*s.* 8*d.* The area of the wide part of the harbour between Messrs. Todd and Higginbotham's mill, and the Weir at the Broomielaw Bridge, is about twenty-one acres, which requires to be operated on constantly by two steam dredging-vessels: this is nearly equal to the rate of 300*l.* per acre of harbour surface per annum.

Immediately below the Weir, and within the Port, spaces have been cleared and deepened to 10 feet below low-water line, but which have been filled up in the short period of a few months to 2 feet above it; thus filling up a space of 12 feet in height. Looking at the vast expense of keeping the harbour clear—and again, at the great inconvenience to the shipping by a reduced depth of water, arising from shoals and banks being so rapidly formed within it, so extremely detrimental to its free navigation—I am impressed with a more full conviction, that the most active and the most energetic steps should be adopted to diminish those evils as far as practicable. Therefore, the clearing away immediately of the Weir at the Broomielaw Bridge, the widening of the mouth of the Harbour, and the deepening of the River up to Stockwell Bridge, would tend partly to remove the evils here stated, because those operations would increase the tidal currents through the harbour, and equalise them at its mouth.

The matter discharged from the city sewers on the north side into the harbour, might be entirely removed by the construction of a large sewer, commencing near the Jail, and running parallel with the river down to below Barclay's Slip, where it would enter the Clyde. This sewer would receive the whole of the drainage which at present falls into the harbour from the city of Glasgow on the north, and would consequently free the port from considerable deposits which are discharged into it.

The peculiar construction of the present harbour of Glasgow, with its narrow entrance, its head barred by a stone weir extending across from side to side, over which the high tide only sometimes rises but a few inches, so that there is scarcely any perceptible tidal current upwards through it during the whole period of flood tide, until the water has reached above the top of the weir at the Broomielaw Bridge; the water sent up by the tide of flood, as well as the river water descending and falling over the weir into the harbour, remains in a quiescent state, except during the times of floods. Thus, the alluvium contained in the descending waters of the river, the silt carried in by the city sewers, and the fine particles of matter held in suspension by the tidal water flowing up—all meet in the harbour of Glasgow—at every tide, forming immense deposits, undisturbed by any tidal current for more than four hours; which fully accounts for the rapid manner in which the harbour of Glasgow silts up, and the great expense which is constantly required to keep it clear and open by steam dredging-vessels. But if that part of the river between the Broomielaw Bridge and Stockwell Bridge, were deepened, it would receive the river *debris* before it could reach the harbour, and it could be dredged up there as cheaply as any where else, and without any inconvenience to the shipping.

What can be compared to a fine navigable river flowing free and unfettered, without lock or dam, through a city, laying open, by its upper reaches, the rich mineral wealth of the interior country to the enterprise and industry of the people; while, on the other hand, the lower reaches of the river waft the ships to the ocean, that highway to all the regions of the world!

It must be manifest to any person who has observed the immense business which is carried on by small craft, on the waters of the Thames at London between the bridges, on the Seine in Paris, and on many other rivers which run through cities and towns, and the clearing away of the weir at the Broomielaw Bridge, and making the river Clyde navigable through the city, would be a work of the greatest public utility, conferring advantages of the most beneficial kind, not only on the shipping interests, but also on the whole population of Glasgow.

The Govan Railway delivers at the harbour of Glasgow annually from 60 to 65,000 tons of coal; and although this railway will, in my opinion, continue to increase in its traffic, yet I am confident that the opening of the upper navigation of the Clyde would be the means of sending down by water considerable quantities of coal and other minerals, &c. to the shipping in the harbour; and it may be observed, that the descending tidal and river currents—a power which costs nothing—would offer every facility to the transmission of coal and other articles downwards, which could be shipped at once from the barges or punts into the ships and steamers lying in the harbour, without encumbering and occupying so much of the quays, or wearing the streets by the constant cartage of such vast quantities of coal, which are not only required for exportation, but also for the supply of the numerous steamers on the Clyde, and those plying to the ports of England and Ireland. Coal-lighters, carrying about 100 tons, descend the Mersey, enter the docks of Liverpool, and supply the shipping. The facilities to river navigation which the Clyde offers, from the harbour to a considerable distance above the city, into the coal and iron districts, are extremely inviting for the carrying on of a similar traffic.

The space, as already mentioned, between the Stockwell and Broomielaw Bridges, contains an area of nearly 14 acres. The deepening and the construction of wharves within it, would be less expensive, and would afford comparatively more accommodation to the small shipping craft, than any other place which could be found anywhere within the vicinity of the harbour. The expense of the contemplated works will be nearly as follows:—

Masonry, in wharves and quay-walls, 1350 feet long	£17,287	11	6
Deepening channel, paving, cranes, pauls, &c	8,047	17	0
Securing Stockwell Bridge	1,234	11	8
Total	£26,570	0	2

It may be proper to observe, that the deepening between the bridges to two feet below low water line, will not, in my opinion, disturb the foundations of the existing quay-walls in the harbour.

In concluding, it is to be hoped that the space between the Broomielaw and Stockwell Bridges, which is now waste and useless, without a raft of timber, or even a small boat, to adorn its surface, will very soon be covered with numerous classes of small vessels, presenting a scene of a busy maritime trade nearly in the middle of the city. And now that railways are about to compete with the steam-boat passenger trade, what immense advantages would it confer on the steam navigation of the river, if the weir were removed, thereby enabling the steamers sailing to all the lower parts of the Clyde, to arrive and take their departure from between the bridges, or even from the Broomielaw Bridge, which would be so extremely convenient and central to the inhabitants of the city.

BRITISH MUSEUM.—FUNEREAL MEMORIALS OF ROME.

(From the Times.)

There are, perhaps, few rooms in the British Museum whose contents deserve or attract more inquiry and observation among the generality of its visitors than the one appropriated to the funereal memorials of the Romans, and of which less account is given in the meagre synopsis of the institution; the other remains of Grecian or Egyptian antiquity which fill its halls, although possibly placed with sufficient taste and judgment, yet having no connexion with the scenery, if it may be so called, of the localities in which they are contained necessarily lose much of the effect they are calculated to produce. To the artist who contemplates the beauty and boldness of their designs, or the excellence of their execution, and takes them as models for his study, this is perhaps scarcely felt; his taste may discern their value; like the lapidary, he is equally aware of the brilliancy of the gem when it first meets his view, whether disguised by the crust that nature gave it, or set off with all the splendid adjuncts which art or study can devise. Still, even the genius of the artist may become cramped and clouded in its development from contemplating the master-pieces of antiquity isolated and unconnected from the architecture to which they appertain, and when, instead of viewing them as part of a magnificent whole, he sees them but in a state of chaotic vagrancy and isolated decay. In contemplating the minutiæ of beauty displayed in the dilapidated or even in the more perfect remains of antiquity, apart from the designs of which they form but a portion, the imagination necessarily becomes concentrated and confined by that which it contemplates, and however much the taste of the observer may be improved, and however excellent may be the work he in consequence produces, yet in his productions that sense of unity and grandeur of thought is often found wanting, which is the distinguishing feature of ancient art. To this, perhaps, may be attributed those anomalies of design which are to be seen in almost all the classic monumental sculpture of our cathedrals, and also in most of the modern architectural elevations of the Greek and Roman school. The different parts or sections of one or the other will often be found perfect, but few there are that taken as a whole will bear comparison with the edifices or monuments of antiquity. We mention this, because, in the chamber we are about to describe its architecture and decorations, with the exception of the northern side, form a perfect representation of a Roman columbarium, or place of family sepulture; the urns which are in the niches of the walls originally occupied similar positions; the sculptue of few of them possesses pretensions to excellence, and had they been placed in a room among a generality of sculptures, they probably would have caused no observation, or if any, contempt; yet in this chamber, fitted up in resemblance of those in which they were found, they acquire consequence, and well worthy are they of the observation they attract. It is the only part of the Museum in which the sculptures are in connexion with the edifice. and which, from that connexion, give a true idea of the purposes for which they were designed; in the contemplation of them the spectator, without much stretch of imagination, might almost fancy himself in a family sepulchre of ancient Rome, surrounded by the ashes of its members.

This saloon is entered from a door in the northern side of the statue gallery; it is 16 feet in length by 10 in breadth, and the height 10 feet; the roof is vaulted and divided into compartments; the colour gray. On either side, cut in the depth of the wall in lines one above the other, are niches, in which are placed the funeral urns of a family, and on the pavement on the eastern and western sides are some of greater magnitude, and also some smaller ones placed on votive altars; almost all of them are richly sculptured, and the various designs have an allusion either to the mythological dreams of the ancients, or represent some domestic scene: none of them possess that character of awful simplicity which distinguish the last receptacles of our Gothic ancestors. Beneath some of the niches are marble tablets, bearing inscriptions, and where this is the case within the thickness of the walls are enclosed earthen jars, with covers, in which the ashes of the deceased were placed. The floor is formed of Mosaic.

The niche No. 35 contains a sarcophagus, on the front of which the marriage of Cupid and Psyche is sculptured. Of this Apuleius gives the following description :—"The bridegroom in the centre is lying on a couch, Psyche '*gremio suo complexus;*' Jupiter and Juno are in the centre behind in a sitting posture, and all the gods according to their rank are standing around; a bowl of nectar is passing from one to the other. Jupiter has a particular cupbearer to himself to attend and fill. Bacchus waits on the others, while Vulcan cooks the supper; the loaves are strewed with roses and other flowers, and perfumes are scattered over all by the graces: '*Musæ voce canora* ....' Apollo sings to the lyre, while Venus dances in time to soft music, and the graces sing in chorus; the pipe is blown by a satyr, and Pan plays on the reed. The whole of this is a representation of the rites by which Pysche is conferred on Cupid." In this piece of sculpture the principal figures shown are Cupid and Psyche, with their immediate attendants; they are sitting on a couch, in front of which is a small tripod table, on which is a fish; around are the attendants playing on musical instruments in honour of the bride, and bearing to her wine, fruit, and presents: the companion of each of these attendants is represented as a Cupid or a Pysche, for the ancients had many Cupids and more than one Psyche. The ends of the sarcophagus are rounded, the length of it is 4 feet 6 inches, the breadth 18 inches, and the height 15; urn of an oblong form: three fluted spiral columns and two pilasters divide the front into four compartments, in each of which is a door ornamented on the top with pendant garlands of laurel; there are four tablets passing across the upper part, one of which has the following inscription on it:—"2 C. Magio, F., Pal. Heraclidæ V. A. xviii.;" the others are blank. The lid resembles those found on the Etruscan tombs; it is like two lids joined together lengthways; in the centre is an ornament of a rabbit feeding on fruit from a basket, on each side of which ornament is a deer, which a serpent and a dog are attacking in front and rear. The doors are supposed to be the portals of the abodes of departed spirits, they are remarkable as having their pediments of the shape generally chosen for the covers of sepulchral monuments. At the end of the urn are two spears crossed, which probably had some allusion to the youth to whom it is dedicated, who perhaps took delight in the sports of the chase, and who appears to be according to the incription—C. Magius Heraclidæ, of the Palatine tribe, the son of Quintus; it has a handsome pediment, in which are figures of dogs hunting.

The niche which is marked 21 contains an exceedingly curious cinerary urn of baked clay; the bas relief on the front represents the hero Echetles fighting at the battle of Marathon for the Greeks, his arms are a ploughshare. Upon the cover is a female figure asleep in a recumbent position; beneath her head is a pillow. Pausanias gives the following account of the circumstances of the combatant who used so singular a weapon :—"It happened in this battle (as they say) that a man dressed and having the appearance of a peasant, and armed with an agricultural weapon, should appear when the barbarians were prevailing, who when he had slain a number of them should vanish; no one knew him as an Athenian, but others said, according to the oracle, that he was a native of Echetlæum." On the border of the urn there is an inscription over the bas relief, which is slightly cut, and has not been painted. The whole of this urn is exceedingly well designed; there is great spirit shown in the attitude of the figure who has been forced down by the strength of the rustic weapon the effort it is making to rise is true to nature; the figure with the helmet has the arms of a Roman legionary, but the shields of all the combatants are Grecian; much vigour and spirit is displayed in the *melée* of the combat.

No. 13 is a sarcophagus, on which a family is represented mourning over the body of the dead; the corpse is that of a female lying on a couch, which is surrounded by the friends and relations of the deceased: they are exceedingly well grouped, and the expressions of grief are well designed. Beneath the couch are seen the sandals of the departed, as also a wreath which has been used as an ornament to the hair: a dog, probably a favourite, is also introduced, and appears as a mourner. On each side of the sarchophagus is a griffin, resting on its hind legs; the lid and plinth are modern. It formerly stood in the Caprinaca palace at Rome, and has been several times engraved. Montfaucon mentions the sculptures of this monument, as illustrating the Roman manner of lamenting the dead; the two figures close to the couch with their arms extended are alluded to in the passage of Lucan—"*Exacte ad sævas famularum brachia planetus,*" and represent a singular part of the Roman ceremony, the "*exclamatio,*" or calling aloud, on the name of the just departed, intended either to arrest or call back the flight of the soul, or to rouse the dormant spirit in case death should not actually have taken place, that the person might not be exposed to neglect or placed upon the funeral pile while any breath of life might still remain. It might be curious to inquire if the singular custom of the death wake, still so pertinaciously adhered to by the Irish peasantry, and to perform which *decently*, as they call it, the poorest will sacrifice all they possess, and the non-performance of which is looked upon as a sacrilege committed, derived its origin from the custom of ancient, or the priestcraft of modern, Rome. At each end of the sculpture the father and mother of the deceased are standing; an old man at the extreme end holds one hand to his eyes, in the other is a funeral cake. On each side of the female are two children. Altogether there are ten figures in the group. The father is sitting on a stool and the mother in a curule-shaped chair; the head of the father is wrapped in a veil.

No. 34 is an Etruscan cinerary urn of baked clay. The bas relief in front represents the single combat of Eteccles and Polynices, who were both slain in the combat; the first from a wound in the groin, and the latter from a stab in the breast. The female figures standing by the combatants are furies; each hold a torch in one hand, while the other is extended over the antagonist encouraging and inflaming the combat; at each end, on a pilaster, is an Etruscan inscription, which is written from the right to the left in red letters. All the figures have been painted, and some of the colours yet remains. Upon the cover of the monument is a female figure asleep. The action of the whole group is excellent; the warrior who is down has lost his helmet; his hair is curled in the Etruscan fashion. His opponent is more completely armed, and the manner in which he forces the shield from his opponent, and drops his own while he stabs him to the heart, is masterly designed. The expressions on the countenance of each are different; extreme anguish in that of the fallen, and the exultation of victory in the other, are strongly defined; the figure of one of the furies is sandalled, while the other is bare. The representation of the combat as here given exactly corresponds with the account of it by the poet Statius, and it is not unlikely that he was indebted for it to these figures. It is highly probable that this contest was by no means an uncommon subject among the ancient artists. Pausanias says that the representation of it made one of the subjects which ornamented the sarchophagus in which the tyrant Cypselas, of Corinth, was deposited: in that the same author mentions that Polynices is represented as having fallen on his knee, which is the exact attitude here represented"—"*Ex Œdipi filius Polynicem* *in quam collapsum frater Hercules urget.*" Take this sculpture as a whole, it is one of the most splendid specimens of sepulchral urn in existence.

No. 43. This is a sepulchral urn of a square form; in the centre of the front is a tablet, on which is the following inscription:—

"Dis manibus
"Peliæ. Philtatæ
"M. Pilius. eucarpus
"Convgi. B. M.
"fecit, et sibi."

At each of the four corners is an eagle; the lid resembles a pointed roof; in the centre of the face of the urn is a bust of Pelia Philtata, and at the corners are the usual ornaments of honeysuckle flowers. The particular for which this urn is remarkable is a peculiarity in the lid, which is occasioned by a singular custom of the ancients, and sometimes practised in honour of the deceased. When the funeral rites were performed it was the custom at stated periods to visit the ashes of their friends, and to adorn their urns with flowers and garlands, and to offer sacrifices of oil and wine to their manes. In some cases these visits arose from friendship or affection, but the performance of them was often strictly ordered by the will of the deceased, and funds provided for it. In this, in order that it might with greater convenience be complied with, on the top of the lid of the urn a patera is formed, in the bowl of which is an opening through which the wine, oil, and ointments were poured upon the ashes. Propertius says—"Adfert hæc unguenta mihi, sertisque sepulchrum ornabit, custos ad mea busta sedens." Ovid in mentioning libations to the funeral urn says:—

"Jam tamen extincto cineri sua dona ferebant,
"Compositique nepos busta piabat avi."

On the left side of the doorway as you enter is a sepulchral urn dedicated by Flavia Dada, and by Fortunatus, a freed man of the Emperor, to the memory of her deserving husband, and his most worthy father, Admetus, a superintendent of the furniture of the Imperial Palace, and also a freed man. Above this inscription is a bas relief representing the "cœna feralis," or funeral feast. Naked to the waist is the figure of Admetus reclining on a couch; in his left hand he holds a large cup or vessel, and in his right a wreath; according to the Roman custom at feasts, his head is decorated with a garland; two children naked are sitting at his feet; behind is a female attendant, who is supporting his body; the hair of this figure is singularly bound on the front of the head in a knot. All these attendants are dwarfish in their proportions, as was frequently the case when inferior persons or slaves were represented on the ancient sculptures. These representations of the funeral feast are curious and interesting: it is impossible for us to enter into the feelings which dictated them; yet the custom of offering the funeral cake and wine at the present day may have derived its origin from it; we know not in what light the ancients regarded a future existence, but these sculptures sufficiently indicate their hopes, though they show the indistinctness of their ideas; here are the mannied dead, represented as exercising the animal functions of life; elegances are displayed to please the eye, food and wine to gratify the taste, often music to charm the ear, and garlands to perfume the air, and to these enjoyments are added the presence of their friends who are yet in existence; thus the living and the dead, the spiritual and the material world, are associated together in one common act; circumstances are represented in the history of which we can hardly participate or understand, but by which we may perceive that the ancients did entertain notions, though inaccurate and ill-defined, of a future state. The urn is ornamented at the top with garlands, which take the shape of volutes, the ends of which terminate in a rose. The præfericulum and patula are sculptured on the sides of the urn. The top has never been separated from the body; it has a large circular excavation in the middle, about seven inches and a half in diameter.

On the north side of the room, in the niche, the third as you enter, is an urn different from most of the others, and very rarely met with, being square, and of an upright shape; it is enriched by a festoon of laurel leaves. On it is this inscription in four lines:—"Vernasiæ Cycladi. Conivgi optima, vix. ann. xxviii. vitalis, Aug. l. scrib. ev. B." The figures of a man and his wife are represented as standing beneath a portico, the roof of which resembles that of a sepulchral urn; they are in the act of joining hands; between them are the letters F. A. P. Lighted torches, placed in an upright position, form the corners of this urn, each side of which is embellished with a laurel tree; a wreath is placed on the centre of the lid, and a dolphin at each corner. The intention of the portico on the monument is in allusion to the entrance of the habitation of departed spirits, where the wife must take a long farewell of her partner. Among the Romans in the earlier times of the empire their funeral ceremonies were always performed at night, which was formerly also the custom in this country, and the torches at the corners allude to it; and even at a later date when the funerals took place in the day time, lighted ones always formed part of the accompaniment; those placed here are of the sort called "tædæ," being the semblance of a number of fine slips tied together with thongs. The dolphins relate to that superstition of the ancients which supposed that the spirits of the dead were conveyed by them across the seas to the happy abodes of the blessed. Vitalis, who by the inscription erected this monument to the memory of his beloved wife, Vernasia Cyclax, seems to have been a freed man of the Emperor, and a favourite, as he held an office similar to that of private secretary; the letters "F. A. P.," between the figures, denote that the tomb was erected by order of the Ædiles. No. 6, is a small slab let into the wall, it shows the manner in which the memory of the favoured dependents of a family were preserved; on it is this inscription—

ANNIOLENA T. F. MAXIMA	SERVILIA IRENE.

Within the wall which it faces are two ollæ or circular vases of earthenware, somewhat of the shape of the alabaster one near the centre on the south side of the room, in it were deposited the ashes of the two persons whose names are recorded on the slab in front. The lids of these vases alone are visible, which can be taken off, to allow libations to be poured which the pious affection of surviving friends might offer to the memory of the departed. Sometimes in family tombs four or more excavations were made in each niche, in general they are found sufficiently large at the top to allow the urn to be taken out, but occasionally, as in this, they are so constructed at the mouth that the space does not allow of the removal.

In the centre of the room is a mosaic pavement, which in the year 1805 was found on making some repairs under the south-western angle of the Bank of England, about 20 feet west of the westermost gate, opening into Lothbury; it was 11 feet beneath the surface, the design is handsome and well executed, but the workmanship is evidently inferior, and probably that of a native artist. The outer border is composed of pieces of brick. It is not sepulchral, nor is it connected with the other objects here: it evidently, from the cross in the centre, was made after the introduction of Christianity into the island.

On the south side, near the centre compartment of the room, placed on an altar, is a sepulchral urn without either inscription or decoration; it has handles and a cover, the shape is exceedingly elegant, the material of which it is made is the alabaster of the ancients, which is of a yellowish colour with pinkish stripes; near it there is another of the shape of a truncated cone, which has a cover and very small handles; the stripes on it are more strongly defined; the colour is the same, as is also the substance of which it is composed; the height of it is 20 inches, the diameter at the top 8½, and at the bottom 12.

The saloons containing the Elgin and Phigalian marbles have lately, after a variety of trials, been coloured in imitation of rose-coloured Egyptian porphyry, and the roof of grayish granite; time may in some degree reduce the luxuriancy and brilliancy of the colour; at present, perhaps, the rosy warmth which it throws over the apartments somewhat hurts the effect of the sculptures. The brown and dark appearance which time has given to these master-pieces of antiquity is compromised by the blooming walls by which they are surrounded and supported, their look of youthful pretention and roseate bloom but badly harmonizes with the severity of age. The monstrosities of Egypt in the adjoining halls would have been more in keeping with that mythias of colour by which their neighbours in a great degree are eclipsed and overwhelmed.

ON DRY ROT.

I was desirous of taking only a partial view of this subject, and of confining my observations to that species of Dry-rot which is common in new buildings; without encountering what is known by that name, which at one time threatened the extermination of the British Navy, and is by some attributed to the Fungi Sporotrichi, but I attempted in vain to make the distinction.*

The rot which I allude to, might be more properly called the damp-rot, or wet-rot, than the dry-rot, for it appears to arise from *confined moisture;* and the prevention as well as the cure for it, I believe, may consist in merely giving the confined moisture an opportunity to escape, by the admission of air. I do not mean to say that atmospheric air is a specific, by the administering of which rotton wood can be made sound; but I do mean to express my belief, that the introduction of air, even in small quantities, will effectually arrest the destructive progress of the dry-rot.

I will mention two instances now existing of this dry-rot in two new churches, namely, that of Trinity Church, Oswestry, and the New Church at Aberystwith. The former is built of rubble-stone of the neighbourhood, from Sweeney Mountain, which is a free-stone, with a large proportion of mortar; the latter is built of rubble-stone of that neighbourhood, which is of a slaty quality, with a large proportion also of mortar. In both these cases the ends of the pews are closely fitted with framed panels of deal upon damp walls, good oak floors in the former, and I think in the latter also, and risers of deal under the pew doors. The effects of this dry-rot have become very conspicuous in both instances, by an extensive destruction of the wood work, against the walls, and under the doors of the pews: upon removing the panels &c., it was found that a parasitic fungus has made extensive ramifications, and the deal is very much decayed, but the oak has as yet suffered comparatively little injury. I believe, that if a perforated plate containing apertures equal to three or four square inches had been inserted in the upper panel, fixed to the wall in each pew, and the like under each door, the mischief would not have happened; and that if these means of ventilation were resorted to now, they would stop the progress of the dry-rot. But I do not know any thing more certain to produce the dry-rot than what I have just noticed, and consequently nothing could put any expedient for the prevention or cure of the evil to a severer test than to have thus impounded the moisture. A pretty little gothic pattern, weighing three-quarters of a pound, has been

* The following Fungi are considered as the cause of dry-rot:—Boletus lachrymans, Merulius lachrymans, Polyporus destructor, and the genus Sprorotrichum.

prepared and partially put up in Trinity Church, for ventilating the parts affected with dry-rot.

The growth of the parasitic plant, and the decay of the wood coming into contact with it, seeming to be in a great degree contemporaneous, I am not prepared to say which is the cause, and which is the effect of the other; but I think that the growth of the plant takes precedence of the destruction of the wood.

I shall relate two or three facts which have come within my knowledge, because they strengthen my conviction as to the most effectual means for the prevention and cure of the dry-rot.

The usual manner of preparing the walls of a house for skirting-boards, and fixing them, is likely to produce the dry-rot, as thus:—a coat of mortar mixed with pounded glass fills up very closely the space behind the skirting-boards, to prevent mice from having a run there, and a moulded cap of wood is rabbeted and put up for receiving the plain board: on the floor is sprigged down a rib of wood, of about one inch square, for the whole side of a room, without any intermission, and the skirting-board is then scribed and closely fitted to the floor, &c.

In a new house, the walls and the plaister may not be perfectly dry, and the same mischief which has been described in the pews of a church is likely to occur, and does so continually, in the decay of the skirting-boards, particularly on the ground floor; but I think that it happens less frequently when there are arched cellars below, which may carry off some of the moisture. A little of the water in washing the floor, the skirting-board being in a dry state, will find its way behind it, and increase its liability to decay, by impounding a little more moisture.

I have observed this to take place to some extent in fifteen or twenty years after a house has been built, but not perceived till the damage was considerable, because the paint will conceal it. In replacing the skirting-board instead of a continuous rib of wood sprigged on the floor, I have taken pieces of a foot or foot and half in length, leaving a vacant space of two or three inches between them, and not fitting the skirting-boards very closely to the floor, so that a small circulation of air may be preserved; and no decay has occurred in a similar period, at least I can answer for a term of thirty-five years from the erection of the building.

When a new mansion house is to be built, it often happens that a certain quantity of sound timber from an old house is to be made use of, in the shape of beams, joists, &c., and the old beams and joists are apt to be immediately applied to the ground floor, which is a great mistake. An instance of this having occurred within my knowledge, I must give a minute account of facts and consequences in order to bring them to bear on the points which are under consideration.

The front of the house faces the west, and consists of two principal rooms extending length-ways to the right and left of an entrance room, the floors being three steps above the ground; and I am pretty sure that the joists, if not the beams also, were of old timber: the boarded floors were of the best Baltic oak, prepared and finished in the most careful manner. Beneath these front rooms there are no cellars, but arched cellars extend under all the back rooms, which appear to have prevented the evil that I am about to describe as having occurred in the floors of the two principal rooms.

In the course of twenty or twenty-five years from the building of the house, the deal skirting-boards on the outward walls were found to have decayed, particularly on the west, and the floor sunk nearly an inch in some places from the skirting-boards. It was evident that the joists had failed at their insertion into the outward walls. The floor was then taken up for an opening sufficient to admit a man with a lighted candle, who crawled on his hands and knees under the floor, to ascertain the extent of the mischief: the parasitic plant or the dry-rot had got so great a footing, that it became a question whether the whole of the two floors ought not to have been taken up; but it was at length resolved to try the effect of a less expensive operation, which at the present time, after a lapse of ten or fifteen years, seems to have answered perfectly well. Several new oak joists were placed crossways beneath those which had partially failed, and as nearly as conveniently might be to the decayed ends of those joists which had wholly or in part lost their holds upon the outward walls, propping the new joists with bricks, slates, and stones; and the skirting-boards were then replaced in the manner before described.

But the thing on which the greatest reliance is to be placed was the preparation to be made for the circulation of air beneath the floors: plates of iron were cast three inches square, perforated with many holes of a quarter of an inch diameter, four of these plates were applied to each of the two rooms, two distantly from each other, at the two outward sides of the walls, below the floors, and two on either side of the fire-places in the floors, whereby a continual circulation of air was established, and has ever since been kept up: and I conceive that the progress of the dry-rot is stopt, while the supply of air required for the fires is materially assisted.

The disagreeable mouldy smell of dampness accompanying the dry-rot was evident enough as soon as the floor was opened, and continued to be less and less perceptible for months, or perhaps years, through the small grates; but those near the fire-places were covered occasionally: the grates had better have been made of brass one-third or one-fourth of an inch thick. I shall bring forward only one more instance, to prove that confined moisture is the cause of the dry-rot, and I must again be very minute, that I may be the better able to support my suggestions when I attempt to apply them to general purposes.

About the year 1820, or a little later, there was occasion to build a new sitting-room at a farm-house, and the site fixed upon was over a cellar, then roofed as a shed or lean-to: the new floor was approached by four steps out of the kitchen, the walls were built of rubble-stone eighteen inches thick, the size of the room is 14 ft. 8 in. by 11 ft. 6 in.—the floor over a slope, and from four to two feet above the ground, while a grate of seven inches square ventilates the cellar from the north.

The object of this is to show in how short a time the new floor was totally destroyed by the dry-rot, without in any way accounting for it, but from the floor itself. The joists were cut out of sound poplar, probably the upper or inferior parts of trees, and between the joists were nailed slips of wood to support short pieces of boards for grouting in the usual manner of counter-ceiling, the floor was neatly laid with inch poplar boards well seasoned, planed, and of the best quality.

In the course of a few months, I believe, the floor joists, boards, &c. were entirely decayed, excepting a few feet near to the door out of the kitchen, which were only partially so. Although, I believe, that the decay was very rapid, I can only assert from recollection of some other particular occurrences, that in the course of three years the room was built, the one floor laid, that floor decayed, and a new floor put up, which is perfectly sound at the present time, after a lapse of more than 17 years.

The present floor is made of oak beams and joists, and very good poplar boards, without any ceiling or laths and plaister under them.

The way I would account for this extraordinary instance of dry-rot is, that the walls were damp when the first-mentioned floor was laid, and that the counter-ceiling was very damp, that the boards were dry and closely fitted, that a fire was rarely (if ever) used in this room, and that the progress of the dry-rot was extremely swift, as it would be in any case under similar circumstances of confined moisture.

I may mention chamber floors of poplar boards at the present time, over a considerable extent of kitchen and other offices, which have been laid down for thirty-five years, and are as sound now as they ever were: although I have seen poplar boards used as window shelves in inferior apartments, and in some other ways, which have gone into complete decay, grub-eaten or otherwise, in the course of a few years.

The reader who may have waded through the details of facts, which I have thought necessary for my purpose, may wish to have the conclusions drawn from them recapitulated in a few short sentences, as thus:—That wherever joiner's work is to be fitted to newly-built walls, there should be means taken for the circulation of a little air. That the beams and joists used for the ground floor of a house should be of British oak, larch, or best foreign deal. That the ends of beams or joists inserted into the outward walls of a new house, on the ground floor, should be cased with sheet lead, zinc, or cast iron, all impervious to moisture, but not too tightly fitted, for fear of the sap's producing confined moisture; or they might be secured at their ends with cases made on purpose of fire-brick clay, or other clay impervious to moisture. I have used cast-iron sockets and fire-brick cases very satisfactorily. That the wooden ribs upon which the lower edges of the skirting boards are to be nailed should not be in continued lengths, without some intermission. That wherever floors are laid with stone bricks, or slate flags, the skirtings should be made of slate-flags from three-quarters of an inch to one inch in thickness, with one sawed edge. That in servants' halls and other offices, where it may be desirable for the skirting or dado to extend to the height of three feet or more, slate-flags of three-quarters of an inch or one inch thick, might very properly be preferred to wood, but capped with a grooved ledge of wood; those slate-flags being worth only about 9d. the square yard.

Many of the particulars respecting the rooms which have been affected with dry-rot may, as I have observed before, appear trivial, or even ludicrous; but when it is recollected that we have been alluding to facts that occurred fifteen or twenty years ago, and which engaged attention only for the moment, I wish to state what is still to be seen; and more particularly to show, that there was nothing in the position nor dimensions of the room last-mentioned, neither door, window, chimney, nor any other circumstance, whereby such an effect of dry-rot could have been produced or promoted, excepting only by the *confined moisture*, and to which alone the dry-rot is to be attributed.

A simple remedy for any grievance is sometimes unpopular, and you may be advised to poison unwelcome vegetation as you would rats, without considering that poison, like gun-powder or steam, is not a thing to be played with.* Is it not more reasonable to trace a mischief, if possible, to its cause, and by removing or counteracting the cause, endeavour to prevent or arrest the progress of the effect? Suppose that a ship may be liable to dry-rot, from confined moisture and the sap (juice) of unseasoned timber,† the natural remedy would be to give a change and circulation to the stagnant atmosphere by ventilation: I see no reason why dry-rot in a ship might not be prevented or arrested by a sufficient number of small grates, which have been used so successfully about the floors of the two rooms as above described.—*Salopian Journal.*

ON THE ECONOMY OF RAISING WATER FROM COAL MINES ON THE CORNISH PRINCIPLE.

At the annual meeting of the members of the Manchester Geological Society, held at their rooms, on Thursday, the 29th October, Mr. Fairbairn read a communication "On the Economy of raising Water from Coal Mines on the Cornish Principle." In introducing his paper to the meeting, Mr. Fairbairn, after explaining the sections of the engine and pumps made by him for some Belgian coal mines, said, that the improvements introduced of late years into the Cornish engines, were of so important a nature as to be highly worthy the attention of the miners of this district. They had not, till very lately, the slightest conception of the great saving effected by the performance of

* Corrosive sublimate is the only known specific, mineral or vegetable, for preventing the growth of the dry-rot fungi, and which, I believe, has formed the basis of Mr. Kyan's patent.

† Oak would require less seasoning, and be much fitter for use, if it were cut down in winter instead of in spring. I recollect, some fifteen or twenty years ago, observing a sound oak plank in the gable end of a house which was under repair; some of the sap (alburnum) and bark was still on the oak, and very slightly grub-eaten, although it might have been in the building an hundred years, perhaps, or more, on the inside of an outward wall, nogged with bricks, and never had been covered with plaister nor colour of any sort.

the Cornish engines, which was so great that the pressure of steam in the cylinder, which would amount to 7,500lb. per square inch, would raise nearly double the amount of any in the neighbourhood, chiefly from the advantages of the expansive principle adopted in the Cornish engine. Mr. Fairbairn then proceeded with his paper, of which the following is an abstract:—

"*The steam engine performs so important a part in almost all the transactions of man, where great power is required, that the progressive improvements of this mighty agent, indispensable to the miner, must be regarded with interest by all.* By the geologist its improvement will be looked at with additional pleasure, since by its means he is enabled to explore the earth to a much greater depth than he otherwise could have done. For this reason, I have thought it might not be out of place to give here some account of the progress of the steam engine during the last 120 years, mentioning the dates of its leading improvements.

"From the time of Savery and Newcomen, in 1707, to that of Beighton, in 1717, it remained stationary, till 1769, when Smeaton introduced considerable improvements upon atmospheric engines, the average duty from fifteen of which amounted to 5,590,000 lbs., lifted one foot high by a bushel of coal.* These improvements continued; and the duty, in 1772, was raised to 9,450,000 lbs.

"Mr. Watt's improvements commenced in 1776, when the average duty was declared at 21,600,000—more than double that of Smeaton's; and, during the years 1778-9, it was still further increased.

"In 1779, and from that to 1788, Mr. Watt introduced the improvement of working steam expansively, which raised the duty to 26,600,000. From 1788 to 1812, few, if any improvements were made in the Cornish engines; and, provided we except the plunger pole, which was introduced about this time, I question whether the Cornish engineers and miners did not retrograde rather than advance during a period of twenty-four years.

"In 1814 considerable advances were made, which raised the duty to 32,000,000 lbs. During that year, Woolf's engine, with two cylinders, was introduced, which again advanced the duty to 54,000,000 lbs.

"Mr. Woolf, above all others, did most for the Cornish engines, by showing the advantages peculiar to high pressure steam, and prepared for subsequent improvements, which led to the present effective system of expansive working.

"During a period of six years, from 1814 to 1820, Woolf's double cylinder engine maintained its superiority, and gave a higher duty than any other.

"Woolf's engine, in process of time, gave way to others of a better construction. They were introduced by Captain Samuel Grose, whose experiments upon the generation and preservation of heat led to great improvements, and ultimately established a new era in the history of the Cornish engine.

"In 1826, Captain Grose's engine, at Wheal Hope, attained a duty of 62,000,000 lbs.; and, in July of the following year, one of Mr. Woolf's single cylinder engines performed the unprecedented duty of 67 million.

"From this time Captain Grose's improvements were appreciated, and generally introduced; they led to a still greater advance in the duty, which this year reached as high as 87 million lbs.

"Messrs. Lean and Brothers report the duty of a few of the Cornish engines at this time as follow:—

	Millions lbs.
Wheal Towan Engine	87·0
Wheal Hope	74·8
Consols	67·6
Binner Downs	63·5
Consols	61·7
Consols	61·3
Wheal Vor	61·1
Wheal Towan, (Druce's)	59·4
Consols	58·4
Poldice	57·8
Wheal Vor	51·9

These give a mean duty of sixty-four millions of pounds.

"Nothing remarkable took place till 1834, when the duty was raised to 90 millions lbs. Since then, it has continued to increase in the ratio of 90, 100, and 110 millions: and during the last meeting of the British Association, at Glasgow, Mr. Taylor reported the present duty at the unequalled performance of 123, 300,593.

"Having briefly stated the progressive improvements that have taken place in the Cornish system of pumping, I would now direct the attention of the society to the important results which these improvements have produced.

"The quantity of coals consumed by all the engines working at the mines in Cornwall, in the year 1835, was, according to Messrs. Lean and Brothers, 1,069,421 bushels. Now, if we compare this with the number of bushels which would have been consumed to produce the same power in 1814, we should have, for the consumption at that period, 4,049,878 bushels, making a saving of 99,186 tons; which taken at 17*s.* per ton, (the price of coal in Cornwall,) we have the enormous saving of £84,308.

"From the above facts, it cannot be doubted, that the improvements in steam engines, and the consequent saving thus effected in the consumption of fuel, are matters of deep importance. Even in districts where coal is cheap, it is a consideration well worthy of attention; and we are assured by geologists, that the coal of this country, although abundant, will not last for ever."

In the course of a very interesting discussion which followed the reading of the paper, Mr. Fairbairn said, he might mention that so great was the saving from the improved system of working the Cornish engines, that it was not improbable that, in this neighbourhood, we might come back to the old system of power for factories. If the duty performed by the Cornish engine was so much more than that of any factory engine in this district, it might be desirable to have a Cornish engine connected with a water-wheel to drive mill machinery.*

Mr. Boothman.—Why not apply it to rotatory motion?—Mr. Fairbairn said, that it would not apply to any thing where the force required was constant. The value of the thing lay in overcoming the inertia of matter. The Cornish engine first raised a weight, and then, by the descent of that weight, it raised the water. That was the whole secret of the Cornish engines.

Mr. P. Clare asked if Mr. Fairbairn had made a calculation of the effective force of the factory engines in this neighbourhood, so as to afford a comparison as to the combustion of coal by them with that of the Cornish engines?—Mr. Fairbairn said, he had done so. The consumption of fuel in our best condensing engines here was 10 lbs. to 12 lbs. per horse power per hour, while the consumption of fuel by the best Cornish engines was only 2½ lbs. per horse power per hour. In other words, we consume four times more coal than the Cornish engines in producing the same effect. The circumstance was most extraordinary; but the facts were before the meeting. The returns of the duty performed were regularly registered in Cornwall, and published monthly, so that any gentleman might see them, in reference to any period; and it would be found, that the performance of the best Cornish engines (for he did not, in reference to this question, speak of the average duty) did not exceed a consumption of 2½ lbs. of coal per horse power per hour.

A Member asked whether there was not some doubt as to the accuracy of the calculations of the duty performed by the Cornish engines, and as to the mode of estimating them?—Mr. Fairbairn said, that the calculations were made upon the area of the bucket and the length of the stroke. He was aware that doubts had been expressed as to the accuracy of the calculations; but they were backed by such authorities, and the returns were so numerous and regular, that he thought their general accuracy could not well be doubted.—The Member observed, that a small quantity of air coming up the pumps would make a difference.—Mr. Fairbairn: No doubt; but still the engine has to lift this great weight of all the pumps and iron work, and the plungers, which must be lifted by the force of steam. He had a return from Mr. Wicksteed, of the East London Water Works, which was not a pit at all; but the Cornish engine there was used to raise water for the supply of the eastern part of London—which return gave a duty of 118,552,475 lbs. raised one foot high; the consumption of fuel being 2·4 lbs. of coal per horse power per hour. Of course he did not speak of the duty performed by these Cornish engines from his own knowledge, but he had every reason to believe the returns substantially correct.—The Member said, he believed some doubts had been repeatedly thrown on the method of calculation.—Mr. Fairbairn said, that some years ago he had been present at a discussion on the subject in the Society of Civil Engineers, when great doubts were expressed, but further documents were brought forward to prove the accuracy of the calculations. However, taking the consumption of fuel by the Cornish engines to be 3 lbs. per horse power per hour, that was a very great difference, as compared with our factory engines.

Mr. Eaton Hodgkinson thought there had undoubtedly been great improvements made in the Cornish engines, chiefly the result of the adoption of the expansion of steam, which they had not been used to any great extent in this neighbourhood, at least till very recently. Whether the returns were quite accurate or not, no one could doubt that the improvements were immense. He thought the plan of making the engine to lift the pump-rods only, and then the descent of the pump-rods lifting up the water, seemed to be a considerable improvement in adaptation. Again, whether Mr. Woolf's plan of the expansion of steam, or that of Mr. Watt, expanding it in the same cylinder, and cutting it off when at a distance of one-fourth or one-fifth down, were adopted, (and it was a question as to which plan was the best,) in both cases there was a great improvement upon former methods. These improvements had a strong bearing upon geology, for were it not for these engines, they could not investigate the strata in mines, for the water would drive them out or drown them. These engines, by draining lakes, might enable the geologist to obtain a great deal of information he must otherwise be without.

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

Tenth Meeting.—*September*, 1840.

(From the Athenæum.)

Section G.—Mechanical Science.

Mr. James Milne gave an account of an instrument termed a *Gas Regulator*, of his invention, by means of which the length of the flame is equalized, notwithstanding the variations of pressure that occur, and a considerable saving in the consumption of gas is effected.

Mr. Coles *on Railway Carriages*.—Mr. Coles proposes to introduce friction wheels; and that, excepting the first and last carriage in the train, the carriages should run on *two* wheels. He also proposes a step-rail at the curves or bends.

"On the Turbine Water-wheel," By Prof. Gordon.

The fundamental principle upon which the construction of the *Turbine-Fourneyron* is based, is that by which the maximum of useful effect is obtained from a given fall of water, depending on the relative velocity of the water and its recipient, which ought to be such that the water enters the wheel

* Duty is a term first used by Mr. Watt for ascertaining the comparative merits of steam engines. In Cornwall it is used for determining the number of millions of pounds of water lifted one foot high by a bushel of coal, (94 lbs.) the time of lifting it not being considered.

* See Mr. Wicksteed's report in the Journal for January last, page 7.—Ed. C. E. and A. Journal.

without shock, and quits it again without velocity. A notion of its construction may readily be formed, by supposing an ordinary water-wheel laid on its side, the water being made to enter from the interior of the wheel by the inner circumference of the crown, flowing along the buckets, and escaping at the outer circumference. Then centrifugal force becomes a substitute for the of gravity. A drawing was here exhibited of a Turbine of about 5 horse force power, the fall being 3 feet, and the expenditure of water 20 cubic feet per second. It was explained that the Turbine consists essentially of—1. A reservoir, the bottom of which is divided into radial compartments by curved plates, serving to guide the water to take a particular direction of efflux. 2. A circular sluice, capable of nicety of adjustment. 3. The wheel with curved buckets, on to which, when the sluice was raised, the water entered at every point of the inner circumference, and flowing along the buckets, escaped at every point of the outer circumference. This latter is a characteristic feature in the Turbines of Fourneyron. Reference was made to the principal Turbines erected in France and Germany,—particularly to that at Inval, near Gisors, and those at Müllbach and Moussay, as illustrative of their use for falls varying from 9 inches to 10 feet. And, again, to those at St. Blasier, in the Black Forest, as instances of high falls,—the one being 70½ feet, the other 345 feet; the one expending 5 cubic feet per second, the other 1 cubic foot per second; the one being 56 horse power, the other very nearly 60 horse power; the one giving an efficiency of upwards of 70, the other of upwards of 80 per cent. of the theoretical effect. A drawing of the latter was exhibited—full size. It is 14½ inches diameter. Its extreme depth or *breast* is ·225 inch, or less than ¼. It makes 2,200 to 2,300 revolutions per minute. It serves a factory, in which are 8,000 water spindles, 34 fine and 36 coarse carding-engines, 2 cleansers, and other accessories. The conclusions drawn by Morier from his experiments on these wheels with the Break dynamometer, or friction strap, are these:—1. That Turbines are with equal advantage applicable for high and for low falls. 2. That their net useful effect equals 70 to 78 per cent. of the theoretical effect of the power. 3. That they may work at speeds varying from

$$n = \frac{3{\cdot}3\ V}{R} \text{ to } n = \frac{5{\cdot}6\ V}{R}$$

Where n = number of revolutions; V = velocity due to fall; R = extreme radius. The useful effect still not differing notably from the maximum. 4. That they work at very considerable depths under water, the relation of useful to theoretical effect not being thereby much diminished.

Mr. Smith (Deanstown) said, there was much in the principle for very high and very low falls, and for varying falls. The principle had been long applied in Perthshire, but in that part of the country a great velocity is obtained at a great expenditure of power.—Prof. Gordon stated, that for all falls above 50 and below 10 feet, the Turbine is to be preferred.—Mr. Fairbairn: The common water-wheel at Gisors, in France, was made by himself and comparative trials were made with it against the Turbine. Mr. Fairbairn was quite satisfied, by Arago's experiments, and otherwise, that the Turbine is a very important machine, and gives a result of 70 to 75 per cent. of the theoretical effect.—Mr. Smith proposed, that as he had peculiar facilities for experimenting on the subject, he, along with Prof. Gordon and Mr. Fairbairn, should investigate the comparative merits of the Turbine and other water-wheels before the next meeting of the Association.

"*On producing True Planes or Surfaces on Metals.*" By Mr. Jos. Whitworth.

Surface plates were exhibited, intended to illustrate the proper mode of preparing surfaces where great accuracy is required. If one be put upon the other, it will float, until by its weight it has excluded some of the air, when they will adhere together with considerable force. These surfaces were got up without grinding. The only operations performed upon them were those of planing, filing, and scraping. Practically, the excellence of a surface consists in the number and equal distribution of the bearing points; the more numerous these are, and the nearer together, the more perfect is their action. But, if a ground surface be carefully examined, the bearing points will be generally found lying together in irregular masses, with extensive cavities intervening. The cause of this irregularity is evident in the unmanageable nature of the process. The action of the grinding powder is under no control. There are no means for securing its equal diffusion, or for modifying its application with reference to the particular condition of different parts of the surface; while the practical result is, that the mechanic neglects the proper use of the file, knowing that grinding will follow, to efface all evidence either of care or neglect. In various departments of the arts and manufactures, the want of improvement in this respect is already felt. The valves of steam engines, for example, the tables of printing presses, stereotype plates, slides of all kinds, require a degree of truth much superior to that they now possess, for want of which there is great waste constantly accruing in time, in steam power, in wear and tear, and, above all, in skill misapplied. The improvements so much to be desired will follow upon the discontinuence of grinding. The surface plate and the scraping tool will then come into vogue, and a new field will be opened to the skill of the mechanic. Supposing him to be provided with a true surface plate, he will find no difficulty, after a little practice, in bringing up his work to the required nicety. For this purpose he will find it advantageous to employ a scraping tool made from a three-sided file, and carefully sharpened on a Turkey stone, the use of which must be frequently repeated. A light colouring matter, such as red chalk and oil, being spread over the surface plate, and the work in hand applied thereto, friction will cause the prominent places to be marked, which will instruct the experienced mechanic where and how to operate to the greatest advantage.

Mr. Scott Russell presented the Report of the Committee *On the Form of Vessels*: the members of this Committee were Sir John Robison, Mr. Smith, (Jordan Hill), and himself.

Since their appointment by the Association, the Committee had been constantly engaged in carrying out the various investigations committed to their charge; and it had been their earnest desire to discharge their duties in such a manner as conclusively to settle the many important practical questions in naval architecture which were matters of uncertainty and dispute, especially in reference to steam navigation. The importance of precise knowledge in constructing a mercantile navy, ships of war, and steam vessels, was reckoned so great, that in almost all civilized kingdoms experiments had been undertaken at the national expense, and Italy, Spain, Sweden, and France had obtained by those means a very superior knowledge of the principles of the construction of ships. In this country the labours of individuals had supplied the only experiments of this nature; and it was matter of regret, that these were not of such a description as to furnish the ship-builder with any certain foundation for rules of art. The new demand upon the invention of the naval architect by the introduction of steam power, had also contributed much to augment the disparity which already subsisted between the data of experimental hydrodynamics and the demands of the practical builder of ships. It had also been thought not improbable, that certain singular phenomena in hydrodynamics, recently discovered, might considerably modify the views hitherto entertained of the nature of fluid resistance; and the Association had, therefore, resolved on the appointment of this Committee, for the purpose of giving this subject a thorough and searching examination. The first subject of concern with the Committee, was the mechanism by which to conduct experiments on a scale sufficiently large to render the results of practical value, and at the same time sufficiently manageable to free the experiments, as far as possible, from elements foreign to the immediate subject of examination. It was desirable to obtain, for experiment, a force capable of moving the vessels subjected to experiment, through the water with an uniform force and velocity capable of being continued for a considerable interval of time over a considerable length of space. All the forms of apparatus hitherto adopted for the purpose of experiment, were examined with the view of adopting the best. None of them appeared fully to answer the end in view, and it became necessary to invent another and better apparatus for giving motion to the vessels. This had been found: a simple contrivance of Mr. Russell's had been adopted, by which a force, perfectly uniform, could be applied without inconvenience throughout any given space, free from the usual errors of friction, rigidity, &c., which had become interwoven with the results of former experiments. This apparatus he regarded as an engine of experiment so important to the future acquisition of knowledge of the resistance of fluids, that he was desirous to communicate it to the distinguished men around him taking an interest in the subject, in order that if it met their approbation, they might avail themselves of it in future investigation. He then proceeded to give a description, with illustrative drawings, of an apparatus by which experiments were made of from a small scale up to 100 feet in length, over a sheet of water from 100 feet to half a mile or a mile in length. For each scale of experiment, strings, cords, and ropes of various thickness were employed; and for the most delicate experiments, a slender Indian fibre, brought home by Sir John Robison, had been found most useful. Two chronometers by Robert, of Paris, also brought over by Sir John Robison, were employed with great advantage, as observations were obtained which could be depended on within two-tenth parts of a second. The next point to be determined was the general method of conducting the experimental inquiry, so as to elicit the most valuable truths, and those most apposite to practical art. For this purpose the most eminent ship-builders were consulted, as to the points upon which they most wanted information, and were requested to point out what were the forms of vessel which they would wish to have tried. More than 100 models of vessels of various sizes, from 30 inches to 25 feet in length, had been constructed. These were drawn through the water with various velocities, and at different degrees of immersion, so as to determine the resistance of all the various forms that might be adopted in practice, and enable the builder to adopt the form best suited to his purpose. A large pile of papers, laid on the table, contained the results of the experiments, which were still continued. Of these experiments, different series were conducted with very various objects. One class regarded the transverse sections of ships; another the water-lines of the bow; another the water-lines of the stern; another the form of ribband-line and of buttock-line; another class, the place of greatest breadth, and so on. From these experiments it resulted that vessels might be made fuller than usual at some points, and finer in others, with great advantage. A peculiar class of lines, called by Mr. Russell "wave lines," appeared best adapted for high velocities both in smooth water and at sea. It also appeared, that the manner in which the particles were displaced by a moving body, and replaced themselves after its passage, was very different from what was generally supposed. There also appeared to be three different conditions of fluid motion and resistance, accompanied with distinct characteristic phenomena: motion slower than that of the wave—motion on the wave—motion on wings of water. The last occurred only at very high velocities, and when two high and beautiful films of water spread themselves in the air, and carried the boat as on gossamer wings along the surface of the water. Mr. Russell concluded the report, by stating, that the experiments would soon be published, and submitted to the examination of those interested in the subject, in a form better adapted to use than that of verbal description. He hoped it would be found that their experiments had gone far to fill up one of the great desiderata of practical science.

Sir John Robison stated, that the whole merit of imagining and conducting the experiments belonged to Mr. Russell.—Mr. Arch. Smith made some observations, disputing the mathematical accuracy of one of the illustrations used by Mr. Russell.—Mr. Russell explained that the physical effect differed in this instance from the mathematical theory.—The Rev. Mr. Brodie had arrived, by calculation, at nearly the same results as Mr. Russell had by experiment. Mr. Brodie hoped Mr. Russell would direct his attention to the phenomena at very high velocities, such as from 25 to 30 miles an hour. Mr. Brodie's calculations have led to such curious conclusions, as to make him suspect some mistake: he was, therefore, anxious that Mr. Russell should prove their accuracy by his delicate experiments.

"*On the Economy of Railways in respect of Gradients.*" By Mr. Vignoles.

Mr. Vignoles stated that this was another subject, in addition to the former one on timber bridges, selected from a general work on the Principles and Economy of Railways, which he was preparing for publication. Looking to the great cost of railways, he had turned his attention to a comparison of the result of the working of railways, with the price paid for various degrees of perfection. He disclaimed asserting that sharp curves or steep gradients were preferable to straight and level lines, but he would endeavour to show that good practicable lines might be and had been constructed, on which trains sufficient for the traffic and public accommodation could and did move at the same, or nearly the same velocities, and with little, if any, additional expense. On an average, the hitherto ascertained cost of the principal lines might be divided thus:—

Land	10	per cent.
Stations and carrying establishment	20	„
Management	10	„
Iron	10	„
Works of construction proper	50	„
	100	

though, of course, these items differed considerably in various railways, but in general it might be said that the works of construction constituted one-half of the whole first cost. He left out, on the present occasion, all consideration of the saving of any of the items, except as to the works of construction; though it would not be difficult to show a reduction on these, to the extent of at least one-half. Mr. Vignoles stated that he had analyzed railway expenses of working, and had reduced them to a mileage,—that is, the average expense per mile, per train, as deduced from several years' experience, and observations of various railways under different circumstances, and with greatly different gradients, some of which lines were enumerated. The result on passenger and light traffic lines was, that the total deductions for expenditure from gross receipts was 3*s.* per mile per train; 2*s.* 6*d.* being the least, and 3*s.* 4*d.* the highest; and that this average seemed to hold good, *irrespective of gradients or curves.* Particular lines might, from local circumstances, differ in detail, but he was satisfied that the following detail was a fair average approximation:—

	s.	*d.*
Daily cost of locomotive power and repairs	1	6
Annual depreciation, sinking fund, and interest on stock, tools, shops, and establishment	0	6
Daily and annual cost in carriage department	0	4
Government duty, office expenses, police, clerks, guards, management, and maintenance of railway	0	8
	3	0

It was not found practicable to distinguish the additional expense, if any, arising from curves or gradients; but as three-fourths of railway expenses were quite independent of these curves, such addition must be small; especially as, on the North Union Railway, a line which had 5 miles out of 22 in the gradients of 1 in 100, or nearly 53 feet per mile, the total expenses were less than on the Grand Junction Railway, and several other lines. Mr. Vignoles then proceeded to illustrate, by diagrams, the mode in which the economy might be made in the works of construction, on what he called the *first system*, by the occasional introduction of inclines of 50 and even 60 feet per mile, if not of too great a length; and again, on the *second system*, by introducing entire series of severe gradients, such as those of 30, 35, and 40 feet. On the first system, he had executed the North Union Railway; and had also thus designed all the government railways to the south and west of England. On the second system was the Bolton and Manchester Railway, by the late Mr. Nimmo, Mr. Macneill's government railway lines to the north districts of Ireland; and that engineer had lately altered the Dublin and Kilkenny, and the Dublin and Drogheda Railways, from better but more expensive gradients, to those on the second system; and Mr. Vignoles was about to apply it to the Dublin and Kingstown Railway; and he had set out the whole extent of the Sheffield and Manchester Railway, for 40 miles, on an average gradient of nearly 40 feet per mile, mixed with occasional inclinations of 1 in 100, and with curves of one-third mile radius. That work was now under execution by Mr. Locke, who had succeeded Mr. Vignoles as engineer, and who fully concurred in the general principles,—which, as also the details, and the introduction of timber viaducts on a large scale for economy, Mr. Nicholas Wood approved. Mr. Gibbs had also adopted the same system on the first ten miles eastward of the Newcastle and Carlisle Railway. Mr. Vignoles went on to state, that, on either one or both of these systems, introduced as might be considered most advantageous by the directing engineer, lines of railway might be laid out so as not to exceed 10,000*l.* per mile, being particularly applicable where fertile, populous, and manufacturing districts, or the metropolis, with the extremes of the empire, had to be connected through difficult and unproductive districts. Mr. Vignoles concluded by remarking, that when a continued stream of heavy traffic justified the expense, he saw no reason to vary from the general rules adopted hitherto by engineers for laying out railways, or from his own former opinions and practice. But it was forced on him by daily experience, that, to accommodate the public convenience, the Post Office arrangements, and business in general, it was scarcely once in twenty times that a locomotive engine went out with more than half its load, and in general the engines were only worked up to two-fifths of their full power: he was, therefore, conclusively of opinion, that it was much cheaper to put on additional engines on extraordinary occasions; and on such principle railways should be constructed through the more remote parts of the country, so as to be made in the cheapest possible manner. The possession of all the *profitable* lines of railway by private companies, was likely to throw on the government the *onus* of constructing their lines through such districts, in which case economy was desirable: or, if not to be constructed by the government, then was economy still more important; for Scotland, Ireland, Wales, and western and eastern England would want railways, until some such system as those now promulgated could be brought to bear in the laying out lines of internal communication.

Mr. Roberts entirely concurred with Mr. Vignoles with regard to the gradients and curves, as also to the propriety of the economy of adopting timber bridges, and so reducing the price of conveyance to the public.—Mr. Vignoles being asked whether, in the gradients of 1 in 100, on the North Union line, any practical danger was to be apprehended, stated that no danger whatever was apprehended; and that, on these gradients of 1 in 100, the trains travelled *down* at full speed, or about forty miles per hour.

Mr. Jeffreys described a *fire-grate*, exhibited in the model-room, which may be placed, he said, so far forwards as to be quite out of the chimney, and radiate a two-fold quantity of heat into the apartment; and yet there shall be no tendency to send smoke into the room. By an addition, in accordance with the same principle, fresh air is introduced, comfortably warmed before it enters the room.

"*Timber Bridges.*"

Mr. Mitchell observed, that Mr. Vignoles having drawn attention to the subject of *Timber Bridges*, with reference to their application to the economical construction of Railways, he begged to report the result of some experience in works of this nature in the Highlands of Scotland. About twelve years ago he had erected a bridge across the Spey, consisting of an arch of 100 feet span; another about six years since of two arches of 100 feet span, with stone abutments and piers; a third across the Dee, of five arches of 75 feet span, with timber piers; besides a number of others of smaller dimensions. Economy was the chief object in building bridges of this material. It was found they were one-third less expensive; that across the Dee with timber piers less than half: the period of duration he found to be from thirty to forty years; the accumulated value of the saving being more than equivalent to rebuilding the structure. In his opinion, viaducts of this material might be beneficially applied in the construction of railways, of course being suitably constructed to resist the violent action and heavy weights of railway trains. He was glad to hear that Mr. Vignoles considered that railways might be constructed with gradients so much steeper than what has been hitherto considered practically advantageous. Of course, there could be but one opinion about the propriety of a level and direct line both for safety and speed: but the subject was of great importance to Scotland, where neither the country admits nor the traffic demands such perfect construction. He thought practical experiments should be made on the amount of locomotive traction at different inclinations, and with different rates of speed; it appears that hitherto engineers had acted more by theory than observation. One fact he would mention. On a railway recently constructed, he found, that with inclinations of from 1 in 70 to 1 in 100, locomotives travelled nearly at full speed, and at one point, an inclined plane of half a mile with a gradient of 1 in 22, a train of loaded carriages, with a gross weight of thirty-five tons, was drawn up with ease, of course at a reduced speed, but not such as to affect the general rate of travelling; the carriages also passed along curves with radii less than 500 feet.

"*On the application of Native Alloy for Compass Pivots.*" By Capt. E. J. Johnson, R.N.

Among those portions of a ship's compass which most affect its working are the pivots and caps on which the needle and card traverse, and which, like the balance of a chronometer (but of far more importance to the practical navigator), should not only be fitted with the most scrupulous attention to accuracy, but be made of materials capable of maintaining a given form under the trials to which such instruments are necessarily exposed. Having examined a great variety of compasses which had been used at sea, wherein Capt. Johnson noticed that their pivots were generally injured, and often by rust, he searched numerous records of experiments for its prevention, and for improving the quality of steel in other respects, by means of alloys of platinum, palladium, silver, &c. (he alluded particularly to the experiments of Dr.

Faraday and Mr. Stoddart); and Mr. Pepys having obligingly supplied Capt. Johnson with specimens of similar kinds of steel to those used by them, these examples, together with pivots made of the ordinary kind of steel, and hardened and tempered in the manner recommended by eminent instrument-makers, were placed in a frame for experiment; and to these again Captain Johnson added certain contrivances of his own, such as rubbing a steel pivot with sal-ammoniac, then dipping it into zinc in a state of fusion, and afterwards changing the extreme point. Some specimens he coated with a mixture of powdered zinc, oil of tar, and turpentine; and others again were set in zinc pillars, having small zinc caps, through which the extreme point of the pivot protruded after the manner of black lead through pencil tubes. The whole of the specimens were then placed in a cellar, occasionally exposed to the open air, examined from time to time during more than half a year, and their several states, as respected oxidation, duly registered. Without going into the details of this register, the general result was, that not any of the kinds of steel pivots used in this trial, except such as were coated with zinc, remained free from rust, while the pivot made of the "native alloy" which is found with platinum, completely retained its brilliancy. Captain Johnson then applied a more severe test to this singular substance, first, by placing sulphuric acid, and then nitro-muriatic acid upon it; but even under this trial he could not observe that any change had been effected, although the blade of a penknife, subjected to a similar process, was rusted to the centre. Having enumerated the facts respecting the trials to which he had subjected this curious material, Capt. Johnson stated the conclusion that he had come to, namely, that it is sufficiently tough not to break, and hard enough not to bend, under the trials to which it would be *fairly* exposed; and that being alike free from magnetic properties and liability to oxidation from exposure to the atmosphere, it possesses the requisite qualities for the pivot of the mariner's compass; and he could not but anticipate that, when fitted with a ruby cap to correspond, it would be found greatly to improve the working. Besides the application of this substance for compass pivots, Capt. Johnson stated that it might probably be found advantageous for other instruments, and especially for the points of the axes of the dipping needles fitted, on Mr. Fox's plan, for use on board ship.

Mr. Hawkins has used this "native alloy" for several years in tipping the points of pens, and not a single instance exists of any of these pens showing the least symptom of wear. He tried native alloy on a cap, in comparison with ruby, when he found that in the same circumstances, the ruby was ground away with diamond dust twice as rapidly as the native alloy. He had made engravers' tools of the same metal, and when made too sharp they cannot be blunted on the Turkey stone, but only by diamond dust.—Sir J. Robison could bear testimony to one of Mr. Hawkins's pens, which he had used for years, not being at all changed.—Mr. Hawkins stated that this alloy consists of native crystals of osmium and iridium in conjunction with platinum.

Mr. Lang "*On an Improvement on the Air Pump.*" A letter from this gentleman was read, but from some mistake, the paper itself had not been received.

INSTITUTION OF CIVIL ENGINEERS.

"*On the Properties and Chemical Constitution of Coal, with Remarks on the Methods of increasing its Calorific Effect, and preventing the Loss which occurs during its Combustion.*" By Charles Hood, F.R.A.S., &c.

It appears that, previous even to the invasion of the Romans, coal was used as a fuel in Great Britain; but such was the prejudice against it, that wood was the fuel generally in use among the higher classes until the eighteenth century, when the supply of it diminished so considerably as to render necessary the substitution of coal; and from that time the increase in its consumption has been immense.

Previously to the seventeenth century, the smelting of iron and all other metals was performed by charcoal; but the attempts of Sturtevant and Ravenson in 1612-13, and of Dudley in 1619, to introduce the use of coal or coke in blast furnaces having proved the possibility of success, the progress of the innovation, though slow, was certain, and led to the transfer of the iron works from many of the original positions in the midst of forests to the coal districts where they are now placed.

The author considers his subject under three heads:—1st, The chemical character and composition of coal; 2ndly, Its properties as a combustible; and 3dly, The nature and application of its various gaseous products.

1st. The opinion that coal is a compound of carbon and bitumen has been objected to by some chemists, on the ground that by no process hitherto pursued in analyses has it been possible to resolve it entirely into these two substances; even at a low temperature a quantity of gaseous matter is thrown off, and at an elevated degree of heat an evident decomposition of the bitumen takes place. Even anthracite contains a small portion of volatile matter, its component parts being carbon, oxygen, hydrogen, and nitrogen; the hydrogen being either combined with the oxygen to form water, or with a small portion of carbon to form carburetted hydrogen, which exists in a gaseous state in the pores of the coal. In bituminous coal, the hydrogen is combined with a larger proportion of oxygen and nitrogen; the mechanical difference being, that the bituminous and free-burning coals (more particularly) melt by heat when the bitumen reaches the boiling point, whereas anthracite is not fusible, nor will it change its form, until it is exposed to a much higher degree of temperature.

Two tables of the analyses of different coals are given from the authorities of Mushet, Thomson, Vanuxem, Daniell, Ure, and Regnault; No. 1 showing the proportions of carbon, ashes, and volatile matter, with the specific gravity of the coal and of the coke; and No. 2 showing the proportions of carbon, hydrogen, azote, and oxygen. These tables show that the largest quantity of carbon (92·87) is contained in the Kilkenny anthracite, and the least quantity (64·72) in Cannel coal; and that the nature of the volatile matter greatly affects the quantity of coke—the aggregate quantity of the gaseous products of coking, splint, and cherry coal, being very nearly similar; while the quantity of coke obtained from these different species varies more than 15 per cent.

The author then points out the continual presence of azote, which quits the base with the greatest difficulty; and also the affinity of sulphur, not only for the coal, but for the coke, as it is rarely found to have been completely expelled, even from the most perfectly made coke; the only coal found to be even partially free from it being anthracite, in some species of which no traces of its presence are found.

2dly. The application of coal as a fuel depends on the chemical change which it undergoes in uniting, by the agency of heat, with some body for which it possesses a powerful affinity. In all ordinary cases this effect is produced by its union with oxygen. When coal is entirely consumed, the carbon is wholly converted into carbonic acid gas and carbonic oxide, and the hydrogen into water in a state of vapour. The atmosphere supplies the necessary oxygen for this purpose; and in this state the products of the combination are nearly or quite invisible, both of them being almost colourless fluids; if, therefore, any smoke be visible, it is the result of imperfect combustion. Some calculations are given to ascertain the amount of loss that is sustained when the smoke escapes unconsumed; from which it appears, that with bituminous coal about 37 or 38 per cent. more heat is produced when the smoke is consumed than when it escapes freely. Many modes of consuming smoke have been attempted; those which appear to have been attended with the greatest success are—1st. Causing the smoke from the fresh coals to pass through or over that portion of the fuel which is more perfectly ignited; 2dly. Supplying heated air to the top of the fuel, as well as admitting cold air through the ash-pit in the usual manner; and 3dly, Throwing a jet of steam into the furnace or into the chimney. The various modes of carrying into effect these plans are briefly alluded to; from them a few may be selected. Robertson's plan was to use inclined furnace bars, where the fresh coals were placed close to the fire-door, and being there partially carbonized, gave out the gas, which, in passing over the mass of incandescent fuel, was ignited, and became active flame, thus economizing fuel and preventing smoke. In this and similar cases, by the slow distillation of the coal, a gas is produced, which not only inflames at a lower temperature than the dense olefiant gas produced by rapid distillation, but which only requires for its combustion a quantity of oxygen never exceeding double its own volume, or ten times its bulk of atmospheric air, while olefiant gas requires three times its own volume of oxygen, or fifteen times its bulk of atmospheric air. The elimination of a gas which burns with so small a portion of oxygen is, therefore, the principal cause of the non-production of smoke in furnaces of this description. The second mode of consuming smoke is founded on the necessity which exists for a large supply of air being requisite to inflame the gases given off from coal by a rapid and intense heat; and this is accomplished by introducing a quantity of heated air above the burning fuel. When a quantity of fuel is thrown into a furnace, the increased thickness of the mass opposes additional resistance to the passage of air through the bars; the temperature of the furnace is lowered, and an increased volume of gas is at the same time given out. If at this moment a quantity of air, heated to the temperature of the gas, be admitted, the gas immediately inflames, and that which would have produced a dense black smoke passes off in the invisible state of carbonic acid gas and vapour of water. Different gases require different degrees of heat to inflame them; and this explains the easy combustibility of the volatile products of coal when the heat is so managed as to produce those gases which inflame at the lowest temperature. A larger quantity of air is required at the time that the coal is first thrown on than at a subsequent period; therefore, when economy is studied, the supply of air should be gradually diminished as the mass approaches an incandescent state. The use of heated air has produced most important results in the manufacture of iron with bituminous coal, and also with anthracite; the latter fuel having been almost neglected until the recent application of this principle of employing heated air to promote its combustion, although it is known to be capable of producing perhaps a more intense heat than any other carbonaceous fuel. The rationale of the third plan of consuming smoke by injecting a jet of steam into the fire or the chimney, is less obvious than the others. In 1805, Mr. Davies Gilbert observed, that whenever the waste steam of one of Trevithick's engines was permitted to escape into the chimney, the smoke from the coal was rendered invisible. Subsequent experiments confirmed this fact; and it was supposed that the steam, being decomposed, furnished oxygen to support combustion. The author combats this opinion, and accounts for the effect by the increased draught of the furnace caused by the jet of steam into the chimney, by which means a larger portion of air is brought into contact with the burning fuel; thus supplying the previous deficiency of oxygen to the fire, and promoting the combustion. As steam is only about half the weight of air at a like temperature, and the power of all gaseous fluids to ascend is "*inversely* as the square roots of their specific gravities," the velocity of its escape by the chimney, compared with common air of the same temperature, is about as 1·4 to 1; therefore the compound mixture of steam, air, and carbonic acid gas, will escape with a considerably increased velocity, and more air must consequently enter the furnace. It appears that about 10 per cent. of the total quantity of steam generated is necessary to effect the combustion of the smoke by this means; therefore, unless the waste steam only be used, the saving of the fuel must be reduced by this amount. Brief mention is made of the experiments of Messrs. Apsley Pellatt, Parkes, and the Chevalier de Pambour, proving that a given quantity of oven coke will produce as much heat as the coal from which it was produced; and of the various kinds of artificial fuels which had been invented, especially that composed of resin and peat coke, of which the author remarks that its combustion probably produces a mechanical effect, as the hydrogen is converted into water in a state of vapour, which escapes through the chimney with a great velocity, and consequently a large quantity of air is drawn into the furnace, and a more perfect combustion of the fuel is the result. In the same manner he accounts for the necessity which exists for having the openings between the bars wider in a furnace in which coke is burned than in one used for coal. In opposition to the general opinion, he considers that less air is required for the consumption of coke than for coal; the carbon only requiring 2½ times its weight of oxygen for its combustion, while the hydrogen contained in coal requires 8 times its weight of oxygen; and the only reason that the openings between the bars are required to be wider in the former than in the latter case, is in consequence of the draught being so much slower during the combustion of coke.

3dly. "On the nature and application of the volatile products of coal." In treating this portion of the subject—many of the observations on which have been necessarily anticipated in the preceding sections—the author traces the application of carburetted hydrogen gas to the purposes of artificial illumination from the year 1798, when its first successful application was made by Murdock at Soho; he then proceeds to Dr. Henry's investigations of the phenomena of its production and combustion; the variation of the intensity of light obtained from carburetted hydrogen, due to the proportion of carbon contained in it; the difference in the gas obtained from different qualities of coal; the superiority of the illuminating power of the gas from Cannel coal; and the still greater power of that produced from the decomposition of oil, which is 2 to 2½ times greater than that of coal gas. He then mentions the other products of coal by distillation, such as ammoniacal liquor, carbonic acid and oxide, sulphuretted hydrogen, tar, essential oil, naphtha, petroleum, asphaltum, and other substances. The paper concludes by pointing out the advantages which would result from the production of such gas as is usually given out at the beginning of the distillation of coal, as it contains 2 volumes of gaseous carbon united with 2 volumes of hydrogen, and its illuminating power is consequently more than double that of ordinary coal gas.

Mr. Parkes observed, that the quantities of air required for the combustion of different fuels as determined in the laboratory and on the large scale of practice, were frequently very different. It might be quite correct that a given weight of coal would require more air for its perfect combustion than the same weight of coke. There was great difficulty in ascertaining the fact practically, under steam-boilers, as the gases given out by the coal must have air supplied to them distinct from that which passed through the grate to ensure their perfect ignition, and many circumstances prevented the consumption of air from being exactly measured. Generally, he had found it necessary to use wider spaces between the grate bars for coke than for coal. In some late experiments very carefully made on a boiler invented by Mr. A. M. Perkins, equal weights of coal and coke required the same time for their destruction on the same grate, the apertures of the damper and ash-pit door, which were used to govern the draught being precisely the same. Coke effected a greater evaporation than coal at similarly rapid and slow rates of combustion; and in every case the temperature of an oil bath at the foot of the chimney was higher with coke than with coal. It must, however, be remarked, that no process had been used to ignite the gases which escaped from the furnace uninflamed. He had tried different kinds of coke, coal, and anthracite at this boiler, and the same fuel in every instance performed a greater evaporative effect at a slow than at a rapid rate of combustion. He thought that much of the air which entered the grate of a boiler passed through the fire unconsumed, for want of time to effect a sufficiently intimate combination with the fuel. In some experiments lately made at Swansea on the properties of anthracite, Dr. Schafhæutl had found from analysis, that no less than 40 per cent. of the products of combustion taken from the chimney consisted of oxygen, yet he had effected the large evaporation of 11 lb. of water with 1 lb. of that fuel.

Mr. Field stated, that Mr. Cooper had expressed an opinion that in the use of coke as a fuel, a less portion of heat reached the chimney than with coal, on account of the large quantity of unconsumed air that passed through the fire, owing to the open spaces necessarily existing between the pieces of such a dry fuel as coke; whereas in a fire made of binding coal, nearly the whole of the air combined with the fuel in its passage through the body of fire.

Mr. Pellatt observed, that although in practice coke appeared to require more air to support combustion than coal did, yet long experience had taught him to believe that when coal was exposed to a rapid combustion, it required more air than coke.

In answer to an observation that some experiments lately made on the measurement of the quantity of air which entered the blast furnaces of Sir John Guest at the Dowlais Iron Works might bear on this subject—Mr. Parey objected to the application of such results to determine the question, as the air is injected with considerable force into a furnace; there is frequently a great reflux of blast from the Tuyers when the *furnace* is working close; whereas when it is working open the flame at the top shows that the passage of the air through the mass of burning fuel is very free, and that consequently a portion of it passes off unconsumed. He had found in his experiments on blast furnaces, that unless there was a redundancy of carbon, and a deficiency of oxygen, there was no chance of making good iron.

May 26th.—The PRESIDENT in the Chair.

The following were balloted for and elected:—Thomas Illman, Joseph Chessborough Dyer, and G. S. Saunderson, as Associates.

"*On a new Mode of Covering Roofs with Planking.*" By William Cubitt, Assoc. Inst. C. E.

The roof itself is framed in the usual manner with principals and purlins, but without rafters. The boards intended for the covering are cut, by means of a circular saw, from planks 7 inches wide by 2½ inches thick, in such manner that each plank makes two boards, the one tapering from its centre towards the edges, the other from its edges towards the centre. The hollow boards are laid side by side, at intervals of 4½ inches, and nailed to the purlins by their centres only, so as to admit of shrinking; the intervening spaces are then covered by the other boards, overlapping 1½ inch on each edge, and nailed in like manner. The covering thus formed presents a series of alternate elevations and depressions, longitudinally from the ridge to the gutter, and consequently the rain falls off very rapidly, and a roof so constructed is easily kept water-tight. The author conceives this to be the most economical mode of using timber for covering, and he has adopted it extensively. The communication was accompanied by a model of the roof and specimens of the boards as they are left by the saw.

"*On Long and Short Connecting-rods for Marine Engines.*"

A letter was read from Ardaseer Cursetjee, of Bombay, inviting a discussion on the relative advantages of long and short connecting rods for marine engines. He was induced to make inquiry on this subject from some observations in a communication to the Institution, relative to the engines of the steam tug the "Alice" (Minutes of Proceedings, page 385). In that paper their superiority is in part attributed to the increased length of the connecting rods. This is the point upon which he requests information, as he conceives that the power of the piston upon the crank is the same whatever may be the medium through which it is transmitted, and the effect to be the same throughout a complete revolution, whether the connecting rod be long or short, except that from the increased angle of a very short connecting rod some additional friction is thrown upon the joints.

On the general construction of the engine of the "Alice," he remarks, that engines of similar form are now used for pumping at the Thames Tunnel under Mr. Brunel's direction; and that a pair of engines of this kind were built by Messrs. Seaward, 13 years ago, for the "Staadt Francfort" steamboat, to ply between Francfort and Coblentz; in this instance, the cylinders were firmly fixed to the bed-plate and sleepers, with the cross bars above the cylinders, thus having one connecting rod only leading to the cranks, which he considers a superior arrangement to that of the engines of the "Alice."

A drawing of the engines of the "Staadt Francfort" accompanies the communication.

A letter was read from Mr. John Cooper, of Dover, describing the effect of the worm (*Teredo navalis*) on several kinds of timber which had been exposed to the action of sea water. The kinds of timber on which the experiments were made were fir, English oak, and African oak; specimens of each sort, some Kyanized and the others unprepared, having been tried under exactly similar circumstances on the piles of the south pier of Dover harbour. The results show that Kyanizing timber does not in any degree protect it; as, after exposure from December 1837 until May 1840, it was found that the worm made equal ravages among all the specimens. The author also tried the process of saturating timber with copperas water, but did not find any good result from it. In July 1835, he placed under water some 2-inch oak planks which had been prepared with copperas; and on examining them in May 1840, they were found to be as much attacked by the worm as the worst specimens of unprepared fir timber which had been exposed for a similar length of time. The African oak resisted the attack of the worm better than either fir or English oak.

It was stated that Teak timber resisted the attacks of the worm and of the white ant, which destroy all other kinds of timber. It is, however, liable to injury from the attacks of barnacles.

"*On the Corrosion of Cast and Wrought Iron in Water.*" By Robert Mallet, Assoc. Inst. C. E., &c.

This communication is one of those forwarded to the Institution in consequence of the Council having considered this subject a suitable one to compete for the Telford Premiums; and the author having been long engaged in making experiments on this subject at the request of the British Association, refers in the introductory part of this paper to the contents of that report, which may be viewed as a "*précis*" of the state of our knowledge on the subject to the year 1839, together with original researches forming the basis of the present results. This communication is accompanied by a short abstrrate set of tables of results; but these laborious investigations being yet in progress, the author directs his special attention to so much only of the subject as may be necessary for their elucidation, divesting his remarks as much as possible of a purely chemical character, and confining them to those practical conclusions which are of immediate use and importance of the engineer.

The tables of results are altogether twelve in number. The first five contain the data and results of the chemical or corroding action of sea and fresh water on cast and wrought iron under five several conditions, during a period of a year and ten months; and these five series of experiments are so coordinate with each other as to form one connected and comparable whole, whence the relative rates and absolute amounts of corrosion of cast and wrought iron—by, 1. clear sea water, 2. foul sea water, 3. clear sea water at temperature 115° F., 4. foul river water, and 5. clear river water—may be ascertained. The corrosive action of water and air combined produces on the surface of cast or wrought iron a state of rust possessing one of the five following characteristics—1. Uniform, 2. uniform with plumbago, 3. local pitted, 4. local pitted, 5. tubular—or of two or more of these characteristic conditions in combination; these facts for 82 different specimens of British and Irish cast iron—together with their original external characters, mode in which they were cast, specific gravity, dimension and weight before and after immersion, loss of weight per square inch of surface, this loss referred to a standard bar, and the weight of water absorbed for clear sea water—compose Table I. The four subsequent tables contain similar results for specimens of iron immersed under the other four conditions mentioned above. These five tables contain also the results of the corrosion of certain cast iron protected by either of ten several paints or varnishes, the results of which are comparable with those for the unprotected iron. Table VI. exhibits the general comparison of the results set forth in the preceding tables for specimens of iron one inch thick, and reduced to one common or equal period of immersion. Table VII. shows the *average loss* of all varieties of cast iron experimented on per square inch of surface. Table VIII. the average calculated amount of corrosion (assumed uniform) of various specimens of cast and wrought iron per superficial foot of surface at the end of one century. From these tables it appears, that the metallic destruction or corrosion of the iron is a maximum in clear sea water of the temperature of 115° F.—that it is nearly as great in foul sea water—and a minimum in clear fresh river water.

Iron under certain circumstances is subject to a peculiar increase of corrosive action—as, for instance, cast iron piling at the mouth of tidal rivers—from the following cause. The salt water being of greater density than the fresh, forms at certain times of tide an under current, while the upper or surface water is fresh; these two strata of different constitutions coming in contact with the metal, a voltaic pile of one solid and two fluid elements is formed; one portion of the metal will be in a positive state of electrical action with respect to the other, and the corrosive action on the former portion is augmented. The lower end of an iron pile, for instance, under the circumstances just mentioned, will be positive with respect to the other, and the corrosion of the lower part will be augmented by the negative state of the upper portion, while the upper will be *itself* preserved in the same proportion. From this theoretical view may be deduced the important practical conclusion, that the lower parts of all castings subject to this increased action should have increased scantling.

The increased corrosive action of *foul sea* water may be referred to the quantity of hydrosulphuric acid disengaged from putrifying animal matter in the mud, converting the hydrated oxides and carbonate of iron into various sulphurets, which again are rapidly oxidized further under certain conditions, and becoming *sulphates* are washed away. Hence the rapid decay of iron in the sewage of large cities, and of the bolts of marine engines exposed to the bilge water. The corrosive action being least in fresh water may be partly referred to this being a worse voltaic conducting fluid than salt water.

It appears also that wrought iron suffers the greatest loss by corrosion in hot sea water; which fact has led the author to inquiries, with reference to marine boilers, at what point of concentration of the salt water, whether when most dilute, after the common salt has begun to deposit, or at a farther stage of concentration, the corrosive action on wrought iron is the greatest, and he points out the important practical use which can be made of this information. It appears also, that the removal of the exterior *skin* of a casting greatly increases the corrosive action of salt water and its combined air, so that the index of corrosion under these circumstances is not much less than that of wrought iron, and in clear river water is greater.

It further appears, that chilled cast iron corrodes faster than the same sort of cast iron cast in green sand, and that the size, scantling, and perhaps form of a casting, are elements in the rate of its corrosion in water. The explanation of these facts is to be found in the want of homogenity of substance, and the consequent formation of numerous voltaic couples, by whose action the corrosion is promoted. It is also observable that the corroded surface of all these chilled specimens is tubular.

It appears also that, in castings of equal weight, those of massive scantling have proportionately greater durability than those of attenuated ribs and feathers. Hence appears also the great advantage of having all castings, particularly those intended to be submerged, *cooled in the sand*, so as to insure the greatest possible uniformity of texture. The principles now stated afford an explanation of the fact often observed, that the back ribs of cast iron sheet piling decay much faster than the faces of the piles. It is also probable that castings in dry sand and loam will, for these reasons, be more durable than those cast in green sand. The general result of all these experiments gives a preference to the Welsh cast iron for aquatic purposes, and to those which possess closeness of grain. Generally, the more homogeneous, the denser and closer grained, and the less graphytic, the smaller is the index of corrosion for any given specimen or make of cast iron.

The author next proceeds to the important question of the protection afforded by paints and varnishes. White lead perishes at once in foul water, both fresh and salt; and caoutchouc dissolved in petroleum appears the most durable in hot water, and asphaltum varnish or boiled coal tar laid on while the iron is hot under all circumstances. The zinc paint, which is now so much noticed as an article of commerce, the author has analyzed, and states its composition as—

Sulphuret lead	9·05
Oxide zinc	4·15
Metallic zinc	81·71
Sesqui-oxide iron	0·14
Silica	1·81
Carbon	1·20
Loss	1·94
	100·

It may, *a priori*, be considered likely to produce a most excellent body for a sound and durable paint under water. The black oxide of manganese has no advantages but that of being a powerful drier. The defects of all oil paints arise from the instability of their bases; the acids which enter into the constitution of all fixed oils readily quit their weakly positive organic bases to form salts with the oxides of the metal on which they may be laid. Hence we must look for improvements in our paints to those substances among the organic groups which have greater stability than the fat or fixed oils, and which, in the place of being acid or Haloid, are basic or neutral. The heavy oily matter obtained from the distillation of resin, called "resenion," and eupion, obtained from rapeseed oil, have valuable properties as the bases of paints.

Tables IX. and X. contain the results as to the corrosion of cast iron in sea water when exposed in Voltaic contact with various alloys of copper and zinc, copper and tin, or either of these metals separately, per square inch of surface. It appears that neither brass nor gun metal has any electro-chemical protective power over iron in water, but on the contrary promotes its corrosion. This question is only a particular case of the following general question: viz. if there be three metals, A. B. C., whereof A. is electro-positive, and C. electro-negative, with respect to B., and capable of forming various alloys, 2 A + C. . . . A + C. . . . A + 2 C; then if B. be immersed in a solvent fluid in the presence of A., B. will be electro-chemically preserved, and A. corroded, and *vice versa*. If B. be so immersed in the presence of C., B. will be dissolved or corroded, and C. electro-chemically preserved; the amount of loss sustained in either case being determined according to Faraday's "general law of Volta-equivalents." The tables show that the loss sustained by cast iron in sea water, as compared to the loss sustained by an equal surface of the same cast iron in contact with copper, is 8·23 : 11·37; and when the cast iron was in contact with an alloy containing 7 atoms of copper and 1 of zinc, the ratio was 8·23 : 13·21; so that the addition in this proportion of an electro-*positive* metal to the copper produces an alloy (a new metal, in fact) with higher electro-negative powers, in respect to cast iron, than copper itself. The author discusses many results equally remarkable, and is therefore enabled to suggest by its chemical notation the alloy of "no action," or that which in the presence of iron and a solvent would neither accelerate nor retard its solution, one of the components of this alloy being slightly electro-negative, and the other slighly electro-positive, with respect to cast iron. These results will also enable some advances to be made towards the solution of the important problem proposed by the author in his former report, viz. "the obtaining a mode of electro-chemical protection, such that while the metal (iron) shall be preserved, the protector shall not be acted on, and the protection of which shall be invariable."

Table X. exhibits especially the results of the action of sea water on cast iron in the presence of copper and tin or their alloys. It appears that copper and tin being *both* electro-negative with respect to cast iron, all their alloys increase or accelerate the rate of corrosion of cast iron in a solvent, though in very variable degrees; the maximum increase is produced by tin alone, thus indicating that this metal (contrary to what was previously believed) is more electro-negative to *cast iron than copper*. Hence the important practical deduction, that, where submerged, wrought iron must be in contact with either alloy, viz. brass or gun metal; common brass, or copper and zinc, is much to be preferred. These experiments will also serve to demonstrate the fallacy of many of the patented so-called preservatives from oxidation, which are brought before the public with so much parade.

The author lastly proceeds to the subject of the specific gravity of cast iron, tables of which are added to the preceding. The specific gravities here recorded were taken on equal sized cubes of the several cast irons cut by the planing machine, from bars of equal size, cast at the same temperature, in the same way, and cooled in equal times. Many of these results differ considerably from those given by Dr. Thompson and Mr. Fairbairn; which the author refers to the probability that those of Dr. Thompson were taken from pieces of the raw pig, and those of Mr. Fairbairn by weighing in air equal bulks cut from the mass by the chisel and file, by which latter process the volume is liable to condensation. The experiments of Mr. Fairbairn and Mr.

Eaton Hodgkinson seem to show that the ultimate strength of cast iron is in the ratio of some function of the specific gravity dependant upon the following conditions: viz. 1. the bulk of the casting; 2. the depth or head of metal under which the casting was made; 3. the temperature at which the iron was poured into the mould; 4. the rate at which the casting was cooled.

Table XI. All the irons experimented on are arranged in classes, according to the character of the fracture; for which purpose the terms—1. silvery, 2. micaceous, 3. mottled, 4. bright grey, 5. dull grey, and 6. dark grey, have been adopted by the author as a sufficient basis on which to rest a uniform system of nomenclature for the physical characters of all cast irons, as recognisable by their fracture; and it is to be wished that experimenters in future would adopt this or some other uniform system of description, in place of the vague and often incorrect characteristics commonly attached to the appearance of the *fracture* of cast iron.

The twelfth and last table contains the results of a set of experiments on the important subject of the increase of density conferred on cast iron, by being cast under a considerable head of metal, the amount of which condensation had not been previously reduced to numbers. It shows this increase of density in large castings, for every 2 feet in depth, from 2 to 14 feet deep of metal.

A very rapid increase of density takes place at first, and below 4 feet in depth a nearly uniform increment of condensation.

The importance of these results is obvious; for, if the ultimate cohesion of castings is as some function of their specific gravity, the results of experiments in relation to strength, *made on castings of different magnitudes, or cast under different heads*, can only be made comparable by involving their variable specific gravities in the calculation.

June 2—The President in the Chair.

The following were balloted for and elected:—Lieutenant T. H. Sale, B.E., and George Larmer, as Associates.

June 16—The President in the Chair.

The following were balloted for and elected:—William Jory Henwood, as a Member; John Thomas Cooper and John Oliver York, as Associates.

"*On the Action of Steam as a Moving Power in the Cornish Single Pumping Engine.*" By Josiah Parkes, M. Inst. C. E.

In this communication, the author presents a detailed analysis of some of the facts collected and recorded by him in his former communications, with the special object of ascertaining from the known consumption of water as steam, the whole quantity of action developed—the quantity of action had it been used unexpansively—the value of expansion—the correspondence between the power, and the resistance overcome—and, finally, a theory of the steam action, with a view of determining the real causes of the economy of the Cornish single pumping engine.

The data employed for the purposes of this investigation are those obtained from the Huel Towan engine by Mr. Henwood, from the Holmbush by Mr. Wicksteed, and from the Fowey Consols, and recorded in the author's communications in the Transactions of the Institution of Civil Engineers, Vols. 2 and 3.

Steam may be applied in one or other of the two following modes: expansively, that is, when admitted into the cylinder at a pressure greater than the resistance, and quitting it at a pressure less than the resistance; or unexpansively, that is, when its pressure on the piston is equal to the resistance throughout the stroke. By the term *economy* in the use of steam, is meant the increase in quantity of action obtained by the adoption of that mode which produces the greatest effect.

The weight of pump-rods, &c., which effects the pumping or return stroke in a Cornish engine is greater than the weight of the column of water, by the amounts necessary to overcome the friction of the water in the pipes—to displace the water at the velocity of the stroke—to overcome the friction of the pitwork, and of the engine itself. The absolute resistance opposed to the steam, consists of the weight which performs the return stroke, plus the friction of the engine and pitwork, and the elasticity of the uncondensed steam.

The water-load in the Huel Towan engine was very accurately ascertained as 11 lbs. per square inch on the piston; and it is shown that the additional resistance amounted to 7 lbs. in the Huel Towan, and to 6 lbs. in the other engines, so that the whole resistance in the Huel Towan engine is 18 lbs. per square inch of the piston. Now, the elastic force of the steam at the termination of the stroke, and before the equilibrium valve is opened (ascertained from the ratio of the volumes of steam and water consumed), is only 7 lbs. per square inch, that is, 4 lbs. less than the water-load alone. The corresponding results for the other two engines are equally remarkable, and show most distinctly that, at the termination of the stroke, the pressure of the steam is far below the water-load, as had been previously observed by Mr. Henwood and others.

The next step in the analysis is to determine the portion of the stroke performed when the pressure of the steam in the cylinder is just below the resistance, and then to separate and estimate the spaces through which the piston is driven respectively by steam of a pressure not less than the resistance, and less than the resistance. These facts being ascertained, the virtual or useful expansion, and the dynamic efficiency of the steam, during the two portions of the stroke, are known; and it appears that there is a deficiency of power, as compared with the resistance overcome, of above 3 lbs. in the Huel Towan, and more than 4 lbs. in the other engines, per square inch on the piston.

From these startling facts, and a careful examination of Mr. Henwood's indicator diagrams, the author was induced to inquire whether the piston had not been impelled by a force altogether distinct from the continuous action of the steam upon it, namely, by a force which is to be referred to the sudden impact on the piston when the admission valve is so fully and instantaneously opened, as it is in these engines, and a free communication established between the cylinder and the boiler. To this instantaneous action on the piston, the author, for the sake of distinction, assigns the term *percussion*; and, proceeding to analyse the authentic facts under this view, it appears that the space of the cylinder though which the piston was carried by virtue of this percussive action was about 21 inches in the Huel Towan, 27 inches in the Holmbush, and 33 inches in the Fowey Consols engines.

The results thus unfolded, which are facts independent of any hypothesis, appear less startling on a full consideration of the circumstances under which the steam is admitted into the cylinder. The engine has completed a stroke, and is brought to rest by the cushion of steam between the piston and the cylinder cover; a vacuum is formed on the other side of the piston; the elastic force of the steam in the cushion then nearly balances the resistance. A communication is now suddenly opened between the cylinder and the boiler containing steam of a high elasticity; and the piston, being ready to move with a slightly increased pressure, receives a violent impulse from the steam's instantaneous action. The piston having started, the influx of the steam is more or less retarded by the throttle valve, and its elastic force, though at first greater than the resistance, is soon reduced considerably below it, the mass of matter in motion acting the part of a fly wheel, absorbing the excess of the initial power over the resistance, and discharging it by degrees until the stroke is completed.

The indicator diagrams, which are the transcripts of the piston's movements, show that such may be the nature of the action on the piston, and the discussion of numerous well-established facts and phenomena, for the Cornish engines, strongly confirms this view of the case. Whatever may be the theory of the steam's action, the fact that the sum of those actions has carried the piston through its course, is certain; and it seems equally certain that the quantity of water as steam which entered the cylinders was insufficient alone to overcome the resistance.

The author then investigates the amount of useful action due to the steam imprisoned between the piston and the cylinder cover, and recovered each stroke, which, for its use in bringing the engine to a state of rest at the end of the return stroke, he terms the *cushion*. This quantity, though small, is appreciable, and its value is assigned for each engine.

The author treats lastly of the evidence furnished by the diagrams of the indicator, and of its utility as a pressure gauge. The communication is accompanied by elaborate tables of the results of the analysis, and an appendix with the calculations worked out in detail.

SCIENTIFIC SOCIETY.

The opening meeting of the present Session was held by the Scientific Society on Thursday evening, Nov. 19, at their rooms in Great Russell-street, Bloomsbury. In the absence of the President, one of the Vice-Presidents, John Stevens, Esq., delivered the annual address, in which, after adverting to the advanced position of the institution, he explained, at some length, its characteristic features, and the peculiar objects which it is designed to promote. The great and known want of adequate facilities for collecting and registering scientific observations, seriously impeded the progress of inductive generalization,—facts are lost for want of channels through which they may be brought to a common centre, and there has never yet been formed a Museum of recorded and classified data, to which the scientific inquirer may resort for evidence to support or subvert theoretical views. The leading purpose of the Scientific Society is to supply this deficiency, but they can only hope to succeed in so arduous an undertaking, by the most active individual exertion, and by the friendly co-operation of those who are interested in the advancement of science. After the address a paper was read on a new discovery in Electrotype. The meeting was numerously attended, both by members and visitors, which evince the interest taken in the proceedings of the society.

KING'S COLLEGE.

We understand that regretting the necessity of refusing many applications for admission of students, whose age and previous character were not sufficiently advanced, into the civil engineering department—and feeling at the same time the advantage of having their previous education directed to those studies, which would ground them in the subjects of the more extensive readings of the senior class, and convinced as well, that even to a general student would be useful, some knowledge of the principle and nature of that mechanism and machinery which is now becoming the subject of every day remark and conversation, without which the education of the gentleman is scarcely complete, the council of the college have established a junior class for students of 14 years and upwards.

ARCHITECTURAL SOCIETY.

The Tenth Session of this Society was opened on the 3rd ult., at their apartments in Lincoln's Inn Fields, with a conversazioné. The President, William Tite, Esq., F.R.S., the Architect of the New Royal Exchange, took the Chair at nine o'clock; when the Secretary, Mr. Grellier, proceeded to read the Report of the Committee, which stated the arrangements made for the lectures and papers of the ensuing session, and announced five prizes for the competition of the student-members, upon the following subjects:—The best architectural composition; the best measured drawing of the front of St. George's Church, Bloomsbury; the best series of architectural sketches produced during the season; the best notes of the lectures delivered at the several meetings of the Society; and the best drawing in chalk or pencil from the plaster figure.

The President then read an elaborate essay on the history, chemistry, and uses of bitumen and its compounds, tracing the facts of their application from the earliest times, with illustrations from the Bible, from Herodotus, Diodorus Siculus, Josephus, Dioscorides, Vitruvius, and Pliny. The lecturer then described the various kinds of bitumen, beginning with its most liquid state of naptha, and descending to petroleum, mineral tar, mineral pitch (sometimes called maltha), and then to the compact bitumen known as asphaltum, elastic bitumen, or mineral caoutchouc, mineral wax, and mineral tallow. This part of the dissertation was illustrated by specimens of most of these substances on the lecture table, and by references to the principal sources from which they are derived in the present day. It appears that, for the purpose of commerce and the arts, they are now obtained from the mines of Avlona in Albania, of Lobsaun in Alsace on the left bank of the Rhine, from Pyremont, which furnishes the asphalte of Seyssel, known in England as Claridge's, besides the asphaltes of the Landes known as the Bastenne and Gaujac. Bitumens, in various states, are also found in great abundance at Rangoon, in the Birman Empire, at Coxitambo in South America, in the famous Pitch-Lake of the Island of Trinidad, in the celebrated Naptha Wells at Baku on the Caspian, in Persia, in Greece, Sweden, Gallicia, Moldavia, Sicily, England, and, in fact, in all parts of the world. In many cases, the varieties are found pure; and in others, as at Seyssel and Lobsaun, they are mixed with argillaceous sands, calciferous bitumens or bituminous grits or shales: all the deposits appear to belong to the tertiary formation. There are various opinions as to their origin; their chemistry, however, would seem to indicate that they must have been derived from the destructive distillation of vegetable matter, the produce of ancient forests. Among other curious facts facts stated by the lecturer, it was mentioned that the streets of Parma are lighted with petroleum from the mines of Avlona; and that a kind of purified bitumen had been, for some centuries, used in Paris for greasing the wheels of carriages, under the name of *graisse noire*.

The introduction of bitumen into mastic, for the purposes of paving, lining tanks, &c., though recently revived in Paris as a novelty, does not appear to be so. Mr. Tite noticed upon this subject, a Tract in the British Museum, entitled, "Dissertation sur l'Asphalte, ou ciment naturel, decouvert depuis quelques années au Val Travers, dans la Comté de Neufchatel, par le Sieur Eirini d'Eyrinys, Professeur Grec, et Docteur en Medecine. Avec la manière de l'employer, tant sur la pierre que sur le bois; et les utilitée de l'huile que l'on en tire." Paris, 1721, 12mo. From this tract the following extracts were read; from which it would seem that the proportions and applications of bitumen in mastic were known more than a century since. "Pour former le ciment, et le mettre en état d'être employé, il faut prendre la mine toute pure, et la bien pulvériser. Pour le faire avec moins de peine et de frais (car elle est fort dure), on peut l'attendrir en la mettant devant le feu, ou à sec dans un chaudière. Dès qu'elle sentira la chaleur, on la broyera très facilement; il vaut, cependant, mieux la piler froide, parcequ'en la chauffant, l'huile s'évapore, et elle perd beaucoup de sa qualité et de sa force.

"Quand elle est absolument écrasée, et réduite comme du terreau, on prend de la poix de Bourgoyne blanche ou noire (la blanche est la meilleure) on la fait fondre a petit feu dans une chaudière de cuivre ou de fer; quand la poix est entièrement fondue, il faut prendre garde que le feu n'y prenne; on y mêle peu à peu l'asphalte en le remuant continuellement avec un bâton ou spatule, jusqu'à ce que l'incorporation soit faite, on le voit parceque l'asphalte doit être liquide comme de la bouillie; la doze de la poix est la dixième partie, c'est à dire, qu'il faut neuf livres de mine et une livre de poix pour former le ciment dans sa perfection."

After giving an account of the manner of employing the asphalte as mortar, the author continues,

"L'on pourroit encore faire des bassins, réservoirs, citernes et terrasses, même sans employer des pierres de taille, et cette façon, qui couteroit moins que les autres, serait aussi solide, et auroit sa [illegible] &c. &c."

His recommendations of the invention are warm:—

[illegible] ciment d'asphalte est fait éxactement, il resiste [illegible] froid; la plus grande ardeur du soleil, ni la gelée n'y peuvent faire aucun dommage. Je crois avoir trouvé la chose du monde [illegible] pour le public, principalement pour Paris, &c. &c."

[illegible] [illegible]bited tables showing the chemical analysis of various [illegible] through the lignites, coals and jets to [illegible] the recent turpentine through the [illegible], down to the asphaltes. He pointed out [illegible] or isomerism of many of these substances, as contrasted with the [illegible] tures; [illegible] the ruins of Babylon and Nineveh, as well as to the ancient Oracles and Nymphaea connected with the springs of Naptha, and particularly to the ruins of Avlona, which seem to connect the ancient Nymphaeum spoken of by Strabo and Dio Cassius, on the banks of the Aias, or Aous, the modern Vioss, with the mineral pitch formation of Selenizza, furnishing the modern asphalte of Avlona.

Mr. Tite explained, at some length, the composition of the asphalte mastics, recommending to the notice of the architects present a careful consideration of their application and introduction.

The lecture was received with the strongest marks of approbation from a very large auditory, including many of the leading members of the Royal Society, the Society of Civil Engineers, the Society of Arts, and the Institute of Architects; and, after the announcement of various donations to the Library and Museum of the Society, the meeting separated.

INTERESTING EXPERIMENTS WITH LOCOMOTIVE ENGINES, ON THE HULL AND SELBY RAILWAY.

On Tuesday, the 10th ult., a course of five days' experiments commenced with the engines of the above Railway, originating through the following circumstances:—

About the commencement of the present year, six engines, somewhat similar to those on the Leeds and Selby line, were in a greater or less state of forwardness for the Hull and Selby Railway, at the works of Messrs. Fenton, Murray, and Jackson, of this town, when the Hull and Selby Railway Company resolved to have six other engines, on the most approved construction which experience up to that period could produce, from the previous working of locomotives on the various Railways. Four objects were particularly kept in view, namely, *safety*, *simplicity*, *accessibility* of the various parts, and *economy*, the whole combining general *efficacy* and *durability* of the engine throughout.

The first object is secured by giving a more extended *base* for the action of the springs in supporting the weight of the engine, being about six and a half by eleven feet, whereby a remarkably steady motion is secured at thirty miles per hour. It is not at all a matter of surprise that the four wheel engines of several Railways now in use should every now and then go off the road, and in an instant, when it is recollected the extreme base of their springs for supporting the engine is only about three three quarters by about six feet; hence their rocking, serpentine, and pitching motion, which without any other cause than a slight increase of speed, literally lifts the flanges of the wheels above the surface of the rails, and in three or four seconds the engine is turned end for end, upset in the act, and the train with it; whilst the stability of the engine is effectually secured through an extended base upon the front and hind wheels. By means of a new combination, the best properties of the four-wheeled engines are also completely applied, by resting the weight on the crank shaft immediately within the wheels, which experience has for years proved to be the place least likely to injure it, and thereby avoid the alarming accidents which have so often taken place by the breaking of the shaft, through placing the weight on bearings outside of the wheels; the centre of the engine being a sort of neutral axis, there is very little power over its motion in that part, and this advantage, by placing the weight on the crank inside the wheels, is, in consequence, got without a sacrifice of stability.

Secondly,—In addition to the safety and simplicity of having only *two* inner frames, instead of three or four, with as many bearings on the crank shaft, the space under the boiler is still further stripped of machinery by a new valve motion, which gives a high degree of openness and facility of access so desirable in examination, cleaning, &c, of the working parts.

Thirdly,—The steam being used expansively by the valve motion above alluded to, a great saving in fuel is effected, as will be seen on examining the results of the experiments, and as the excessive wear and tear of locomotive boilers arises from intense heat, it is not improbable this decided step towards removing the cause will prevent the effect, namely, the rapid destruction of the boiler. The action of this valve motion is perfectly smooth, being worked by eccentrics (which are also of an improved construction), and any quantity of steam from 25 to 90 per cent. on the stroke can be admitted into the cylinders with the most ready and complete control, at any speed the engine may be going; if a high wind or an incline oppose the progress of the engine, a greater quantity of steam is admitted; if wind or gradients be favourable, the steam is still admitted at full pressure into the cylinders, but shut off at an earlier period, propelling the pistons the remainder of the stroke by its elastic force, similar to driving a time-piece by the uncoiling of the main spring.

Lastly,—A combination of dimensions and proportions have been [illegible] from the best results of locomotive engines of various constructions, and in use in different parts of the country. The driving wheels are [illegible] length of the stroke 2 feet, diameter of cylinders 12 inches, [illegible] of fire-box, 2 by 3¼ feet, tubes, 94 in number, by 9¼ feet long, and [illegible] diameter. The general diminution of machinery in the construction has given room for ample dimensions in the principal working parts, and thus the whole arrangement has a close bearing on *safety*, *simplicity*, *accessibility*, and *economy*.

Todd, Railway Foundry, of this town. The Hull and Selby line was opened with the engines of the former order, but the public and the company being so much annoyed by hot cinders from their chimneys, burning whatever they lighted upon, and rapidly destroying the smoke boxes themselves, three of those engines were altered, and succeeded to a considerable extent in diminishing the nuisance, whilst the engines performed better, and with less fuel. That fact, however, being questioned, and two engines of the *improved* construction having got to work, Mr. John Gray, the engineer of the locomotive department, and patentee of the improved engines, urgently requested a most rigorous and simultaneous trial of the different engines, and to be witnessed for the parties concerned by persons above suspicion. Mr. J. Miller and Mr. T. Lindsley represented Messrs. Fenton, Murray, and Jackson; Mr. J. Craven and Mr. J. Barrons represented Messrs. Shepherd and Todd; and Messrs. E. Fletcher, W. B. Bray, J. G. Lynde, jun., J. Farnell, and J. Gray, were the representatives of the Hull and Selby Railway Company. The arrangements for the experiments were, that the gross load should include engine, tender, carriages, and every thing in the train.

The steam was got up in the respective engines to the pressure of from 56 to 66 lb. per square inch; the fires filled to a certain level at the starting in the morning, and filled to the same level on finishing the last trip at night. The pressure of steam at starting was generally up to 66 lb. and was at about half that pressure at the end of each trip. There were *fifty* experimental trips made in all, namely, twenty-four trips with the *Collingwood*, *Andrew Marvel*, and *Wellington*, the unaltered engines of Messrs. Fenton, Murray, and Jackson. Their average gross load was 53·4 tons, or 1656 tons, over one mile: consumption of coke 1013 lb. or 0·611 lb. per ton per mile; water, 6500 lb. or 3·90 lb. per ton per mile. There were ten trips made with the other three engines of Messrs. Fenton, Murray, and Jackson, which were altered at Hull, namely, the *Exley*, *Kingston*, and *Selby*. Their average load was 49·16 tons, or 1524 tons over one mile; consumption of coke, 635 lb. or 0·416 lb. per ton per mile: water, 4264 lb. or 2·79 lb. per ton per mile.

The *patent* engines made by Messrs. Shepherd and Todd, viz. the *Star* and *Vesta*, made sixteen trips, and their average loads, &c., were 55·4 tons, or 1718 tons over one mile; coke consumed, 465 lb. or 0·271 lb. per ton per mile; water, 2874 lb. or 1·62 lb. per ton per mile. The average gross load of all the fifty trips is 53·2 tons, or 1649·4 tons over one mile, and taking that as a standard load, the consumption of fuel and water performing exactly equal quantities of work, is represented in the following tables :—

Class of Engine.	Load in tons conveyed over one mile, in lbs.	Elsecar Coke used per trip of 31 miles, in lbs.	Coke used per mile, in lbs.	Coke used per ton per mile, in lbs.	Water used per trip of 31 miles, in lbs.	Water p er mile in lbs.	Water per ton per mile, in lbs.
Patent	1649·4	446·98	14·41	0·271	2672	86·19	1·62
Altered	1649·4	686·15	22·13	0·416	4601·6	148·43	2·79
Unaltered	1649·4	1007·78	32·59	0·611	6432·8	207·5	3·90

The financial annual result of the three classes of engines for coke and boilers, with such a traffic as that of the Hull and Selby line, will be about—

£4,500 for the unaltered engines.

£3,250 for the altered ditto; and about

£2,000 for the patent engines.

In conclusion, it is deserving of remark, that *all* the attesting witnesses expressed themselves highly satisfied with the manner in which the experiments had been conducted, and with the facilities which the Company so readily granted to enable them to come at correct results. Probably no experiments were ever made under similar circumstances where the parties concerned displayed greater independence, impartiality, and good feeling than on the present occasion.—*Leeds*

PATENT LAW.

An Important Case of Patent Law regarding the Amendment of Specification was heard in the Rolls' Court, on Friday, Nov. 6.

THE MATTER OF JOHN SHARP'S LETTERS PATENT.

The petition of Joshua Wordsworth, of Leeds, machine-maker, for expunging from the memorandum of alterations in the specification of Sharp's letters patent "for machinery for converting ropes into tow, &c.," such portions as were in substance descriptive of the same machinery as was invented by the petitioner Wordsworth, was resumed, and Mr. Bacon for Mr. Sharp followed Mr. Hill against the petition, and Mr. Pemberton, in behalf of Wordsworth, the petitioner, replied.

By statute 5 and 6 William IV., c. 73, "to amend the law touching letters patent for inventions," it is enacted "that any person having obtained letters patent for an invention may enter with the clerk of the patents (having first obtained the leave of the Attorney or Solicitor-General) a disclaimer of any part of his specification, or a memorandum of any alteration therein which is to be deemed part of such specification." Wordsworth's petition stated that letters patent were granted in October, 1836, to Sharp to make and vend his invention, part of which the petitioner stated was applicable to the preparing cotton wool and silk for spinning. The specification was enrolled in April, 1837. In May, 1838, letters patent were granted to the petitioner Wordsworth for an invention of improvements in machinery "for heckling and dressing flax, hemp, and other fibrous materials," and in November following the specification was enrolled. The petition then stated, that after this enrolment he (Wordsworth) discovered that Sharp had, in September, 1839, obtained from the Solicitor-General a certificate that Sharp had applied for leave to enter with the Clerk of the Patents certain memorandums of alterations of parts of his specification, and that the Solicitor-General had directed him to advertise the alterations, which was done; and, no objection having been made, the Solicitor-General granted leave to Sharp to file the memorandum of alterations, which alterations the petitioner stated were a new arrangement of machinery, and extended Sharp's patent to what were in substance his (Wordsworth's) inventions, as described in his specification. The petitioner submitted that the statute did not authorize the addition to a specification of any description of new machinery, and prayed for expunging the memorandum of alterations.

For the petition it was argued by Mr. Pemberton and Mr. James Russell, that the Master of the Rolls (in whose custody the rolls of the Court in Chancery were) had authority to permit alterations to be made in the rolls, and his jurisdiction for that purpose remained unimpeached by the act of William IV. The jurisdiction originally inherent in this court had been acted upon under the Municipal Corporation Act in question respecting the authority given to the Lords of the Treasury of interfering with the rolls of the court in the cases of "The Attorney-General against the Corporation of Liverpool," and against the Mayor of Poole, where it had been laid down by the Lord Chancellor, that to exclude the jurisdiction of one court there must be not only another tribunal created, but an absolute exclusion of all other authorities enacted. In a case of charitable trusts, which were to be exercised in such manner as the Lord Chancellor should direct, there was an appeal from the direction to the House of Lords, in which the question whether that house had jurisdiction was not decided, but the opinion expressed was that they had not. In "the Attorney-General against Norwich," the judges were unanimous against the jurisdiction of the house. To exclude the jurisdiction of this court there must be an express legislative exclusion; and the mere giving an authority to another tribunal would not have that effect. Where a clerical mistake was established that might be corrected. Every court had an entire control over its own records, as the Court of Common Pleas had over fines and recoveries; whether the error were clerical or otherwise, it made no difference, for the record was not in the state it ought to be. The rolls of this court were under the control of the Master of the Rolls, and the state in which the records ought to be was subject to his determination, which must control the opinion of the Solicitor-General. The memorandums of alterations were filed with the specification and became part of it. Had there been an alteration by erasure and substitution of other words, a difficulty would have been created; but there was no difficulty here in ordering the memorandum to be taken off the rolls. The act had not given the Solicitor-General power to decide conclusively and without appeal what should or should not be on the rolls, nor had it excluded the jurisdiction of the judges of the court over its rolls. Suppose *per incuriam* or by mistake in his clerk a fiat for an inconsiderate alteration had been given, or suppose the fiat had been attached to a wrong memorandum, the Solicitor-General would have no authority after he had given his fiat to correct any mistake or fraud, nor would there be any means of making such correction if the jurisdiction of this Court were taken away. The effect of the fiat was merely that certain things should be placed upon the record, subject in all respects to the same conditions as the other records were. If the memorandum were not warranted, the Court could take it off. Had the statute made the fiat absolute, that could not have been done, but the fiat left the jurisdiction precisely in the same state it was in before, and it was for his Lordship to determine whether the memorandum of alterations ought or ought not to remain a record of the Court, and if not, his Lordship had jurisdiction to order it to be removed. He did not contend that his Lordship could order a patent to be taken off the rolls of the court on the ground that the invention was not new, but whether his Lordship was to decide whether such circumstances had existed as could justify the memorandum being put upon the rolls. The question was not to be determined by the law officers of the Crown without the control of any other authority. The act had not declared their fiat conclusive, nor had it extended any right given by the letters patent. The Legislature prevented the record being altered at the mere will of the parties, enacting that there must be the leave of the Attorney or Solicitor-General. Their fiat was not to extend the exclusive right granted by the letters patent, but this fiat extended those rights; therefore the memorandum of alteration was not such as the act allowed, and if so, the fiat was good for nothing. It might be said, that if the memorandum is not warranted by the act, the objection might be taken in an action at law; but the answer to that would be, that the alteration is incorporated into the letters patent, and alters the specification; and although the petitioner in an action at law might say the invention as specified in the alteration was neither new nor useful, he could not say it was no part of the specification, and he might have a right to have his action tried upon the original specification. If the fiat were conclusive, the alterations could not be severed [illegible] the record, for the statute had made them part of the record so long as the fiat remained. Unless the court had jurisdiction, the fiat would, in altering the records of the Court, be conclusive not only against the Court, but against the Attorney and Solicitor-General themselves, for the act had not provided a mode of amending any mistakes they might have been led into. Where surreptitious or forged documents were discovered to be placed upon the rolls of the court, it would be no answer to an application for their removal to say that an action could not be brought upon them. The Court would order an invalid instrument to be delivered up, on the ground that it formed a cloud upon the title of the individual whose interest was sought to be affected by it.

Mr. Hill and Mr. Bacon, for Mr. Sharp, against the petition, said the arguments for the petition were, that the specification with the alteration was a record of the court, that such records might be amended by his Lordship, that the prayer was in substance for an amendment, and that the petitioner had that interest in the question which authorized him to make the application. The specification with the alterations might for many purposes be a record, but under the colour of that general term inferences not quite sound had been drawn. The patent was granted upon a proviso that the patentee should at a certain time enrol a specification; but that proviso did not give the specification any of those high attributes of records which had been claimed for it. A record imported verity, and if the petitioner's argument was well-founded, no person could defend an action in which the patentee could prove an infringement of his patent. But from the statute of James I. these records had been treated only as the statement of a party who was bound to prove every averment he made, as that there was an invention, that he was the first inventor, &c. The patentee could not hold up his specification, and say "Here is a record, you are estopped from saying I am not the first inventor; my case was determined before we came into court." Nothing of that sort could be said. The specification was not a record in the sense and for the purposes for which that word had been used, nor was the memorandum incorporated in the specification such a record. In one of the cases cited (Redmond's) there was a clerical error, and that which had been intended was not done. If that had been the case here, his Lordship might, but with considerable trepidation, go back and bring the intention and the act which had parted company into agreement again; but his Lordship had been required to erect the Court into a court of appeal over judgment of the Solicitor-General, and to do what that officer might have done had he viewed the matter in a different light. Such a procedure would not come within the doctrine of amendments. It might as well be said that the reversal by writ of error of a judgment at common law was an amendment of the record; it was confounding things entirely different; it was not an amendment of the record, but the correction of the errors of an inferior court. In analogy to the practice of the common law, there must be something to amend by. The present was not a question of amendment. Before the statute of William IV. there was no authority that could enable a patentee to disclaim any part of his patent; it was a new power given to the Crown, and vested in its legal officers. By the common law the Crown had great powers in granting monopolies, which by the statute of James were restricted to new inventions, and to the term of 14 years, and where the patentee by his specification had made his claim too large, it was fatal to his patent; but the late act had given the Attorney-General power to permit the patentee to disclaim a portion of his patent. When a power was created by the Legislature and vested in a certain tribunal, then no other court had jurisdiction. The invention was only one condition—the inventor must have a patent and specification. The memorandum remaining on the files of the Court decided nothing but that the memorandum was authentic; it did not decide that there was an invention, or that the patentee was the inventor. The alleged invention might not be new, but that would be no reason for taking the memorandum off the files of the court. A bill in equity was not taken off the files of the court because it contained false allegations. If a judgment were erroneous, it would be a reason to appeal from it, but no reason to take it off the rolls of the court. The difference was between what was genuine and what was authentic. He did not argue that all was necessarily genuine, but he did say it was all authentic, and the question was to try the authenticity. The argument for the petition went to change the whole course of proceedings in patents from the time of James I., and he would advise his friend, who was the inventor of the doctrine, to get a patent for it. Whether it would stand as a new machinery for trying the validity of patents by their specification before the Master of the Rolls, would be a question. It was said that whatever had any vice would be taken off the rolls of the court, which would not bear anything on its rolls which contained an erroneous allegation. The question was, who was the new inventor? An issue could not be granted to determine the question of amendment. The Solicitor-General required advertisements to be made of the application to him, and gave it two hearings; so that the fiat for filing the memorandum of alterations was not granted in haste, but after due consideration. The validity of patents ought not to be decided in the present mode of proceeding. The mode of trying those questions had been settled for years, and ought not to be altered.

Mr. Pemberton replied. As long as the memorandum of the alterations with the fiat of the Solicitor-General remained as part of the rolls of the court, it would not be competent for any person to deny that the memorandum was a part of the specification on which the patent was granted. The statute did not authorize the memorandum to be placed on the rolls, for the memorandum did not form part of the specification. He would ask, had the

that his Lordship had no power to interfere would be good; but if the memorandum were improperly placed, then it formed no part of the grant, and his Lordship would remove it from the record, as he would remove a forged specification or correct a clerical error.

Lord Langdale said, it was his duty to receive the records of the court, and in his character of recipient he had no doubt of his jurisdiction. He was to receive such documents as parties presented as the records of their own acts. If it were shown that documents had been presented which were not an accurate record, it would be his care to discover where the error arose, and to satisfy himself that it was an error. He would see what had been done upon former occasions.

Mr. Pemberton.—The question was not whether his Lordship could alter a record, but whether the enrolment as it stood was a record.

NEW INVENTIONS AND IMPROVEMENTS.

An improved method of retarding and stopping railway trains; patented by Henry Montague Grover, of Boveney, Buckingham, Nov. 7.—Claim first.—The application of electro or other magnetism for the purpose of retarding or stopping railway trains—A magnet, of the ordinary horse-shoe form, is let into a block of wood, and fixed by sustaining rods in such a position that its ends are a short distance from the face of the tire of one of the wheels. A galvanic battery is placed on the bed or platform of the carriage, and a connection of the magnet and the face of the tire of the wheel formed when necessary, by means of connecting wires, which will cause the wheel to be retarded or stopped. These magnets may be applied to any number of wheels in this manner, or through one magnet to a lever, and by cranks or other apparatus, indirectly to the wheels.—*Inventors' Advocate.*

An improved apparatus or process for producing sculptured forms, figures, and devices, in marble and other hard substances; patented by William Newton, of Chancery-lane, Middlesex, (being a communication from a foreigner residing abroad), Oct. 22.—These improvements consist, first, in the construction of a mould, die, or matrice, of metal or other hard substance, in which the counterform of the figure or device intended to be sculptured has been made, and its application to the stone or marble intended to be cut.—Secondly, in the means by which the sculpturing is effected; viz., by the repetition of slight but rapid blows of the mould, or die, struck against the face of the stone, by which the surface becomes abraded, and particles are gradually broken off, leaving the stone ultimately in a form, or figure, corresponding to the mould or die which has been working upon it.—Claim.—Application of a mould or striking die, which being by any arrangement made to strike a rapid succession of light blows on the substance to be sculptured, shall abrade or wear away the superfluous parts of the surface of the material under operation, and produce a form, or figure, corresponding with the mould or die.—The mould must be mounted in any convenient mechanical apparatus capable of holding, raising, and depressing it, that it may strike very light but rapid blows on the face of the block to be sculptured, which must be supported upon firm stationary bearings; the mould or die is securely attached to a lever, which is a strong frame of iron, mounted on pivots, which are made adjustable, in order to regulate the height of the frame, from the block of marble or stone; to the outer end of the lever a staple also adjustable by a screw and nut is fixed, to which is attached a cord, also connected to a series of cranks and rods, which are mounted in a horse-shaped frame: a crank in the lower end of this series is acted upon by stops, notches, or teeth, in the periphery of a tappet or rachet wheel, which is acted on by a pulley being made to revolve on its axis driven by a band from any first mover; so that on a rotary motion of the tappet wheel, its teeth will act against the arm of the lower crank, and produce a slight reciprocating motion in the series of cranks and rods, which will be communicated through the cord to the lever which holds the mould, thereby causing a rapid succession of slight blows to bear upon the surface of the block, and in a short time to abrade all those parts of the stone against which the mould or die strikes. The process will be facilitated by the introduction of sand, emery, or diamond dust, with water, at an early stage of the work, and may be introduced by a simple inclined plane, or in any convenient manner; towards the end of the process a finer powder should be used, and the work will leave the mould in a highly-finished state. This invention applies to busts, statues, and groups of figures, even the most complicated and extensive, and finishes them with the greatest delicacy, only it is necessary to employ several small moulds instead of one, and it will act equally well on crumbling stone, that would not bear the chisel, as upon a solid mass.—The inventor claims no particular arrangement of apparatus for causing the mould to strike the face of the block, although he considers that above described suitable and appropriate for the purpose.—*Ibid.*

A composition for the prevention of corrosion in metals, and for other purposes; patented by Arthur Wall, of Bermondsey, surgeon, October 15, 1840.—This composition is prepared in the following manner:—20 lb. of strong muriatic acid are diluted with 3 gallons of water and placed in a shallow cast iron vessel; 112 lb. of steel or iron filings are heated to redness and quenched in the diluted acid to effect their oxidation; to facilitate this action, the pan is placed on a furnace or sand-bath, and the contents repeatedly stirred for about 24 hours, or until ebullition takes place, the liquor is then drawn off, and the foregoing process repeated with such portion of the filings as remain unoxidized. The oxide thus obtained is exposed on a red hot iron plate, till all the moisture has been driven off, and the oxide assumes a red appearance When cold, 16lb. of quicksilver are to be added to the mixture, by sifting through a fine sieve, and afterwards intimately incorporated in a mortar; enough water to cover the surface is then poured over it, and from 8 to 9 lb. of strong nitric or nitrous acid added; this mixture is to be placed in a sand-bath till all the moisture is driven off. When the mass is dry it is to be well pounded in a mortar till it assumes a uniform state of blackness. All the particles are to be separated by washing in water, and left to settle; the ——— to be placed in a crucible or earthen retort, with a receiver attached to collect any chloride or mercury that may come over. When red hot plunge it into fresh boiling water, stir it well and leave it to settle, then draw off the water and add any chloride that may have come over into the receiver. Then add one-fourth of its weight of common black or red lead, according to the colour desired. This composition is to be mixed with boiled linseed oil with one fifth of spirits of turpentine, and applied as thinly ——s with a brush to the sheets of metal to be protected. The me— in this manner is to be dried by the application of heat, beginning with a low temperature, and gradually raised to about 300° of Fahrenheit, so as to make the metal "*imbibe*" the preparation. The claim is, for the invention of the composition prepared as above described, for the prevention of corrosion in metals, and for other purposes.—*Mech. Mag.*

STEAM NAVIGATION.

The Clyde.—There was launched, on the 27th October last, at Clyde Bank a new steam dredging vessel for the River Clyde trustees. This vessel is the largest of the kind which has yet been built on the Clyde; she is 100 feet long and 22 feet broad; she is to carry an engine of 24 horse power, and to work effectively in 18 feet depth of water. The engine for this vessel has been constructed by Mr. John Nelson, of Oak Bank Foundry, in accordance with the specification drawn up by Mr. Bald, engineer of the Clyde. This vessel is now in the harbour of the Broomielaw, for the purpose of receiving the engine and machinery on board. A very beautiful model of this vessel, on a scale of one foot to an inch, was exhibited in the model room of the British Association, and which was constructed under the direction of Mr. Bald, before the steam dredge-boat was built.

—vigation of the Mersey.—The *Warrington*, a new iron steamer, of 200 tons —en, builder's measurement, built entirely (engines and hull) by the Warrington Bridge Foundry Company, made her first experimental trip down the Mersey to Liverpool and back on Wednesday, 11th ult. On her downward voyage she sailed remarkably well, and took in tow several flats bound for Liverpool. On her return home, she steamed from the Old Quay Pier, —ol, to the Old Quay, at Runcorn, in one hour and twenty-two minutes, towing one of Messrs. John Hodson and Company's flats. From Runcorn to Warrington, a distance of ten miles and a half, her speed was put to the test. In spite of a heavy fresh, and the disadvantage of getting up her speed after stopping at Runcorn, she completed the distance in forty-seven minutes. As far as the navigation of the Mersey is concerned, all difficulties thrown in the way of Warrington one day becoming a bonded port have now been made to disappear.—*Liverpool Times.*

The Mammoth Iron Steamer at Bristol.—A gentleman who has recently seen the immense iron steamer building by the Great Western Steam Ship Company at Bristol, informs us that she will *register* about 3,000 tons, but that her actual tonnage will exceed 3,600 tons, or about 600 tons more than any ship ever built. An immense saving in stowage will be gained in consequence of the adoption of iron for her hull, whilst her draught of water will be comparatively small, owing to the great buoyancy possessed by iron vessels. She will consequently be able to carry coals sufficient both for her outward and homeward passages,—a most important point, when the inferior quality of coals obtainable in America, and consequent diminution in speed, is considered. Her engines, we hear, are to be of 1000 horse power, and it is confidently expected that the average voyage across the Atlantic will be reduced to ten days. She will carry a vast spread of canvass, so that in all probability the engines will frequently be at rest. In consequence of the adoption of Smith's Screw Propeller, this stupendous ship, the greatest experiment in steam navigation ever made, will, we believe, be able to pass the present locks at Cumberland Basin, and discharge her cargo in Bristol Harbour. We congratulate our Bristol neighbours upon the enterprise which they are displaying. Two magnificent steamers are now building at Bristol, by Messrs. Acraman, for the Royal Mail Company; and, altogether, the ancient port seems to be "going a-head."—*Gloucester Chronicle.*

Iron Steamer.—On Saturday the 21st ult., was launched from Messrs. Ditchburn and Mare's building yard, at Blackwall, a wrought iron steam vessel of 160 tons, named the "Mermaid," to be propelled by an engine on an entirely new principle, of 50 horse power, invented expressly to drive the Archimedes screw without the aid of geering-wheels. Should its power equal its simplicity, it is likely to cause a change in steam engines. The engine is making by Messrs. Rennie's.

—vention of Steam Packet Collisions.—The Corporation of the Trinity —e has deemed it right to frame and promulgate the following rules, —ch, on communication with the Lords Commissioners of the Admiralty, the Elder Brethren find have been already adopted in respect of steam-vessels in Her Majesty's service." Rule first—"When steam-vessels on different courses must unavoidably or necessarily cross so near that by continuing their respective courses there would be a risk of coming into collision, each vessel shall put her "helm to port," so as always to pass on the larboard side of each other." Rule second—"A steam vessel passing another in a narrow channel must always leave the vessel she is passing on the l—rboard hand."

Steamers Wanted.—We had hoped that the cry of "steamers wanted" which we have continually kept up for the last two years, would before this have been responded to by the arrival of steamers from England; but as we see that the subject was alluded to in several London and Liverpool papers of November and December last, we still hope that many months will not elapse before several steamers arrive in the colony. The following steamers — now urgently wanted — ——e steam-boats to run from Port Philip to Sydney; Sydney to New Zealand; a second to be added in a —— months; three boats to run to Hunter's River; a boat to run to —— River; a boat to run to Brisbane Water; a couple of small boats to run between Newcastle and the different towns on the Hunter, Williams, and Paterson. Besides the above, a boat will be required to run to Twofold Bay very shortly, as the country between there and Manaroe, called the Bija is beginning to attract attention; boats for Jervis's and Bateman's —— soon be required. We consider the above boats are requ—— ——tion to those now here, for there will always be some of the vessels meeting with accidents, and otherwise requiring repair, and it is of the greatest importance that boats should run regularly. Although the above are urgently required, we believe that the only boats that can be depended upon, as sure to arrive during the present year, are two for the Hunter's River Company, and one for Port Philip. Half a dozen vessels of different burdens sent to this colony would be a splendid speculation.—*Sydney Herald*, May 15.

—— OF ——

—— now 2,270 miles of railroads completed, or nearly completed, in the United States, besides 2,346 miles of railroads in progress of construction, making a total (when finished) of 4,616 miles.—*Times.*

Greenwich Railway.—Tenders as delivered on Tuesday, 3rd November, for widening the Greenwich Railway, from the Croydon Junction to Tooley Street, (extending *nearly a mile* for the present contract.)

Mr. Jackson	£34,900
Messrs. Grissell and Peto	37,791
Messrs. Baker & Son	38,734
Messrs. Little & Son	38,900
Mr. Lee	38,850
Messrs. Piper & Son	39,300
Mr. Bennett	39,972
Messrs. Ward	43,320
Mr. M'Intosh	43,500
Mr.	46,596

Taff Vale Railway.—We are glad to perceive that the promoters of the prosperity of this town, are not unmindful of the inducements which its great natural advantages hold out for the accomplishment of railway communication with other districts of the kingdom, as well as the importance of meeting other places in the race of competition by the aid of this grand achievement of modern science. The progressive commercial importance, and the exhaustless mineral wealth of Newport and its neighbourhood, have been so frequently the theme of observation in this journal, that it would be superfluous at present to dwell on facts, admitted by all, as incentives to action during the railway undertakings now completed or in course of operation through the leading districts of the kingdom. Our position is commanding, our advantages great, and our exertions should be commensurate to obtain a participation in the benefits for our town and port, and for the county at large, that railway communication with the great arteries of the traffic of the kingdom, is now diffusing. A railway is projected between Newport and Gloucester, taking the circuit of Monmouth and Usk. We understand that Mr. Barber, late of the Taff Vale Railway, a —— highly spoken of as possessing great talents in his profession, is directing his best energies to the subject, and with the support he has already received, we augur well for the maturity of his plans. The question shall be —— in our columns.—*Monmouthshire Merlin.*

South-Eastern Railway.—This great undertaking is now proceedi—— the utmost vigour; all the works between Tunbridge and Redhill are in a state of great forwardne—s, it being the intention of the directors to open —— line as far as Tunbridge, with the least possible delay. The tunnel, near t—— village of Bletchingly, which is a particularly arduous and heavy structure, is also progressing considerably. This is one of the most interesting works upon the line, particularly to the geologist, as it passes under ground near the foot of Tilburston-hill, which it is well known has been subjected to some powerful subterraneous action, the strata upon some parts of the hill being singularly distorted. All the phenomena observed by the engineer in the progress of the work shows this spot to have been peculiarly subjected to the upheaving and disturbing powers which, at some remote period, have been in active operation. Mr. Simms, the engineer, who resides at Bletchingly, is in possession of several interesting fossils, which he has found in —— of his ——

—— *Railway.*—Agreeably to our promise, we this week recur to the subject of a railway from Newport to Gloucester. It appears that two lines have been surveyed, the one by Usk and —— other by Chepstow and Newnham; and it is a matter of the —— to arrive at a sound conclusion, as to which line will best subserve the —terests of the public, and of the districts through which it passes. We —— —— long impressed with the importance, and indeed, the necessity for, a railway communication through this rich and greatly improving districts; and having attentively considered the subject, it appears that there can be but one opinion as to the eligibility of the central line, and of the impolicy of allowing a trifling difference offset, to weigh in the consideration of a question —— results of such paramount advantage. The line —— follow the banks of the Severn, —— ——n, and with a —— along the opposite bank, that we think it —— line embracing towns of importance, and laying open a splendid district —— country, greatly needing the facilities of —— the traffic from the important districts of Pont—— ——n, &c., largely flow into the line near Usk, and the —— would doubtless communicate —— Ross. The central —— affords a guarantee that traffic will be derived way. We have had the pleasure of inspecting the plans of the line surveyed by Mr. Barber, and as our readers feel great interest in the subject, we will endeavour to obtain the details of its course.—*Bristol Paper.*

Proving Steam-Engine Boilers in Belgium.—By a decree of King Leopold, dated Oct. 28, it is ordained :—"That every boiler in which the steam is required to have a pressure of more th n one atmosphere shall be submitted to a proof of treple the force it will be required to support. This pressure to be determined by the difference between the authorised pressure of the steam in the boiler and atmospheric pressure.—Considering that tabular boilers of locomotive engines may safely be exposed to less rigorous proof, on the report of our Minister of the Public Works, we have decreed,—Article 1. That the boilers of locomotive engines intended to run on railroads shall be submitted to a proof of twice the amount those engines are required to support.—Art. 2. The permission to make use of locomotives belonging to the state will be ——ted after the trials prescribed by the articles of the first and second de-___ by the director of the rai'roads now in operation.—Art. 3. The proof of the locomotive engines shall be renewed at least once a year; they shall take place after every important repair of the boiler. The boilers that are injured during the proof shall not be used.—Art. 4. The director of the railroads in operation shall address to our Minister of the Public Works a duplicate of the permission to use the engines, and of the declarations of proof."

Haven Dock and Railway.—Considerable exertions are being made for pushing forward this important undertaking in the ensuing spring.

MISCELLANEA.

Mast Conveying.—It has been usual of late, since it has been considered objectionable to immerse made masts in the water, to send them from the mast-houses on trucks, a process which does them no good, and occupies a whole day when a line-of-battle ship's lower mast is to be dealt with. A method, however, was tried on Tuesday last with the Indus's foremast, and it answered admirably, to convey it by water, without wetting it, in the following way:—Two flat-bottomed boats, placed side by side, and having strong skids laid [illegible] their gunwales, were brought to the slipway, at the back of the mast-[illegible]s, and properly placed; the mast was then launched out until it pro-[illegible] beyond the boats, and over the centre of the skids until its heel end [illegible] upon them; the launching of the mast was then continued, the boats bearing it, and another pair of flat-bottomed boats, similarly fitted with skids, [illegible] brought and placed under the mast towards its head, which, as it des-[illegible]ed the slip, presently rested on them, as the heel had done before, upon the skids of the boats first placed; the tressel trees were then bolted on, and the flats with their burden were towed away to the sheers, where the Indus was waiting for, and very soon received, her foremast, which had thus been conveyed perfectly dry. This novel operation was carried into effect under the superintendence of the officers of the mast-house; for the idea, however, and also the details of the scheme, the service is indebted to Mr. Whettem, an intelligent and zealous inspector in the mast-making department.—*Times, Nov. 2.*

A steam fire-engine has been invented at New York, by Captain Erichsen. It weighs only $2\frac{1}{2}$ tons, and will throw 3,000 pounds of water per minute to a height of 105 feet, through a nozzle of $1\frac{1}{4}$ inch diameter.—*Times.*

Wire Rope for Standing Rigging.—Last week a series of trials of Smith's Patent Wire Rope was made at the Corporation testing-machine, in Trentham Street, Liverpool, in presence of a number of nautical gentlemen and others interested in improvements in navigation, and the result was highly satisfactory. The patent consists of improved methods of forming a [illegible] from any number of wires that shall be flexible, is served with hemp, and can also be spliced or knotted. The rope is tarred in the usual way as to exclude the water; and a chemical preparation is employed to prevent oxidation. The rigging with wire rope is smaller and lighter than of hempen rope, and as it offers much less resistance to the wind, is of great advantage in beating to windward. The cost, too, is much less, and the durability [illegible] In the trials we have alluded to, the following results were ascer-[illegible]

1-inch rope broke at 2 tons 1 cwt.
[illegible] 5 .. 0 ..
[illegible] 8 .. 14 ..

[illegible] were also tried with proportionate success; and it should be remarked, that a *three inch* hempen rope of the best quality broke at 2 tons 1 cwt. The weight or traction borne by each piece of different sized rope far exceeded that fixed in the scale of the patentee, thus showing great superiority in the workmanship of the manufacturers, Messrs. Fox and Co. of London and Birmingham. According to the scale alluded to, the weight to be sustained by $1\frac{1}{4}$ inch wire rope is 3 tons 10 cwt., and so in proportion. Another good quality of the wire rope is its elas icity, which, though not of [illegible] rope, is quite sufficient to counteract the effects [illegible]l is rolling heavily at sea. One comparatively [illegible] was tried, stretched $18\frac{1}{2}$ inches before it broke. A short length of $1\frac{1}{4}$ inch stretched 6 inches. The machine on which the [illegible] is very ingenious, and of tremendous multiplying power; it is that on which iron cables for the largest ships are put to their utmost tension of many tons. The gentlemen present took a deep interest in the operations, and were at once gratified and astonished to witness the immense weight or traction sustained by lengths of wire rope so comparatively small and light. It should be added, that this patent rigging has been test[illegible] upwards of five years, and that amongst the ships fitted with it in our own port are those crack steamers the *Oriental* and the *Liverpool*. The new light ship, the *Albert*, destined for the Victoria Channel, is also rigged with it, and it has hitherto been highly approved by practical men.—*Liverpool Standard.*

Survey of the Northern Counties of England.—We have much satisfaction in conveying the gratifying intelligence that the secretary of the Manchester Geological Society has received a communication from the Lords of the Treasury, announcing their intention to co duct the survey of the six northern counties of England, on an enlarged scale of six inches to the mile, instead of two inches, the size adopted for the other counties, and that they are to commence with Lancashire forthwith. This is a matter of very great importance to the landed interest, as well as to the proprietors of mines, coal mines, and quarries, and hence to the community at large, in this thickly peopled district. For this important improvement in the survey, we are indebted to the exertions of the Geological Society of Manchester, with whom the idea originated. They memorialised the Treasury, and influenced other scientific societies to follow their example, and thus paved the way to this important result. This fact alone proves the high importance of the Geological Society, seeing that their first acts are directed to the prosperity of the county and its varied mercantile interests. It is, therefore, the duty of the gentlemen of this and the surrounding towns to become members of this society, and by increasing its funds enable it to pursue its useful and laudable exertions with increased vigour.—*Manchester Chronicle.*

Ancient Window.—An ancient stained glass window of the 15th century, which formerly belonged to a convent at Mechlin, has just been placed in the church of St. George's, Hanover Squa[illegible]

Improvement of the Severn.—The *Bristol Journal* has the following remarks upon the proposed improvement of the navigation of the river Severn:—"In the trading interests of Bristol, this long-wanted improvement must be of the greatest advantage in developing and carrying out those vast enterprizes which our fellow citizens have of late projected with such laudable spirit and liberality; thereby securing to them the readiest and cheapest conveyance of the vast mineral products and the produce of the potteries of Staffordshire, the salt of Droitwich, and the various manufactures of Birmingham and its neighbourhood, through the Worcester and Birmingham canal; nor will the port of Gloucester, and more particularly those of Newport and Cardiff, in South Wales, be less benefitted. In the present migratory state of commerce and manufactures, with competition every where taking place, and in which the minutest fraction in cheapness and certainty of conveyance will turn the scale, we do consider the contemplated improvement of first-rate advantage to Bristol. The great wonder is, that such an anomalous state of things, in these days of commercial enterprise, should so long have been suffered to exist."

LIST OF NEW PATENTS.

GRANTED IN ENGLAND FROM 2ND NOVEMBER TO 25TH NOVEMBER, 1840.

John Duncan, of Great George Street, Westminster, Gentleman, for "*improvements in machinery for cutting, reaping, or severing grass, grain, corn, or other like growing plants or herbs.*" Communicated by a foreigner residing abroad.—Sealed November 2; six months for enrolment.

Elijah Galloway, of Manchester Street, Engineer, for "*improvements in propelling railroad carriages.*"—November 2; six months.

Josiah Humphrey, of New Tower Row, Birmingham, Brass Founder, for "*certain improvements in machinery to be employed in the manufacture of wire hooks and eyes.*"—November 2; six months.

Henry Wimshurst, of Limehouse, Ship Builder, for "*improvements in [illegible], in communicating power to propellers of steam vessels, and unshipping propellers.*"—November 2; six months.

James Heywood Whitehead, of Royal George Mills, York, Manufacturer, for "*improvements in the manufacture of woollen belts, bands, or driving straps.*"—November 2; six months.

James Boydell, junior, of Cheltenham, for "*improvements in working railway and other carriages, in order to stop them, and also to prevent their running off the rails.*"—November 2; six months.

John Edward Orange, of Lincoln's Inn Old Square, Captain in the 61st Regiment, for "*improvements in apparatus for serving ropes and cables with yarn.*"—November 2; six months.

Herman Schroeder, of Surrey Cottage, Peckham, Broker, for "*improvements in filters.*" Communicated by a foreigner residing abroad.—November 2; six months.

John Wordsworth Robson, of Wellclose Square, Artist, for "*certain improvements in water closets.*"—November 2; six months.

Richard Farger Emmerson, of Walworth, Gentleman, for "*improve-[illegible] in applying a coating to the surfaces of iron pipes and [illegible]*"—November 3; six months.

[illegible] Rapson, of Limehouse, Millwright, for "*improvements in paddle-wheels for propelling vessels by steam or other power.*"—November 3; six months.

Henry Hind Edwards, of Nottingham Terrace, New Road, Engineer, for "*improvements in evaporation.*"—November 5; six months.

Mathew Mankoury, of Leicester Square, Gentleman, for "*im-[illegible] wind and stringed musical instruments.*" Communicated by a foreigner residing abroad.—November 5; six months.

George Gwynne, of Duke Street, Manchester Square, Gentleman, for "*improvements in the manufacture of candles, and in t[illegible] and fats.*"—November 5; six months.

George Dacres Paterson, of Truro, Esquire, for "*improvements in curvilinear turning, (that is to say) a rest adapted for cutting out*

...els, and a self-acting side rest for other kinds of curvilinear turnings."—November 5; six months.

Henry Kirk, of Blackheath, Gentleman, for "*improvements in the application of a substance or composition as a substitute for ice for skating and sliding purposes.*"—November 5; six months.

Charles Joseph Hullmandel, Great Marlborough Street, Lithographic Printer, for "*a new effect of light and shadow, imitating a brush or stump drawing or both combined, produced on paper, being an impression from a plate or stone prepared in a particular manner for that purpose, as also the mode of preparing the said plate or stone for that object.*"—November 5; four months.

John Clarke, of Islington, Lancaster, Plumber and Glazier, for "*an hydraulic double action force and lift-pump.*" Communicated by a foreigner residing abroad.—November 5; six months.

George Delianson Clark, of the Strand, Gentleman, for "*an improvement in purifying tallow fats and oils for various uses, by purifying them and depriving them of offensive smells, and solidifying such as are fluid, and giving additional hardness and solidity to such as are solid, and also by a new process of separating stearine or stearic-acid from the elanie in such substances.*" Communicated by a foreigner residing abroad.—November 5; six months.

Alexander Horatio Simpson, of New Palace Yard, Westminster, Gentleman, for "*a machine or apparatus to be used as a movable observatory or telegraph, and as a movable platform in erecting, repairing, painting, or cleaning the interior and exterior of buildings, and also as a fire-escape.*" Communicated by a foreigner residing abroad."—November 5; six months.

Andrew Kurtz, of Liverpool, Manufacturing Chemist, for "*a certain improvement or certain improvements in the construction of furnaces.*"—November 5; six months.

George Halpin, junior, of Dublin, Civil Engineer, for "*improvements in applying air to lamps.*"—November 7; six months.

William Crofts, of New Radford, Nottingham, Machine Maker, for "*certain improvements in machinery, for the purpose of making figured or ornamental bobbin-net or twist-lace, and other ornamental fabrics looped or woven.*"—November 7; six months.

Charles de Bergue, of Blackheath, Gentleman, for "*improvements in machinery for making reeds used in weaving*" Communicated to him by a foreigner residing abroad.—November 7; six months.

Edward Dodd, of Kentish Town, Musical Instrument Maker, for "*improvements in piano-fortes.*"—November 7; six months.

George Edward Donisthorpe, of Leicester, Machine Maker, for "*certain improvements in machinery or apparatus for combining and preparing wool, and other textile substances.*"—November 7; six months.

John Joseph Mechi, of Leadenhall Street, Cutler, for "*improvements in apparatus to be applied to lamps, in order to carry off heat and the products of combustion.*"—November 10; two months.

Thomas Lawes, of Canal Bridge, Old Kent Road, Feather Factor, for "*certain improvements in the method or process, and apparatus for cleansing and dressing feathers.*"—November 10; six months.

William M'Kinley, of Manchester, Engraver, for "*certain improvements in machinery or apparatus for measuring, folding, plaiting, or lapping goods or fabrics.*"—November 10; six months.

Charles Edwards Amos, of Great Guilford Street, Millwright, for "*certain improvements in the manufacture of paper.*"—November 10; six months.

Thomas William Parkin, and Elisha Wille, of Portland Street, Liverpool, Engineers, for "*an improved method of making and working locomotive and other steam-engines.*"—November 12; two months.

Eugenius Birch, of Cannon Row, Westminster, Civil Engineer, for "*improvements applicable to railroads, and to the engines and carriages to be worked thereon.*"—November 12; six months.

John Heaton, of Preston, Overlooker, for "*improvements in dressing yarns of linen, or cotton, or both, to be woven into various sorts of cloth.*"—November 12; six months.

Otto C. Von Almonde, of Threadneedle Street, Merchant, for "*improvements in the production of Mosaic work from wood.*" Communicated by a foreigner residing abroad.—November 12; six months.

Charles Dod, of Buckingham Street, Adelphi, Gentleman, for "*certain methods or processes for the manufacture of plate-glass, and also of substances in imitation of marbles, stones, agates, and other minerals, of all forms and dimensions, applicable to objects both of use and ornament.*" Communicated by a foreigner residing abroad.—November 12; two months.

Charles Wye Williams, of Liverpool, Civil Engineer, for "*certain improvements in the construction of furnaces and boilers.*"—November 17; six months.

Joshua Shaw, of Goswell Street Road, Artist, for "*certain improvements in discharging ordnance, muskets, fowling-pieces, and other fire-arms.*"—November 17; six months.

Joseph Whitworth, of Manchester, Engineer, and John Spear, of the same place, Gentleman, for "*certain improvements in machinery, tools, or apparatus for cutting and shaping metals and other substances.*"—November 17; six months.

James Deacon, of Saint John Street Road, Gentleman, for "*improvements in the manufacture of glass chimneys for lamps.*"—November 19; six months.

Alexander Stevens, of Manchester, Engineer, for "*certain improvements in machinery or apparatus to be used as an universal chuck for turning and boring purposes, which said improvements are also applicable to other useful purposes.*"—November 19; six months.

William Henson, of Allen Street, Lambeth, Engineer, for "*improvements in machinery for making or producing certain fabrics with threads or yarns applicable to various useful purposes.*"—November 19; six months.

John Cox, of Ironmonger Lane, Civil Engineer, for "*certain improvements in the construction of ovens applicable to the manufacture of coke, and other purposes.*"—November 21; two months.

John Wakefield, of Salford, Hat Manufacturer, and John Ashton, of Manchester, Hat Manufacturer, for "*certain improvements in the manufacture of hat bodies.*"—November 21; six months.

William Henry Hutchins, of Whitechapel Road, Gentleman, and Joseph Bakewell, of Brixton, Civil Engineer, for "*improvements in preventing ships and other vessels from foundering, and also for raising vessels when sunk.*"—November 21; six months.

Francis Pope, of Wolverhampton, Engineer, for "*improvements in detaching locomotive and other carriages.*"—November 24; six months.

John Haughton, of Liverpool, Clerk, M. A., for "*improvements in the means employed in railway accidents resulting from one train overtaking another.*"—November 24; six months.

Henry Charles Danberry, residing at Boulogne, Esquire, for "*an improvement in the making and forming of paddle-wheels for the use of vessels propelled on the water by steam or other power, and applicable to propel vessels and mills.*"—November 25; six months.

Thomas Barratt, of Somerset, for "*improvements in the manufacture of paper.*"—November 25; six months.

Junius Smith, of Fen Court, Fenchurch Street, Esquire, for "*certain improvements in furnaces.*" Communicated by a foreigner residing abroad.—November 25; six months.

Charles Grellett, of Hatton Garden, for "*new modes of treating potatoes in order to their being converted into various articles of food, and new apparatus for drying, applicable to that and other purposes.*"—November 25; six months.

William Henry Bailey Webster, of Ipswich, Surgeon, for "*improvements in preparing skins and other animal matters, for the purpose of tanning, and in the manufacture of gelatine.*"—November 25; six months.

Oliver Louis Reynolds, of King Street, Cheapside, Merchant, for "*certain improvements in machinery for producing stocking fabric or framework knitting.*" Communicated by a foreigner residing abroad.—November 25; six months.

Nathaniel Batho, of Manchester, Engineer, for "*certain improvements in machinery, tools, or apparatus, for planing, turning, boring, or cutting metals, and other substances.*"—November 26; six months.

Frederick Theodore Philippi, of Bellfield Hall, Calico Printer, for "*certain improvements in the art of printing cotton, silk, and other woven fabrics.*"—November 25; six months.

James Lee Hannah, of Brighton, Doctor of Medicine, for "*an improvement or improvements in fire-esc apes.*"—November 25; six months.

Robert Roberts, of Bradford, Blacksmith, for "*a new method or process for case hardening iron.*"—November 25; six months.

Henry Walker Wood, of Chester Square, Gentleman, for "*an improvement in producing an uneven surface in wood and other substances.*" Communicated by a foreigner residing abroad.—November 25; six months.

TO CORRESPONDENTS.

Notice.

The present Number concludes the Third Volume. The Title, Preface, and Index will be given extra with the next month's Journal.

Vols. I, II, and III, may be had, bound in cloth, price £1 each Volume.

"A Constant Reader." *We have not seen the carriage.*

We have received two other letters besides the one inserted respecting Mr. Mansel's proposition for using marbles to check the lengths of the chain; we think it unnecessary to publish any other than the one by a "Surveyor."

James Inglis's *letter commenting on our remarks, regarding his conduct, in last month's Journal, we must decline publishing. We are at all times disposed to lend our aid in crushing plagiarism; in doing so we must be supported by facts, and no part of the statement should contain any matter but what could be fully proved in a court of law, to which we render ourselves liable to be brought, when vindicating any particular interest, or exposing piracy. Mr. Inglis stated in his letter, that his assertions could be supported by written documents, which, upon investigation, turned out not to be the case. We therefore cannot allow any further correspondence on the subject of "Tide Gauges," unless it is the wish of either Mr. Mitchell or Mr. Bunt.*

A Road Engineer. *We shall attend to the Report on Turnpike Roads next month.*

Books received;—Account on the London and Birmingham Railway; Parsey on Perspective; Williams on Combustion; Pambour on the Steam Engine.

Communications are requested to be addressed to "The Editor of the Civil Engineer and Architect's Journal," *No.* 11, *Parliament Street, Westminster.*

Books for review must be sent early in the month, communications on or before the 20th (if with drawings, earlier), and advertisements on or before the 25th instant.
